Commercial History.—The commerce of the world is supplied with camphor from China, Japan, and Formosa, the great bulk of the product coming from the latter island. After the annexation of Formosa by the Japanese, that Government, led by the unnecessary destruction of the camphor trees of the island, the inferiority of the camphor obtained, and the waste of the processes employed, and especially by the desire for revenue, made a governmental monopoly of the camphor trade which went into operation in 1900. From the first it was found necessary to afford military protection to the gatherers, from the abounding savage tribes, and during the Russo-Japanese war irregularities in this regard are said to have greatly diminished the product and to have caused a marked rise in the price of camphor. The camphor is sold by the Japanese government through a single London firm or company, Samuel Samuels, with sub-agencies at Hamburg, New York, and perhaps other cities. From these agencies refiners in different parts of the world buy it by contract for a year at a time. The statement freely made that camphor is sold at a fixed price by the Japanese government is incorrect, and the extraordinary rise of camphor in price is shown by the fact that in Nov., 1895, the average wholesale price of refined camphor was 58 cents per pound; in Nov., 1900, 62.5 cents per pound; in Nov., 1905, 83 cents per pound, and in the importations of crude camphor from Japan and Formosa are about 4,000,000 kilos annually. (See *Schim. Rep.,* April, 1914, 36.) Camphor is now cultivated on a commercial scale in Florida. According to an article in the *Oil, Paint, and Drug. Rep.,* Feb. 26, 1917, p. 18, one grove in Florida produces 40 tons of crude camphor annually.

The importations of crude camphor into the United States for 1916 were 4,574,430 pounds, and of refined and synthetic camphor 1,806,184 pounds.

There are two very distinct varieties of the crude camphor—namely, the Chinese and the Japanese, the Japanese camphor being divided into the Japanese camphor proper and the Formosa camphor. Of the two commercial varieties the Chinese comes in chests lined with lead, each containing about 130 pounds. It occurs in small grains or granular masses, of a dirty white color, frequently mixed with impurities. Japanese camphor (formerly known as *Dutch camphor* or *"tub camphor"* because it was exported through Batavia) is sent into market in tubs, covered with a peculiar matting, and in its general aspect resembles Chinese camphor. The value and purity of both

Chinese and Japanese camphor vary greatly in different specimens, but recently much of the Chinese crude camphor has been whiter and cleaner than the Japanese. It is always small grained and yields on sublimation crystals much smaller than are obtained from Japanese camphor, and is therefore less esteemed. A dark inferior grade of camphor is also obtained in the United States from commercial oil of camphor.

Sumatra Camphor. Borneo Camphor. Dryobalanops Camphor. Bhimsaim Camphor. Baros Camphor. Borneol.—This camphor is produced in the islands of Sumatra and Borneo, by *Dryobalanops Camphora* Coleb. This tree is very large, often exceeding one hundred feet in height, with a trunk six or seven feet in diameter, and ranks among the tallest and largest trees in India. (*A. J. P.,* xxiv, 329.) It is found in Sumatra and Borneo, and is abundant on the northwest coast of the former island. The camphor exists in concrete masses, which occupy longitudinal cavities or fissures in the heart of the tree, from a foot to a foot and a half long, at certain distances apart. The younger trees are generally less productive than the old. The only method of ascertaining whether a tree contains camphor is by incision. A party proceed through the forest, wounding the trees until they find one which will answer their purpose; and hundreds may be examined before this object is attained. When discovered, the tree is felled and cut into logs, which are then split, and the camphor removed by means of sharp-pointed instruments. It is stated that the masses are sometimes as thick as a man's arm, and that the product of a medium-sized tree is nearly eleven pounds; of a large one, double that quantity. The trees which have been wounded and left standing often produce camphor seven or eight years afterward. Ida Pfeiffer states, in her *Second Journey Round the World* (Am. ed., p. 183), that the camphor is also found in a concrete state under the bark and is swept down with long brooms. The whole tree is pervaded more or less by the camphor or the oil. The wood retains a fragrant odor, and, being on this account less liable to the attacks of insects, is highly esteemed for carpenter work.

Borneo camphor resembles in appearance ordinary camphor, but has, according to Christison, a specific gravity of 1.009, and sinks in water. Its odor is also distinctly different from that of camphor. It usually pulverizes without the addition of alcohol, is less volatile than ordinary camphor and does not crystallize in the interior of the bottles in which it is kept. It fuses at 206° C. (402.8° F.) and boils at 212° C. (413.6° F.); is dextrogyrate; has a formula of $C_{10}H_{17}(OH)$; and by the action of boiling nitric acid is converted into common camphor. It does not reach European commerce, being largely consumed in the Batta provinces, especially in funeral rites; and any that is exported is bought up at enormous prices for China, where it is preferred for embalming purposes on account of its being less volatile than the ordinary drug.

Borneo camphor is also produced in Johore, a province of the Malay peninsula, where it is sold in four qualities. The first is composed of transparent crystals, generally a quarter of an inch and upwards in length; the second of brown crystals, inferior in size; the third of powdery coherent and slightly colored grayish crystals, which resemble Japanese camphor; the fourth quality is brownish, pulverulent, and looks like seashore sand. (See *P. J.,* xvii.)

Ngai camphor is yielded by the *Blumea balsamifera* DC. (Fam. *Compositæ*) which occurs in India, China, Formosa, etc. The crude drug is known to the Chinese as *ngai-fêu,* and when refined in Canton as *ngai-p'ien.* About ten thousand pounds annually are exported from Canton. The refined camphor in appearance, odor, hardness, specific gravity, and volatility agrees almost precisely with Borneo camphor. According to Plowman, it has the chemical composition of Borneo camphor, but differs from it in its alcoholic solution, being lævogyrate, and in being converted by boiling nitric acid into a substance thought to be identical with the stearoptene of *Chrysanthemum Parthenium* Pers.

The physiological action of *Borneo* and *Ngai camphor* and of artificial *borneol* has been studied by R. Stockman (*J. P.,* 1888, ix) who finds that the action of the three substances is practically identical and closely resembles that of true camphor. The results obtained by A. Lapin (*Med. Age,* 1894, xii) confirm those of Stockman, and show that in its proper dose the drug increases the energy of the heart, and that in frogs it is an especial motor nerve paralyzant.

Artificial Camphor.—Camphor can be made artificially by the oxidation of *camphene,* $C_{10}H_{16}$, with chromium trioxide mixture. Camphene is obtained from either *pinenehydrochloride* (so-called artificial camphor) or from bornyl chloride by treatment with alcoholic potash, and is a solid crystalline mass, fusing at 49° C. (120.2° F.). In the patented process of Nathan Thurlow, camphor is made by submitting oil of turpentine to the action of anhydrous oxalic acid in steam-jacketed reaction tanks. The liquid mass, containing *pinyl oxalate* and *pinyl formate,* is then distilled in the presence of an alkali with live steam, the resultant products being camphor, Borneol camphor, and certain oily products, which are separated from one another and purified by a somewhat complicated process. It is stated that turpentine yields in this process from 25 to 35 per cent. of its weight, and that oil of lemon and other essential oils, and terpenes are obtained as secondary products. This artificial camphor is either optically inactive or has a very slight dextrorotation, but in general physical properties exactly resembles natural camphor. So far, however, it seems to be difficult to work the process upon a large scale and the artificial product has had no effect upon the general camphor market. Camphor can also be produced from isoborneol, by the action of oxidizing mixtures. The method patented in France, which

is said to yield from 95 to 100 per cent. of camphor, consists in suspending ten kilogrammes of isoborneol in ten kilogrammes of benzol, and adding ten kilogrammes of potassium permanganate dissolved in one thousand liters of water, until the color of the permanganate is discharged. The camphor produced is separated by distillation and crystallized from petroleum benzin. (*Chem. Ztg.*, 28.)

Refined Camphor.—The process for refining camphor was first practised in Europe by the Venetians, who probably derived it from the Chinese. It was afterwards transferred to the Dutch, who long enjoyed a monopoly of this business; and it is only within recent years that the process has been generally known. It is now practised largely in this country, and the camphor refined in our domestic establishments is equal to any formerly imported. Crude camphor is mixed with about one-fiftieth of quick-lime, and exposed, in an iron vessel placed in a sandbath, to a gradually increasing heat, by which it is melted and ultimately converted into vapor, which condenses in a suitable receiver. Refined in this manner, it is usually in the form of large circular cakes, one or two inches thick, slightly convex on one side and concave on the other, and perforated in the centre. Much refined camphor comes into the market in the form of compressed blocks, this being especially true of camphor refined in Philadelphia and Japan. It is stated that in Japan the refining of camphor is done by the Government and also by individuals, the process being probably that employed in the Philadelphia laboratories, as the first refining of camphor was done in Japan by a man who had been thoroughly educated in these laboratories. Japanese refined camphor occurs in rather thin, oblong cakes, enclosed in small tin boxes which have been hermetically sealed by a paper pasted over their edges. Camphor is refined in Philadelphia as follows: The vessels in which the camphor is put are of cast iron, circular, from 12 to 15 inches or more in diameter, and 4 inches deep, with perpendicular sides, and a ledge at top, on which the cover rests. This consists of sheet iron, with a hole through the center about an inch in diameter, over which a small hollow cone of sheet iron is placed loosely. The crude camphor mixed with the lime, the object of which is said to be to combine with the moisture present, which interferes with the due solidification of the camphor vapor, is placed in the iron vessels described, of which from 20 to 50 are arranged in a long sand bath. Heat is then applied until the camphor melts, after which the temperature is kept as nearly uniform as possible, so that the vaporization may take place regularly, without violent ebullition. The vapor condenses on the lower surface of the lid, and care is taken, by the occasional removal of the iron cone, and clearing of the opening by means of a knife, to allow the escape of any accidental excess of the vapor. A study of natural and synthetic camphor, by P. A. Houseman, giving a complete review of all processes for producing the synthetic article and illustrated with structural formulas, is found in *A. J. P.*, 1915, p. 49.

Properties.—"Camphor occurs in white, translucent masses or granules of a tough consistence and having a penetrating, characteristic odor, and a pungent, aromatic taste. It is readily pulverizable in the presence of a little alcohol, ether or chloroform. Camphor is slightly soluble in water and freely soluble in alcohol, chloroform, ether, carbon disulphide, petroleum benzin, or in fixed or volatile oils. Specific gravity: about 0.990 at 25° C. (77° F.). Camphor melts between 174° and 177° C. (345.2° and 350.6° F.). The specific rotation $[a]_D$ of Camphor in a solution in alcohol at 25° C. (77° F.) is between $+41°$ and $+42°$ in a 200 mm. tube, containing 10 Gm. of Camphor in each 100 mils of solution. The alcohol must be of the strength of about 95 per cent. by volume. It volatilizes at ordinary temperatures. On gradually heating about 2 Gm. of Camphor, it sublimes without carbonization and without leaving more than 0.05 per cent. of ash. A solution of Camphor in petroleum benzin (1 in 10) is clear (*moisture*). Hold the looped end of a piece of clean copper wire in a non-luminous flame until it glows, without coloring the flame green, then dip the loop into Camphor, ignite the adhering Camphor, and hold it so that the liquid burns outside of a non-luminous flame. On slowly bringing the flame from the burning Camphor on the loop in contact with the lower outer edge of the non-luminous flame, no green tinge is discernible (*chlorinated products*)." *U. S.*

"Colorless, transparent crystals or crystalline masses of tough consistence; also in rectangular tablets or in pulverulent masses known as 'flowers of camphor.' Penetrating and characteristic odor; taste pungent and somewhat bitter, followed by a sensation of cold. Specific gravity about 0.995. Melting point about 175° C. (347° F.). Soluble in about 700 parts of *water*, in 1 part of *alcohol* (90 per cent.), in 0.25 part of *chloroform*, and in 4 parts of *olive oil*; very soluble in *ether*. Burns readily with a bright smoky flame, volatilises even at ordinary temperatures, and sublimes without residue when heated. Forms a liquid when triturated with chloral hydrate, menthol, phenol, thymol, and certain other substances. A solution of 5 grammes in sufficient *alcohol* (90 per cent.) to produce 20 millilitres exhibits at 15.5° C. (60° F.) an *optical rotation* of about $+10°$ (distinction from synthetic camphor)." *Br.*

Camphor has a peculiar, strong, penetrating, fragrant odor, and a bitter, pungent taste, with a slight sense of coolness. It is beautifully white and pellucid, somewhat unctuous to the touch, brittle, and yet possessed of a tenacity which renders its reduction to a fine powder very difficult, unless its cohesion be overcome by the addition of a minute proportion of alcohol, ether, chloroform, glycerin, essential or fatty oils, or other volatile liquid for which it has an affinity. It may be obtained in powder by pulverizing with an equal weight of sugar,

by precipitating the tincture with water, or by grating and afterwards sifting it, or by sublimation. A still better plan is to dissolve camphor in one and a half parts of alcohol, and pour this solution with stirring into four parts of water. Collect the precipitate, wash with water, and dry. By noting the quantity of camphor used, the amount left dissolved in the diluted alcohol can be calculated, and this solution used in making tincture. The fracture of camphor is shining, and its texture crystalline. Its sp. gr. varies from 0.9857 to 0.996. When thrown in small fragments upon water, it assumes singular circulatory movements, which cease upon the addition of a drop of oil; and this property has been applied to the detection of grease in liquids, a very small proportion of which is sufficient to prevent the movements. Its volatility is so great that, even at ordinary temperatures, it is wholly dissipated if left exposed to the air. When it is confined in bottles, the vapor condenses on the inner surface, and, in large bottles partially filled, sometimes forms, after long standing, large and beautiful crystals. It melts at 175° C. (347° F.), boils at 204° C. (399.2° F.), and, in closed vessels, sublimes unchanged.

When allowed to concrete slowly from the state of vapor, it assumes the form of hexagonal plates. It is not altered by air and light. It readily takes fire, burning with a brilliant flame, with much smoke, and without residue. Water triturated with camphor dissolves, according to Berzelius, not more than a thousandth part; which, however, is sufficient to impart a decided odor and taste to the solvent. By the intervention of sugar or magnesia a much larger proportion is dissolved. (See *Aqua Camphoræ.*) Carbon dioxide increases the solvent power of water, as also does the spirit of nitrous ether. Ordinary alcohol will take up 75 per cent. of its weight of camphor, which is precipitated upon the addition of water. Berzelius states that 100 parts of alcohol, of the sp. gr. 0.806, dissolve 120 parts at 10° C. (50° F.). It is soluble without change in ether, the volatile and fixed oils, strong acetic acid, and diluted mineral acids, and is extremely soluble in chloroform. Nitric acid on prolonged boiling with camphor oxidizes it into *camphoric acid,* $C_{10}H_{16}O_4$ (see page 1301), and *camphoronic acid,* $C_9H_{14}O_6$. Schwanert's *camphresinic acid,* $C_{10}H_{14}O_{12}$, is, according to Kachler, a mixture of these two. Sulphuric acid in the proportion of ten parts to one gives, when heated with camphor, an oil isomeric with camphor, boiling at 200° C. (392° F.), and yielding a solid camphor when distilled repeatedly over potassium hydroxide. Sulphuric acid, in the proportion of four to one with camphor, gives, according to Chautard, a volatile product which he calls *camphrene,* and to which Schwanert gives the formula $C_9H_{14}O$. Kachler (*Ann. Ch. Ph.,* 164, p. 90) considers, however, that camphrene is only *phorone* (a condensation product of acetone) with slight impurities. Alcoholic potassium hydroxide solution heated with camphor gives a derivative called *campholic acid,* $C_{10}H_{18}O_2$, a white solid, fusing at 95° C. (203° F.), and boiling at 250° C. (482° F.). Resins unite with camphor, forming a soft tenacious mass, in which the odor of the camphor is sometimes almost extinguished, and frequently diminished; and a similar softening effect results when it is triturated with the concrete oils. Exposed to a strong heat, in closed vessels, camphor is resolved into carbonic acid gas and hydrocarbons, among which cymol is especially to be recognized.

Camphor, $C_{10}H_{16}O$, and borneol, $C_{10}H_{18}O$, are classified together as belonging to the group called in general *camphors,* which occur with the *terpenes* or essential oils, $C_{10}H_{16}$, and are to be considered as oxidation products of these latter.

Borneol is an alcohol, yielding esters when heated to about 200° C. (392° F.) with organic acids. It is a secondary alcohol, and therefore contains the group CH.OH linked to a more complex group. Secondary alcohols by oxidation yield *ketones,* by the change of the CH.OH group to CO. Common camphor bears this relation to borneol, and is therefore considered as a ketone, and can be formed from borneol by the action of mild oxidizing agents. The action of metallic sodium, on the other hand, upon common camphor, $C_{10}H_{16}O$, yields borneol, $C_{10}H_{18}O$.

Genuine camphor is said to be sometimes adulterated with the artificial, which may be detected by the action of ammonia upon its alcoholic solution, causing a flocculent precipitate, which does not redissolve, and the quantity of which is proportionate to that of the artificial product in any mixture of the two. (*A. J. P.,* xxxiv, 189.) As a means of distinguishing camphor from the artificial camphor resulting from the reaction between the oil of turpentine and hydrochloric acid, J. W. Bailey recommends that a drop of alcohol, holding in solution a little of the camphor to be tested, be allowed to evaporate on the slide of a microscope. The crystals then formed produce with polarized light, beautiful colors, if of natural camphor, but not, if of the artificial. (*Neues Repertorium,* xvi, 763, 1867.)

Uses.—Locally camphor is irritant, with probably a benumbing influence upon the peripheral sensory nerves, and somewhat antiseptic. It is absorbed through mucous membranes not very readily, but easily from subcutaneous tissue. It combines in the body with glycuronic acid and is eliminated in this combination by the kidneys. The systemic action of camphor is not well understood. In frogs it is depressant to the spinal cord and produces no motor disturbance except gradually increasing paralysis. In the mammalia, including man, it causes convulsions which are apparently due to an affect upon the motor tract of the brain. It appears also to have some stimulant action upon the intellectual centers and antagonizes the somnifacient drugs. On the other hand in conditions of nervous excitement it will frequently produce a sensation of quietude. The effects of

camphor upon the circulation have been the subject of an immense amount of scientific investigation but with very contradictory results. The majority of authorities have found that the drug increases the force of the cardiac contractions in cold-blooded animals, but in the studies upon warm-blooded animals the results have been so contradictory that it seems impossible to harmonize them. Most investigators have found that camphor does not produce any consistent change in the blood pressure until large doses are given, when it is likely to cause a fall, but on the other hand, Pilcher and Sollman (*J. P. Ex. T.*, 1915, vi, p. 349) have found that in the great majority of cases it causes a definite rise in the blood pressure. While Gottlieb (*Z. E. P. T.*, 1905, ii) and others have obtained evidence of a stimulant action upon the heart muscle of warm-blooded animals, the majority of experimenters have been unable to determine such an effect. (For review of the literature on this subject, see *J. P. Ex. T.*, 1914, v, p. 571.) On the other hand, the clinical evidence of the stimulating effect of camphor upon the circulation seems incontestable. In cases of heart failure whether due to diseases of the heart itself or secondary to infectious fevers, such as *typhoid* or in *pneumonia*, it is one of the most valued excitants that we possess. In the latter infection its value is not merely that of a circulatory stimulant, but it seems to have some direct restraining influence upon the growth of pneumococci. Several investigators have found that it will save a large proportion of the lower animals experimentally affected with pneumococcus.

Camphor is used in medicine internally for its calmative influence in *hysteria, general nervousness* and *neuralgia;* as a cardiac stimulant in all forms of heart failure, especially those occurring during low fevers and in pneumonia; and in the treatment of *serous diarrheas.* Externally it is widely employed as a counter-irritant in *sprains, rheumatic affections, bronchitis,* and other inflammatory conditions. It is also employed as a local application, especially in conjunction with menthol or phenol, in inflammations of the upper respiratory tract.

When a profound influence is desired, as in heart failure, it is necessary to give the drug hypodermically. For this purpose from three to five grains may be dissolved in twenty to thirty minims of sterile olive oil. The effect of a single injection lasts usually about two hours. In nervous diseases it may be given in substance, in capsule, or as the spirit; the water contains so little camphor that it is scarcely more than a vehicle.

Dose, two to five grains (0.13–0.32 Gm.).

CAMPHORA MONOBROMATA. U. S.

MONOBROMATED CAMPHOR Camph. Monobrom.

(kăm′phọ-rą mŏn-ọ-brō-mā′tą)

"Ortho-monobromcamphor [$C_{10}H_{15}OBr$ or $C_8H_{15}Br.CO = 231.04$]. Preserve it in well-closed containers, protected from light." *U. S.*

Bromated Camphor, Brominated Camphor, Bromcamphor, Bromo-camphor; Camphre Monobromé, *Fr. Cod.;* Monobrom Camphor, Bromkampher, Kampher-monobromid, *G.;* Canfora monobromata, *It.;* Alcanfor monobromado, Bromuro de alcanfor, *Sp.*

This substance was discovered in 1861 by Th. Swarts, who prepared it by heating dibromide of camphor in a sealed tube to 100° C. (212° F.). It may also be made by heating bromine and camphor in the proper chemical proportions for three hours in a sealed tube, on a water bath. The crystalline mass is washed with water, recrystallized from alcohol after treatment with animal charcoal, washed with an alcoholic solution of potassium hydroxide, then with much water, and finally recrystallized from a mixture of alcohol and ether. It is very easy to prepare the monobromide on a small scale in this way. There is, however, at all times a very great pressure upon the inside of the tube, and the attempt to practise the method upon a large scale is very likely to result in shattering the tubes. This has led to numerous experiments as to the best method of preparing it. (See *Chem. News,* 1896, 208.) Maisch's method is as follows: Introduce 4 ounces of bromine gradually into a retort in which 13 ounces of camphor have been previously placed. In 15

or 20 minutes a brisk reaction will commence. When this subsides, 8 or 9 ounces more of bromine are to be poured in, in four portions, waiting after each addition until the reaction ceases. The liquid in the retort is now to be heated to about 132° C. (270° F.), then cooled, and sufficient petroleum benzin added to dissolve the crystalline mass. The crystals which are formed on cooling may be purified by recrystallization from benzin or hot alcohol. (*A. J. P.*, 1872, 339.) Various modifications of this process have been proposed. J. U. Lloyd (*A. J. P.*, April, 1875) directs the addition of water to the camphor and bromine in the retort, and boils the mixture for two hours, or until all the water is evaporated. Then the contents are poured into a dish and treated with warm alcohol, and allowed to crystallize, the mother liquor being drained off and the product recrystallized from hot alcohol. C. C. Keller (*S. W. P.*, 1880, p. 50) uses chloroform (instead of water, as proposed by Lloyd) with the camphor and bromine, and washes the crystals with absolute alcohol, crystallizing them finally from an ethereal solution. 300 parts of camphor yield 340 parts of monobromated camphor, the theoretical yield being about 456 parts.

Properties.—"Monobromated Camphor occurs in colorless, prismatic needles or scales, or as a powder having a mild but characteristic, camphoraceous odor and taste; permanent in the air. It is decomposed by prolonged exposure to sun-light. One Gm. of Monobromated Camphor dissolves in 6.5 mils of alcohol, 0.5 mil of chloroform, and in 1.6 mils of ether at 25° C. (77° F.); almost insoluble in water. It melts between 74° and 76° C. (165.2° and 168.8° F.). Heat a mixture of about 0.1 Gm. each of Monobromated Camphor and silver nitrate and 2 mils each of nitric acid and sulphuric acid until nitrous vapors are no longer evolved; a yellowish precipitate of silver bromide is obtained. Incinerate about 2 Gm. of Monobromated Camphor; not more than 0.05 per cent. of ash remains. Shake about 0.5 Gm. of powdered Monobromated Camphor with 10 mils of distilled water and filter. The filtrate is neutral to litmus and is not rendered more than slightly opalescent by the addition of a few drops of silver nitrate T.S. (*soluble bromide*)." *U. S.*

Uses.—Monobromated camphor was first proposed as a medicine by Deneffe, and has been used as a nerve sedative in *delirium tremens, hysteria, convulsive irritation* of teething, *sleeplessness*, etc. According to the experiments of Bourneville (*Prog. Med.*, 1874) and of Lawson, it produces in mammals muscular weakness, passing into paralysis, very decided progressive reduction of temperature, decrease in the respiration rate, sleep passing into stupor, and finally death. Bourneville states that the vessels of the ear and eyelids in the rabbit are contracted. Its therapeutic action resembles, but is not identical with, that of other bromides; in the experience of H. C. Wood, it has seemed to be of value in *spermatorrhea*. It is not safe to give it too freely, as in some cases its ingestion has been followed by epileptiform convulsions. The emulsion may be made by dissolving it in six times its weight of expressed oil of almonds, and then forming an emulsion with gum and water in the usual manner.

Elixir of Monobromated Camphor is proposed by Munday. (*P. J.*, March 3, 1877.) Monobromated camphor 3 parts, alcohol (90 per cent.) 120 parts, orange-flower water 80 parts, glycerin 100 parts. Mix the alcohol and glycerin; dissolve the monobromated camphor by the use of a gentle heat, and add the orange-flower water. It contains 1 per cent. of monobromated camphor.

Dose, two to five grains (0.13–0.32 Gm.), repeated as required.

CANNABIS. U. S. (Br.)

CANNABIS Cannab. [Indian Hemp Cannabis Indica U. S. VIII, Guaza, Ganjah]

(kăn'na-bĭs)

"The dried flowering tops of the pistillate plants of *Cannabis sativa* Linné, or of the variety *indica* Lamarck (Fam. *Moraceæ*), freed from the thicker stems and large foliage leaves and without the presence or admixture of more than 10 per cent. of fruits or other foreign matter. Cannabis, made into a fluidextract in which *one hundred mils* represent *one hundred grammes* of the drug, when assayed biologically, produces incoördination when administered to dogs in a dose of not more than 0.03 mil of fluidextract per kilogramme of body weight." *U. S.* "Indian Hemp consists of the dried flowering or fruiting tops of the pistillate plant of Cannabis sativa, *Linn.*, grown in India; from which the resin has not been removed." *Br.*

Cannabis Indicæ, *Br.*; Hemp, Indian Hemp; **Herba Cannabis Indicæ**; Chanvre, *Fr. Cod.*; Chanvre de l'Inde, *Fr.*; Indischer Hanf, *G.*; Cañamo, *Sp.*

For many years the official *cannabis* was restricted to the drug which was used for centuries in India. The reason for this was that the Indian cannabis was more uniformly active. Recently the Indian Government has placed a high tax on every pound of the drug grown. The result has been that other markets have been sought and the hemp plant has been grown in other parts of Asia, Africa and America. While of course, much of this material is not equal to that grown in India yet the fact that it can be grown, as shown by experiments in the United States (see Hamilton, *J. A. Ph. A.*, 1913, ii; 1915, iv, 389) of a very high quality has caused the framers of the U. S. Pharmacopœia to permit the use of a cannabis, no matter where it may be grown, provided it comes up to the biological standard as given in the definition. Physiologically active cannabis is obtained at the present time not only from India, but Africa, Turkey, Turkestan, Asia Minor, Italy, Spain and the United States.

The *Cannabis sativa*, or hemp plant, is an

annual, from four to eight feet or more in height, with an erect, branching, angular stem. The leaves are alternate or opposite, and digitate, with five to seven linear-lanceolate, coarsely serrated segments. The stipules are subulate. The flowers are axillary; the staminate in long, branched, drooping racemes; the pistillate in erect, simple spikes. The stamens are five, with long pendulous anthers; the pistils two, with long, filiform, glandular stigmas. The fruit is ovate and one-seeded. The whole plant is covered with a fine pubescence, scarcely visible to the naked eye, and somewhat viscid to the touch. The hemp plant of India has been considered by some as a distinct species, and named *Cannabis indica;* but the most observant botanists, upon comparing it without cultivated plant, have been unable to discover any specific difference. It is now, therefore, regarded merely as a variety, and is distinguished by the epithet *indica.* Pereira states that in the female plant the flowers are somewhat more crowded than in the common hemp, but that the male plants in the two varieties are in all respects the same.

C. sativa is a native of the Caucasus, Persia, and the hilly regions in Northern India. It is cultivated in many parts of Europe and Asia, and largely in our Western States. It is from the Indian variety exclusively that the medicine was formerly obtained, the heat of the climate in Hindostan apparently favoring the development of its active principle. H. C. Wood, many years ago, obtained a parcel of the male plant of *C. americana* (*C. sativa*) from Kentucky, made an alcoholic extract of the leaves and tops, and, upon trying it on the system, found it effective in less than a grain, and, having inadvertently taken too large a dose, experienced effects which left no doubt of the powers of the medicine, and of the identity of its influence with that of the Indian plant. (*Proc. Am. Philos. Soc.,* vol. xi, p. 226.) The results obtained by H. C. Wood have been confirmed by a number of observers.

The fruits or "so-called" seeds, though not now official, have been used in medicine. They are from three to five millimeters long and about two millimeters broad, roundish-ovate, somewhat compressed, of a shining ash-gray color, and of a disagreeable, oily, sweetish taste. For a comprehensive monograph on the morphology of cannabis fruits, as well as their history and chemical composition, see Tschirch, "*Handbuch der Pharmakognosie,*" p. 555. They yield by expression about 20 per cent. of a fixed oil, which has the drying property, and is used in the arts. They contain also uncrystallizable sugar and albumen, and when rubbed with water form an emulsion, which may be used advantageously in inflammations of the mucous membrane, though without narcotic properties. The seeds are much used as food for birds, as they are fond of them. They are generally believed to be in no degree poisonous; but Michaud relates the case of a child in whom serious symptoms of narcotic poisoning occurred after taking a certain quantity of them. It is probable that some of the fruit eaten by the child was unripe, as in this state it would be more likely to partake of the peculiar qualities of the plant. (*Ann. Thér.,* 1860.)

In Hindostan, Persia, and other parts of the East, hemp has long been habitually employed as an intoxicating agent. The parts are the tops of the plant, and a resinous product obtained from it. *Bhang* is the selected, dried and powdered leaves. *Ganjah* or *gunjah* is the tops of cultivated female plants, cut directly after flowering, and formed into round or flat bundles from two to four feet long by three inches in diameter. It is stated that in the province of Bengal great care is taken to eradicate the male plants from the fields before fertilization of the female, and that thereby the yield and quality of the resin is greatly increased. In Bombay this matter is commonly neglected, so that Bengal ganjah is much superior to Bombay ganjah. It is recognized in India that ganjah rapidly deteriorates on keeping, that which is one year old being not more than one-quarter as potent as the fresh drug, while two-year-old ganjah is practically inert and is required by the Indian government to be burned in the presence of excise officers. It is probable, however, that much old ganjah finds its way into the markets of the world. All importations of ganjah or hemp from India should be made directly after the harvesting of the new crop in April or May, and the extract should be prepared at once and kept in hermetically sealed jars. There is on the surface of the plant a resinous exudation to which it owes its stickiness. According to Hooper (*P. J.,* 1909, lxxxi, 347) only small amounts of charas are raised in India, that which is being consumed there being mostly imported. The method of collection in Baluchistan is to gently rub the dried plant between carpets. The dust which comes off contains the active principle and is known as "rup." The second shaking produces an inferior variety, known as "tahgalim," and the third shaking is known as "ganja." In Nepal the plant is squeezed between the palms of the hands, and the resin scraped off from the hands. These balls, and also masses formed out of resin mechanically separated from the hemp plant are called *charas* or *churrus.* This is the *hashish* or *hasheesh* of the Arabs.

Hashish is also produced in considerable quantities in Persia by rolling and rubbing the flowers, stalks and leaves of hemp on rough woolen carpets and subsequently scraping off with a knife and making into balls or sticks the adherent resinous substance. The carpets are afterwards washed with water and the extract obtained by evaporation sold at a low price. The dose for smoking of the best hashish is said to be one-fourth to one grain (0.016–0.065 Gm.). The fanatics are affirmed to be generally hashish devotees.

The dealing in hashish in India is said to be a Government monopoly, and a very heavy license is required for the right to even purchase it in quantity. The importation of it into Egypt

is so strongly interdicted that the mere possession of it is a penal offence; H. C. Wood found it, however, readily procurable. It is said to be brought into the country in pigs' bladders, in the Indo-European steamers, and thrown out at night during the passage into the Suez canal, to be picked up by the boats of confederates. Notwithstanding the Governmental interdiction, it is largely used by smoking in Egypt, as an intoxicant. The statement of W. E. Dixon (*B. M. J.*, Nov., 1899) that the inhalations of hemp smoke produces great exhilaration and causes muscular fatigue to disappear for the time being is undoubtedly correct, but his further belief that the habit is not apt to grow upon the hemp votary is more doubtful.

Momea or *mimea* is a hemp preparation said to be made in Thibet with human fat. From gunjah the Messrs. Smith, of Edinburgh, obtained a purer resin by the following process: Bruised ganjah is digested, first in successive portions of warm water, until the expressed liquid comes away colorless; and afterwards for two days, with a moderate heat, in a solution of sodium carbonate, containing one part of the salt for two of the dried herb. It is then expressed, washed, dried, and exhausted by percolation with alcohol. The tincture, after being agitated with milk of lime containing one part of the earth for twelve of the gunjah used, is filtered; the lime is precipitated by sulphuric acid; the filtered liquor is agitated with animal charcoal, and again filtered; most of the alcohol is distilled off, and to the residue twice its weight of water is added; the liquor is then allowed to evaporate gradually; and, finally, the resin is washed with fresh water until it ceases to impart a sour or bitter taste to the liquid, and is then dried in thin layers. Thus obtained, it retains the odor and taste of gunjah, which yields from 6 to 7 per cent. of it.

Properties.—Fresh hemp has a peculiar narcotic odor, which is said to be capable of producing vertigo, headache, and a species of intoxication. It is much less in the dried tops, which have a feeble bitterish taste. According to Royle, *churrus* is, when pure, of a blackish-gray, blackish-green, or dirty olive color, of a fragrant and narcotic odor, and a slightly warm, bitterish, and acrid taste. Cannabis is officially described as "in dark green or greenish-brown and more or less agglutinated fragments, consisting of the short stems with their leaf-like bracts and pistillate flowers, some of the latter being replaced with more or less developed fruits; stems cylindrical, of varying length, not more than 3 mm. in diameter, longitudinally furrowed, light green to light brown, strigose-pubescent; leaves digitately compound; leaflets, when soaked in water and spread out, linear-lanceolate, nearly sessile, margin deeply serrate, bracts ovate, pubescent, each enclosing one or two pistillate flowers, or more or less developed fruits; calyx dark green, pubescent and somewhat folded around the ovary or fruit; styles two, filiform and pubescent; ovary with a single campylotropous ovule; fruit light green to light brown, broadly ellipsoidal, about 3.5 mm. in length, finely wrinkled and slightly reticulated; odor agreeably aromatic; taste characteristic. The powder is dark green, giving a strong effervescence on the addition of dilute hydrochloric acid; numerous sharp pointed fragments of upper portion of non-glandular hairs and fragments of bracts and leaves showing yellowish-brown laticiferous vessels, rosette aggregates of calcium oxalate from 0.005 to 0.025 mm. in diameter; non-glandular hairs unicellular, with a very slender pointed apex and a considerably enlarged base containing, usually in the lumen, some calcium carbonate; glandular hairs of two kinds, one with a short, one-celled stalk and the other with a multicellular, long, tongue-shaped stalk, the glandular portion being globular and consisting of from 8 to 16 cells, fragments of fruits with palisade-like, non-lignified sclerenchymatous cells, walls yellowish-brown, finely porous, the lumina usually containing air; tissues of embryo and endosperm with numerous oil globules and aleurone grains, the latter from 0.005 to 0.01 mm. in diameter and consisting of large crystalloids and globoids. The yield of alcohol extractive is not less than 8 per cent. and the alcoholic solution is of a bright green color. Cannabis yields not more than 15 per cent of ash." *U. S.*

The British Pharmacopœia describes Indian cannabis as follows:

"In compressed, rough, dusky-green masses, consisting of the branched upper part of the stem, bearing leaves and pistillate flowers or fruits, matted together by a resinous secretion. Upper leaves simple, alternate, 1–3 partite; lower leaves opposite and digitate, consisting of five to seven linear-lanceolate leaflets with distantly serrate margins. Fruit one-seeded and supported by an ovate-lanceolate bract. Both leaves and bracts bear external oleo-resin glands and one-celled curved hairs, the bases of which are enlarged and contain cystoliths. Strong, characteristic odor; taste slight. When a mixture of 10 grammes of finely powdered Indian Hemp and 100 millilitres of *alcohol* (90 per cent.) is shaken occasionally during twenty-four hours and then filtered, 20 millilitres of the filtrate, evaporated in a flat-bottomed dish, yield a residue weighing, when dried at 100° C. (212° F.), not less than 0.250 gramme. Ash not more than 15 per cent." *Br.*

For a histological description of the leaf by A. R. L. Dohme, see *Proc. A. Ph. A.*, 1897, 569. The Cannabis of the market may consist of fruiting tops and stems and occasionally the staminate tops are admixed with it.

Hooper (*P. J.*, lxxxi, p. 80) describes a method for the chemical standardization of cannabis indica based upon its iodine value. He finds that the alcoholic extract of old samples has a lower iodine value than that from recent specimens, and there is more or less constancy of relation between the age and the iodine value.

For description of the U. S. method of physiological assay, see page 279.

Indian churrus or hasheesh is a hard resinous

mass of a greenish-gray color, containing much gritty earth, and, as it occurs in Egypt, of a feeble, hemp-like odor and taste. Schlesinger found in the leaves a bitter substance, chlorophyll, green resinous extractive, coloring matter, gummy extract, extractive, albumen, lignin, and salts. The plant also contains volatile oil in very small proportion, which probably has narcotic properties. The resin obtained by T. & H. Smith of Edinburgh, in 1846, has been thought to be the active principle, and received the name of *cannabin*. By repeated distillation of the same portion of water from relatively large quantities of hemp renewed at each distillation, M. J. Personne obtained a volatile oil, of a stupefying odor, and an action on the system such as to dispose him to think that it was the active principle of the plant. As the water distilled was strongly alkaline, he supposed that his volatile principle might be a new alkaloid; but the alkaline reaction was found to depend on ammonia; and the liquid obtained proved to be a volatile oil, lighter than water, of a deep amber color, a strong odor of hemp, and composed of two distinct oils, one colorless, with the formula $C_{15}H_{20}$, the other a hydride of the first, $C_{15}H_{22}$, which was solid, and separates from alcohol in plate-like crystals. For the former Personne proposes the name of *cannabene*. It is affirmed that when this is inhaled, or taken into the stomach, a singular excitement is felt throughout the system, followed by a depression, sometimes amounting to syncope, with hallucinations which are generally disagreeable, but an action on the whole slighter and more fugitive than that of the resin. The various substances of alkaloidal nature that have been described by different investigators as found in Indian hemp are now recognized as due to decomposition products of *choline*, which was identified as present by Jahns. (*P. J.*, 1887, xvii, 1049.) *Cannabindon*, $C_8H_{12}O$, is a dark red syrupy liquid obtained by Kobert (*Chem. Ztg.*, 1894, 741) from Cannabis Indica; it is soluble in alcohol, ether and oils; it is affirmed to be narcotic in doses of from half a grain to two grains (0.032–0.13 Gm.). As a result of a reinvestigation of charras (churrus) from Indian hemp, Wood, Spivey, and Easterfield (*J. Chem. S.*, vol. lxix, 539) have found the following principles: 1, a *terpene*, boiling between 150° and 180° C. (302° and 356° F.); 2, a *sesquiterpene*, boiling at 258° to 259° C. (496.4°–498.2° F.); 3, a *crystalline paraffin* of probable formula $C_{29}H_{60}$, melting at 63.5° C. (146.3° F.); and 4, a *red oil*, boiling at 265° to 270° C. (509°–518° F.) under a pressure of 20 mm., to which they give the name *cannabinol*, and the formula $C_{15}H_{24}O_2$. This latter constituent they consider the only active ingredient. It is probably the same substance as the dark red syrup of Kobert, mentioned above under the name cannabindon. The authors found that cannabinol readily underwent superficial oxidation, at the same time losing its toxic activity. Famulener and Lyons (*A. Pharm.*, 1904) believe that the only reliable preparation of cannabis is a fluidextract made from the *fresh* drug. I. Roux (*A. Pharm.*, 1887) has experimented upon extracts made by treating purified extract of hemp with petroleum benzin and ether. The ether extract produced insignificant results. The petroleum extract was excitant and convulsant. The alcoholic extract was a feeble narcotic. The resin "cannabin" of which *cannabinol* is the chief constituent, appears to be active. Fränkel (*A. E. P. P.*, 1903, p. 266) claims to have isolated the active principle of hashish as a pure and chemically well defined body. It has the formula $C_{21}H_{30}O_2$, and is a phenol-aldehyde. It is of a pale yellow color and of a thick consistency. When heated it becomes quite fluid and distils at 215° C. (419° F.), under a pressure of 0.5 mm. It oxidizes in the air, acquiring a brown tint. It responds to Millon's reaction, and can be acetylized, showing thus its phenol character. Fränkel proposes that the name *cannabinol* be given to it and that the term *pseudo-cannabinol* be given to the inactive substance of Wood, Spivey and Easterfield.

Assay.—"Prepare a fluidextract and proceed as directed below." *U. S.*

Attempts have been made to apply physiological tests to the standardization of cannabis indica. Up to the present no means have been suggested for determining the relative potency of different samples of cannabis indica, the physiological test simply demonstrating that the drug possesses a certain indefinite amount of physiological action. This test is carried out upon dogs in the following manner: It is advisable to use the same animal for repeated tests, because the individual susceptibility of the dog varies so greatly, and the experimenter gradually learns the degree of reaction to be expected from a certain dog. A tincture of the specimen to be tested is either evaporated into a soft extract and given in the form of a pill or mixed with an inert absorbing powder and enclosed in a capsule; it must not be given hypodermically. The symptoms caused by cannabis indica in the dog recall those of alcoholism in the human being. There is at first a slight loss of control in the hind legs so that the animal staggers as he walks, later the ataxia becomes so marked that the dog is unable to stand up without leaning against some object, and about this time begins to show distinct drowsiness, and may eventually pass into a heavy sleep.

The details of assay as directed by the U. S. are as follows: "The assay of Cannabis and its preparations has been made a requirement and is based upon the fact that this drug produces certain symptoms of muscular incoördination. The method consists of ascertaining the dose of the preparation to be tested which will produce these symptoms of incoördination in dogs and then adjusting its strength by comparison with a standard preparation.

"*Dogs.*—The animals differ considerably in susceptibility to the drug and therefore it is best to make preliminary tests upon several

dogs with average-sized doses and select from among them the animals which react easily to the drug. As a rule, fox terriers serve very well for the purpose, but any dog may prove satisfactory. It is best to provide at least two dogs for each assay, but if many samples are to be examined more dogs will be needed. The dogs should be at least one year old and in normal health and must be kept under the best sanitary conditions. They may be used repeatedly for the purpose but not at shorter intervals than three days. Each series of tests should be conducted by the same person, who should be perfectly familiar with the peculiarities of each animal in order that he may recognize more certainly deviations from the normal. While the tests are being made the animals should be kept in a perfectly quiet room, free from disturbance and separated so that they cannot see each other.

"*Preparation of the Drug.*—The drug may be given most conveniently in the form of the fluidextract which is administered in gelatin capsules, or the extract made into soft pills may be used; but whichever form is chosen the same should be used for both the standard and the preparation that is to be tested.

"Before administration the animal should not be fed for twenty-four hours in order to hasten absorption. The head of the animal being held, its mouth is opened and the capsule or pill is placed upon the back of the tongue. Usually the drug is easily swallowed when given in this way, but this may be facilitated by giving the animal a small amount of water to drink.

"*Assay.*—An average dose of the known or standard preparation is given to one of the dogs and a like dose of the preparation to be standardized is given the second dog. After one hour both dogs are observed very carefully for symptoms of muscular incoördination. The incoördination is manifested differently in different animals, but in small doses it shows itself most frequently in slight swaying, when the animal is standing quietly, or in some ataxia when it runs about. The observation should be made frequently during the second hour following the administration of the drug.

"The results obtained from the first test should be confirmed after an interval of not less than three days by repeating the administration, but reversing the order, that is, giving the known strength drug to the dog which received that of unknown strength before and *vice versa*.

"In subsequent tests which are carried out, the dose of the preparation of unknown strength is modified so as to produce similar symptoms to those produced by the standard. If the preparation to be tested is below the standard in strength, its dose must be increased, or if it is above strength its dose is lessened until equivalent doses of the two are found. Dogs may be used over long periods of time, even for some years, but occasionally they have to be discarded, as in some cases they seem to learn the effects of the drug and so refuse to stand up. A certain degree of tolerance is sometimes gained which necessitates larger doses.

"*Standard.*—As there is no chemical substance of definite composition which can be adopted as a standard, a Fluidextract of Cannabis or an extract which has been carefully prepared and suitably preserved may be utilized for this purpose. A standard Fluidextract will produce incoördination when administered to dogs in the dose of 0.03 mil for each kilogramme of body weight of dog. When administered in the form of the Extract a dose of 0.004 Gm. for each kilogramme of body weight of dog should produce similar symptoms, and the requirement for a standard tincture is a dose of 0.3 mil for each kilogramme of body weight of dog." *U. S. IX.*

Uses.—Aside from a slight local irritant effect the action of cannabis seems to be limited almost exclusively to the higher nerve centers. In man this is first manifested by a peculiar delirium which is accompanied with exaltation of the imaginative function and later by a remarkable loss of the sense of time. The delirium is often accompanied with motor weakness and diminished reflexes and generally followed by drowsiness. In the dog the earliest manifestation of the drug's action is a slight degree of restlessness which is soon followed by disturbances of equilibrium and later weakness of the legs and drowsiness.

Cannabis is used in medicine to relieve pain, to encourage sleep, and to soothe restlessness. Its action upon the nerve centers resembles opium, although much less certain, but it does not have the deleterious effect on the secretions. As a somnifacient it is rarely sufficient by itself, but may at times aid the hypnotic effect of other drugs. For its analgesic action it is used especially in pains of neuralgic origin, such as *migraine,* but is occasionally of service in other types. As a general nerve sedative it is used in *hysteria, mental depression, neurasthenia,* and the like. It has also been used in a number of other conditions, such as *tetanus* and *uterine hemorrhage,* but with less evidence of benefit. One of the great hindrances to the wider use of this drug is its extreme variability. Formerly many of the preparations of cannabis were inert before they left the manufacturers' hands, and the present requirements of the U. S. P. that the drug be tested upon dogs to insure its activity is an important step in the right direction. But even granted an active preparation when manufactured, so rapidly does the drug deteriorate that by the time the drug reaches the patient it has lost a large proportion of its activity. The only way of determining the dose of an individual preparation is to give it in ascending quantities until some effect is produced. The fluid extract is perhaps as useful a preparation as any; one may start with two or three minims of this three times a day, increasing one minim every dose until some effect is produced. According to C. R. Marshall (*L. L.,* 1897, i, also *J. A. M. A.,* Oct., 1898) the deterioration of cannabis is due to the oxidation

of cannabinol, which he has found to act upon dogs and cats as the crude drug.

Dose, of cannabis, one to three grains (0.065–0.2 Gm.).

CANTHARIDINUM. Br.

CANTHARIDIN

(kăn-thą-rĭ-dĭ′nŭm)

"Cantharidin, $C_{10}H_{12}O_4$, may be obtained from various species of Cantharis or of Mylabris." *Br.*

Cantharidin is the anhydride (lactone) of cantharidic acid and is officially recognized by the Br. Pharm. (1914) and the Swiss and French Pharmacopœias. Preparations made from cantharidin are believed to be more uniform in quality than those made from cantharides because they are made from a definite crystallizable product and it is not always easy to extract all of the cantharidin from powdered Spanish flies by the usual methods, as in making the vinegar, tincture, collodion, cerate or plaster. (See *Cantharis,* page 282.)

E. Dieterich prepares cantharidin by macerating 1000 parts of coarsely powdered cantharides in 1500 parts of acetic ether mixed with 20 parts of sulphuric acid; after adding 40 parts of barium carbonate to neutralize the excess of sulphuric acid, the mixture is exhausted with acetic ether in an extraction apparatus, the liquid is distilled, and the residue, consisting of cantharidin, resin, fat, etc., is set aside for eight days to allow the cantharidin to crystallize; 200 parts of petroleum benzin (sp. gr. 0.740) are then added, gently heated in order to dissolve the fatty matter, the liquid filtered, and the cantharidin washed with petroleum benzin and recrystallized from its solution in 90 per cent. alcohol. If perfectly pure cantharidin is needed, the cantharidin may be dissolved in acetic ether or chloroform and the solution passed through animal charcoal, filtered, and allowed to crystallize. (*J. P. C.,* 1893, 375.) For assay of cantharides for cantharidin see *P. J.,* 1903, 558 and 783.

Properties.—"Colorless glistening crystals, inodorous. Very slightly soluble in *water, petroleum spirit,* or *alcohol* (90 per cent.); more soluble in *chloroform,* in *acetic ether,* and in *acetone;* soluble also in fixed oils. A 0.1 per cent. solution in a fixed oil raises blisters when kept in contact with the skin. Melting point 210° to 212° C. (410°–413.6° F.). Slowly volatilises at 100° C. (212° F.), more rapidly at higher temperatures. Soluble in *solution of sodium hydroxide,* the solution depositing crystals of Cantharidin when acidified. Gently warmed with *sulphuric acid* it yields a colorless solution, from which it is separated unchanged when freely diluted with *water.*" *Br.*

Cantharidin is in the form of white crystalline scales, of a shining micaceous appearance, inodorous, tasteless, almost insoluble in water and in cold alcohol, but soluble in ether, chloroform, benzene, the oils, and in hot alcohol and acetic acid, which deposit it upon cooling. According to Procter it is insoluble in water. Cold alcohol dissolves it slightly, hot alcohol freely. It is more soluble in ether, which also dissolves it more freely hot than cold. Chloroform, cold or hot, is its best solvent; and acetone ranks next to it in this respect. Olive oil, at 121.1° C. (250° F.), dissolves one-twentieth of its weight, and oil of turpentine, boiling hot, one-seventieth; and both deposit the greater portion on cooling. The olive oil solution after deposition vesicates, the terebinthinate does not. Strong acetic, sulphuric, and nitric acids dissolve it, with the aid of heat, and deposit it unchanged on cooling. It is also dissolved by solutions of potassium or sodium hydroxide, and to a small extent by a strong solution of ammonia. (*A. J. P.,* xxiv, 296.) Formic acid is said to be the best solvent. Somewhat different results in relation to the solubility of cantharidin have been obtained by M. E. Rowan. Careful experimentation with distilled water showed that, when agitated for eight days at ordinary temperatures with pure cantharidin, it was capable of dissolving 0.0266 per cent. of that principle; boiling water dissolves 0.297 per cent.; boiling alcohol (99° Tralles) 2.168 per cent. (*J. P. C.,* May, 1873, 409.) It fuses at 210° C. (410° F.), is volatilizable by heat without decomposition, and its vapor condenses in acicular crystals. As determined by the experiments of Wm. A. Guy, the subliming heat of isolated cantharidin is 100° C. (212° F.), or the temperature of boiling water. (*P. J.,* Feb., 1868, 373.)

According to Masing and Dragendorff, cantharidin, $C_{10}H_{12}O_4$, is capable of combining with water, and thus becomes cantharidic acid, $C_{10}H_{14}O_5$, and in this state forms definite compounds with bases, such as $K_2C_{10}H_{12}O_5$ and $Na_2C_{10}H_{12}O_5$, which are crystallizable. These may be obtained by heating cantharidin with an alkaline hydroxide solution. (*J. P. C.,* January, 1868, 79.) Cantharidin itself has been found to combine like an acid with salifiable and earthy bases, forming soluble compounds with potassium, sodium, and lithium hydroxides, salts of very sparing solubility with baryta, strontia, and lime, and with magnesia a salt which, though feebly soluble in water (100 parts of water dissolving only 0.24 of the salt) (see *P. J.,* March 13, 1880), is much more largely dissolved in cold than hot water, and in cold than in hot alcohol. Cantharidin is therefore recognized as the lactone or inner anhydride of cantharidic acid. The potassium salt crystallizes with 3 molecules of water, and is soluble in 25 parts of water. On the addition of strong acids to this solution, cantharidic acid is not precipitated, as might be expected, but the lactone cantharidin. This potassium

salt has been recommended by Liebreich for use in subcutaneous injections in cases of *phthisis*, but is of very doubtful value. The most satisfactory test of cantharidin is its vesicating property. Notwithstanding the insolubility of this principle in water and cold alcohol, the decoction and tincture of cantharides have the medicinal properties of the insect; and Lewis ascertained that both the aqueous and alcoholic extracts act as effectually in exciting vesication as do the flies themselves, while the residue is in each case inert. Cantharidin consequently exists in the insect so combined with the yellow matter as to be rendered soluble in water and cold alcohol. If, as stated by E. Dieterich (1883), formic acid is present in the Spanish fly, it is probable that the solution of the cantharidin is due to its presence. He also showed that cantharidin was not volatilized with the vapor of benzin, a fact which may prove useful in preparing blistering plasters coated with a benzin solution of cantharidin. (*Ph. Centralh.*, 1901, 464.) H. G. Greenish calls attention to the fact that much loss of cantharidin takes place in making the various pharmaceutical preparations, through insufficient exhaustion by the use of the ordinary solvents. He obtained 0.822 per cent. of cantharidin from exhausted residues. Homolka records (*Ber. d. Chem. Ges.*, xix, 1082) the results of an investigation of the chemical decompositions of cantharidin.

Uses.—Cantharidin is used for the same purposes as *Cantharides* (see page 285). Liebreich strongly recommended hypodermic injections of cantharidin in the treatment of *phthisis*, but general clinical experience has not confirmed the value of the remedy. *Liebreich's cantharidal solution* was made by heating 20 mils of water with 0.2 Gm. of cantharidin and 0.4 Gm. of potassium hydroxide until solution was obtained, then adding enough water to make 1000 mils. Of this solution he injected from 0.5 to 1.0 mil at a dose.

Dose of cantharidin is from one-two-hundred-and-fortieth to one-one-hundred-and-twentieth grain (0.00025–0.0005 Gm.).

CANTHARIS. U. S.

CANTHARIDES Canthar. [Blistering Flies, Spanish Flies, Russian Flies]

(kăn'thą-rĭs)

"The dried beetles, *Cantharis vesicatoria* (Linné) De Geer (Fam. *Meloideæ*, Order *Coleoptera*), yielding not less than 0.6 per cent. of cantharidin. Preserve Cantharides in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." *U. S.*

Muscæ Hispanicæ; Cantharide, *Fr. Cod.;* Cantharides, *P. G.;* Spanische Fliegen, Kantharide, Cantharidien, *G.;* Cantaride, Cantarella, Mosca di Spagna, *It.;* Cantaridina, *Sp.*

Cantharis is recognized in all of the European Pharmacopœias, but has been dropped by the British authority, being replaced by Cantharidin which it is stated "may be obtained from various species of Cantharis or Mylabris."

The Br. Add. under the name of *Mylabris* formerly recognized not only the dried beetle, *Mylabris phalerata* Pallas, but also allowed the use in the Colonies of other species of the genus, provided that they yield a similar proportion of cantharidin. Mylabris was characterized in the Br. Add. as "usually an inch (twenty-five millimetres) or rather more long, and three-eighths of an inch (nine millimetres) broad; with two long elytra, each three times as long as broad, black with two broad wavy transverse orange-colored bands and a large orange-colored spot at the base of each; one pair of brown membranous wings."

The term *Cantharis* was employed by the ancient Greek writers to designate many coleopterous insects or beetles. Linnæus gave the title to a genus not including the official blistering insect, and placed this in the genus *Meloë*, which, however, has been since divided into several genera. Geoffrey made the Spanish fly (beetle) the prototype of a new genus, *Cantharis*, substituting *Cincindela* as the title of the Linnæan genus. Fabricius altered the arrangement of Geoffrey, and substituted *Lytta* for *Cantharis* as the generic name. The former was adopted by the London College, and at one time was in extensive use; but, the latter, having been restored by Latreille, is now recognized in the British and U. S. Pharmacopœias, and is universally employed. By this naturalist the vesicating insects were grouped in a small tribe, corresponding very nearly with the Linnæan genus *Meloë*, and distinguished by the title *Cantharidæ*. This tribe he divided into eleven genera, among which is Cantharis. Two others of these genera, *Meloë* properly so called, and *Mylabris*, have been employed as vesicatories. *Mylabris cichorii* is thought to be one of the insects described by Pliny and Dioscorides under the name of cantharides, and is to this day employed in Italy, Greece, the Levant, and Egypt; and another species, *M. pustulata*, is used for the same purpose in China. W. R. Warner has found 500 parts of *M. cichorii* to yield 2.13 parts of cantharidin, which somewhat exceeds the yield of Spanish flies. (*A. J. P.*, xxviii, 195); and R. Wolff has obtained by ethereal extraction more than 4 parts of cantharidin in 500 of the *Lytta aspersa* of Buenos Ayres. The *M. cichorii* has been recently imported to some extent under the name of *Chinese blistering fly* It is black, with the powder blackish gray and free from shining particles; it yielded to Maisch (*Proc. A. Ph. A.*, 1872) 1.016 per cent., and to L. Fahnestock 1.25 per cent. of cantharidin. (*A. J. P.*, 1879.)

Cantharis vesicatoria is one of the *Coleopteræ* or beetles. It is from 15 to 25 mm. long, and of a shining, golden-green color. The head is large and heart-shaped, bearing a pair of stout mandibles and filiform antennæ; the thorax short

and quadrilateral; the wing-sheaths long and flexible, covering brownish membranous wings. (Snyder, *A. J. P.*, 1908, p. 545.) When alive, the Spanish flies have a strong, penetrating, fetid odor, compared to that of mice, by which swarms of them may be detected at a considerable distance. They attach themselves preferably to certain trees and shrubs, such as the white poplar, privet, ash, elder, and lilac, upon the leaves of which they feed. They are most abundant in Spain, Italy, and Southern France, but are found also in all the temperate parts of Europe, and in Western Asia. According to the researches of Lichtenstein, the eggs are laid by the female in the latter part of June in small cylindrical holes made in the ground. A week later the larvæ hatch out. They are a millimeter long, with two long caudal threads, and of a brown color. After many efforts, Lichtenstein succeeded in getting them to feed on the honey contained in the stomach of bees. In a few days they changed into milk-white larvæ, and about a month after this buried themselves in the ground, to assume the chrysalis stage and to hatch out the following spring as perfected beetles. In the wild state the larvæ are said to crawl up flowers and attach themselves to bees or other hymenopterous insects; carried by the bee to the hive, the larvæ feed upon the young bees and the honey and beebread stored up for use. The beetles usually make their appearance in swarms upon the trees in May and June, when they are collected.

The time preferred for this purpose is in the morning, at sunrise, when they are torpid from the cold of the night, and easily let go their hold. Persons with their faces protected by masks, and their hands with gloves, shake the trees, or beat them with poles; and the insects are received as they fall upon linen cloths spread underneath. They are then plunged into vinegar diluted with water, or exposed in sieves to the vapor of boiling vinegar, and, having been thus deprived of life, are dried either in the sun, or in apartments heated by stoves. This mode of killing the flies by the steam of vinegar is as ancient as the times of Dioscorides and Pliny. In some places they are gathered by smoking the trees with burning brimstone. It has been proposed by Lutrand to destroy them by the vapor of chloroform. When perfectly dry, they are introduced into casks or boxes lined with paper and carefully closed, so as to exclude as much as possible the atmospheric moisture. According to Neutwich, the young fly has no vesicating power (*P. J.*, Nov. and Dec., 1870, p. 355); but this is denied by H. Beauregard. (*Ibid.*, xv, 873.)

Cantharides come chiefly from Spain, Southern Russia and Hungary, and other parts of the Mediterranean as Sicily, Poland and Roumania. The Russian flies are most esteemed. They may be distinguished by their greater size, and their color approaching to that of copper.

In the United States are several species of Cantharis, which have been employed as substitutes for *C. vesicatoria* and found equally efficient; but none of them are now recognized by the U. S. Pharmacopœia, even *C. vittata*, which was at one time official, having been discarded. For description of unofficial blistering beetles, see *U. S. D.*, 19th edition, p. 284.

Cantharis vittata. Latreille, *Gen. Crust. et Insect.;* Durand, *A. J. P.*, ii, 274, Fig. 4.—The *"potato fly"* is rather smaller than *C. vesicatoria*, which it resembles in shape. Its length is about six lines. The head is light red, with dark spots upon the top; the feelers are black; the elytra or wing-cases are black, with a yellow longitudinal stripe in the center, and with a yellow margin; the thorax is also black, with three yellow lines; and the abdomen and legs, which have the same color, are covered with a cinerous down. It inhabits chiefly the potato vine, and appears about the end of July or beginning of August, in some seasons very abundantly. It is found on the plant in the morning and evening, but during the heat of the day descends into the soil. The insects are collected by shaking them from the plant into hot water, and are afterwards carefully dried in the sun. They are natives of the Middle and Southern States. This species of Cantharis was first described by Fabricius in the year 1781, and was introduced to the notice of the profession by Isaac Chapman, of Bucks County, Pennsylvania, who found it equal if not superior to the Spanish fly as a vesicatory. The testimony of Chapman has been corroborated by that of many other practitioners. It may be applied to the same purposes, treated in the same manner, and given in the same dose as the foreign insect. W. R. Warner obtained 1.99 parts of cantharidin from 500 parts of this beetle, but by improved methods Fahnestock procured 1⅓ per cent. of the active principle. (*A. J. P.*, xxviii, 195; li, 298.) According to the researches of Jos. Leidy, the vesicating principle resides in the blood, the eggs, and a peculiar fatty matter of certain accessory glands of the generative apparatus (*A. J. M. S.*, Jan., 1869, p. 60); while H. Beauregard (*P. J.*, xv, 873) found that the blood, the seminal vesicles of the male, the eggs, and all parts of the generative organs of the female are active. This insect must not be confounded with the "potato bug" the *Colorado potato beetle* (*Doryphora decemlineata*), which has proved so destructive to potato plants, and which, according to the researches of L. Dembinski (*A. J. P.*, 177, p. 550), contains no cantharidin.

Properties.—"From 15 to 25 mm. in length, 5 to 8 mm. in breadth, oblong, somewhat compressed above; of a brilliant green or bluish-green metallic luster, changing in different parts, especially beneath, to a golden-green; head triangular, separated into two lateral lobes by a faint median line; mandibles stout and partly concealed; antennæ filiform, of 11 conical joints; the upper ones being black; eyes comparatively small; prothorax angulate; legs with five tarsal joints; wings membranous and brownish; elytra or wing sheaths each with two parallel lines and finely wrinkled; odor strong,

disagreeable; taste slight, afterwards acrid. Cantharides with an ammoniacal odor must not be used. The powder is grayish-brown, with shining green particles and a number of long, pointed, 1-celled hairs 0.5 mm. in length and 0.02 mm. in width. Cantharides does not contain more than 10 per cent. of moisture. Cantharides yields not more than 9 per cent. of ash.

"**Assay.**—Introduce 15 Gm. of Cantharides, in No. 40 powder, into a stout bottle of not less than 250 mils capacity, add 150 mils of a mixture of benzene, two volumes, and purified petroleum benzin, one volume, and then add 2 mils of hydrochloric acid. Stopper the bottle tightly, shake it well, and allow it to stand about ten hours. Now gradually warm the bottle and its contents to about 40° C. (104° F.), and maintain it at that temperature with frequent shaking during three hours. Cool the mixture, decant or filter off 100 mils of the clear solution and evaporate this rapidly in a tared beaker or wide-necked flask to a volume of about 5 mils. Now add 5 mils of chloroform to the residue and set it aside in a moderately warm place. When the solvent has all evaporated, add to the crystals 10 mils of a mixture of equal volumes of dehydrated alcohol and purified petroleum benzin, which has previously been saturated with pure cantharidin, allow the mixture to stand during fifteen minutes and then decant the liquid through a pellet of purified cotton. Wash the crystals with successive portions of a saturated solution of cantharidin, similar to that directed above, until it is free from fat and coloring matter, and pass the washings through the same pellet of purified cotton. Then wash the cotton with a very small quantity of warm chloroform to dissolve any adhering crystals, collect the chloroform in the tared flask or beaker containing the washed crystals, evaporate the solvent with the aid of a blast of air, dry the crystals at 60° C. (140° F.) for one-half hour and weigh. The resulting weight will be the amount of cantharidin obtained from ten grammes of Cantharides." *U. S.*

Dried Spanish flies preserve the form and color, and, to a certain extent, the disagreeable odor, of the living insect. They have an acrid, burning, and urinous taste. Their powder is of a grayish-brown color, interspersed with shining green particles, which are the fragments of the feet, head, and wing-cases. If kept perfectly dry, in well-stoppered glass bottles, they retain their activity for a great length of time. A portion which had been preserved by Van Swieten for thirty years, in a glass vessel, was found still to possess vesicating properties. But exposed to a damp air they quickly undergo putrefaction, and this change takes place more speedily in the powder. Hence the insects should either be kept whole, and powdered as they are wanted for use, or, if kept in powder, should be well dried immediately after pulverization, and preserved in air tight vessels. They should never be purchased in powder, as, independently of the consideration just mentioned, they may in this state be more easily adulterated. Davis (*Proc. Mich. Ph. Ass.*, 1910, p. 62) reports that when cantharis is subjected to a microscopical examination the presence of other kinds of beetles and insects may be detected. But, however carefully managed, cantharides are apt to be attacked by mites, which feed on the interior soft parts of the body, reducing them to powder, while the hard exterior parts are not affected. An idea was at one time prevalent that the vesicating property of the insect was not injured by the worm, which was supposed to devour only the inactive portion. But this has been proved to be a mistake. Farines, an apothecary of Perpignan, has satisfactorily shown that, though the hard parts left by these mites possess some vesicating power, and the powder produced by them still more, yet the sound flies are much stronger than either. Camphor, which has been recommended as a preservative, does not prevent the destructive agency of the worm. It appears from the experiments of Nivet that, though camphor does not preserve the entire fly from the attacks of the larvæ of the *Anthrenus*, it actually destroys the mites of the Cantharis so often found in the powder, and may, therefore, be introduced with advantage, in small lumps, into bottles containing powdered cantharides. (*J. P. C.*, xix, 604.) Ammonium carbonate has also been recommended as a preservative. Pereira has found that a few drops of strong acetic acid, added to the flies, are very effectual. Among the best means of preserving them, whether whole or in powder, is the application of the process of Apert, which consists in exposing them for half an hour, confined in glass bottles, to the heat of boiling water, which destroys the eggs of the insect, without impairing the virtues of the flies. (*J. P. C.*, xxii, 246.) Of course, the access of water to the flies should be carefully avoided. Lutrand recommends chloroform as the best preservative that he has tried. (*J. P. C.*, xviii, 214.) The U. S. Pharmacopœia directs the use of chloroform or carbon tetrachloride and either of these are among the simplest, safest and best preservatives to prevent the development of insects in drugs. It is stated by Farines that when the flies are destroyed by the vapor of pyroligneous acid, instead of common vinegar, they acquire an odor which contributes to their preservation. Cantharides will bear a very considerable heat without losing the brilliant color of their elytra; nor is this color extracted by water, alcohol, ether, or the oils, so that the powder might be deprived of all its active principle and yet retain the exterior characters unaltered. The wing-cases resist putrefaction for a long time, and the shining particles have been detected in the human stomach months after interment.

So early as 1778, Thouvenel attempted to analyze cantharides, and the attempt was re-

peated by Beaupoil in 1803; but no very interesting or valuable result was obtained until 1810, when Robiquet discovered in them a crystalline substance, which proved to be the vesicating principle of the insect and received the name of *cantharidin*. The constituents, according to Robiquet, are (1) a green oil, insoluble in water, soluble in alcohol, and inert as a vesicatory; (2) a black matter, soluble in water, insoluble in alcohol, and inert; (3) a yellow viscid matter, soluble in water and alcohol, and without vesicating powers; (4) cantharidin; (5) a fatty matter, insoluble in alcohol; (6) calcium and magnesium phosphates, acetic acid, and, in the fresh insect, a small quantity of uric acid. Orfila afterwards discovered a volatile principle, upon which the fetid odor of the fly depends. It is separable by distillation with water. Dragendorff has found a volatile principle which acts on the system in the same manner as cantharidin. When powdered flies are moistened with water and distilled, the part which passes over, at or below 100° C. (212° F.), contains this principle. (*Chem. News*, May 31, 1867.) That the green coloring matter is chlorophyll seems to be shown by the experiments of Pocklington, who (*P. J.* [3], iii, p. 681) found that when cantharides was treated with alcohol, ether, and carbon disulphide, the solutions yielded absorption spectra agreeing with that of chlorophyll. Cantharidin exists in commercial cantharides to the extent of from 0.6 to 0.9 per cent. (See also *Ph. Centralh.*, 1901, 674.)

Adulterations.—These are not common. Occasionally other insects, or even beads, are added, purposely or through carelessness. These may be readily distinguished by their appearance. Flies exhausted of their cantharidin are sometimes substituted for the genuine drug. They are worthless, and are to be distinguished by their lack of substance and their yielding a nearly colorless ethereal tincture. Pereira states that powdered flies are sometimes adulterated with euphorbium. According to the researches of Fahnestock (*A. J. P.*, 1879, p. 298), age destroys the activity of the drug without of necessity impairing its physical appearance.

The percentage of cantharidin found in cantharides furnishes the best test of their virtues. Wm. Procter succeeded, by means of chloroform, in isolating cantharidin with great facility. He treated the flies with chloroform by percolation, displacing the last portion by means of alcohol, and allowing the resulting solution to evaporate spontaneously. Cantharidin is thus obtained in crystals mixed with the green oil, the greater portion of which may be removed by bibulous paper. The residuary crystals are dissolved in a mixture of ether and alcohol, which, by the spontaneous evaporation of the ether, yields the cantharidin nearly pure. Mortreux, having ascertained that the cantharidin is insoluble in carbon disulphide, proposed to use this fluid for removing the fatty matter associated with the cantharidin crystals obtained by the use of chloroform. He employed the same liquid in estimating the proportion of cantharidin, which he found to be about 20 centigrammes for 40 grammes of the flies, or half of one per cent. (*J. P. C.*, 3e sér., xlvi, 33, 1864.) Wittstein obtains it by digesting coarsely powdered flies repeatedly with water, straining through linen and expressing, allowing the liquid to settle for a day, separating the supernatant oil, adding a little wood charcoal, evaporating to dryness, treating the residue with ether so long as the solution affords a laminated substance on evaporation, evaporating the ethereal solution, treating the residue with cold alcohol of 80 per cent. for one day with frequent shaking, and finally drying the scales. (See *A. J. P.*, xxviii.) Williams has obtained it by means of benzene. (*Ibid.*, xxvi.) For a method of assaying cantharides and its official preparations by H. G. Greenish and Harold Wilson, see *P. J.*, 1898, 255, or *Am. Drug.*, 1898, 224.

Uses.—Internally administered, cantharides are a powerful irritant, with a peculiar direction to the urinary and genital organs. Genito-urinary irritation is ordinarily the first symptom produced by small doses of cantharides, and, if the dose has been large enough, it may amount to violent strangury, attended with excruciating pain, and the discharge of bloody urine. Toxic doses of Spanish fly produce obstinate and painful priapism, vomiting, bloody stools, severe pains in the whole abdominal region, excessive salivation with a fetid breath, hurried respiration, a hard and frequent pulse, burning thirst, exceeding difficulty of deglutition, sometimes a dread of liquids, frightful convulsions, tetanus, delirium, and death. Orfila has known twenty-four grains of the powder to prove fatal. Dissection reveals inflammation and ulceration of the mucous coat of the whole intestinal canal. According to Poumet, if the intestines be inflated, dried, cut into pieces, and examined in the sun between two pieces of glass, they will exhibit small shining yellow or green points, strongly contrasting with the matter around them. (*J. P. C.*, 3e sér., iii, 167.)

The poisonous effects are to be counteracted by the use of emetics, cathartics, and opiates by the stomach and rectum. From the experiments of Schroff it seems that oils somewhat accelerate the poisonous action, probably by dissolving the cantharidin. (See *A. J. P.*, xxviii, 365.) By experiments upon dogs, Thouery, a French apothecary, has satisfied himself that animal charcoal possesses a real antidotal power. (*J. P. C.*, 1858, p. 65.)

Cantharides have been long and beneficially used in medicine. Either these or other vesicating insects appear to have been given by Hippocrates in *dropsy* and *amenorrhea*, in the latter of which complaints, when properly prescribed, they are a highly valuable remedy.

They are also useful in obstinate *gleet, leucorrhea,* and *seminal weakness,* and in *paralytic incontinence of urine.* They are used also in certain cutaneous eruptions, especially those of a scaly character, and in chronic *eczema.* Their unpleasant effects upon the urinary passages are best obviated by the free use of diluent drinks, or when severe, by opiate enemata.

Externally applied, cantharides excite inflammation in the skin, which terminates in a copious secretion of serum under the cuticle. It may be employed either as a rubefacient, or to blister. In the former capacity it is seldom used, but as an epispastic it is preferred to all other substances. When blisters are allowed to stay on only long enough to irritate the skin, but not to blister, they are known as *flying blisters.* Used in this way, they are sometimes of service in *neuralgias,* applied directly over the seat of pain. Their chief value is, however, found in cases of severe internal irritation. It is of great importance that the practitioner should clearly comprehend the distinct uses of the rubefacient and the blister. The rubefacient is to be employed as a revulsive when the internal irritation is severe but is not connected with pronounced organic change. The immediate impression of a rubefacient, acting as it does upon a much larger surface than does the blister, is greater than that of the blister, but the permanent revulsive action is much less. The blister is, therefore, to be used when the internal disease is connected with inflammatory structural change. Thus, in a case of *gastrodynia,* a rubefacient is of much more service than a blister, while the blister is decidedly more effective in *peritonitis.* In a general wide-spread *congestion of the lung* the rubefacient is to be preferred to the blister, but in *pneumonia* the blister to the rubefacient. As, however, congestion of neighboring parts usually accompanies a localized inflammation, a rubefacient is sometimes to be employed as a temporary substitute for or adjuvant to a blister. The amount of serous discharge produced by blisters appears to be sometimes of service in almost directly evacuating local serous exudations. Thus, not rarely, repeated blistering affords the best treatment of a *serous pleurisy.* Possibly, however, even in these cases, the blister acts purely as a counter-irritant, as it certainly does in *chronic rheumatism* and *neuritis.* In all *chronic joint inflammations* the best results may often be obtained by a reblistering, extending, if necessary, over weeks and months. In some cases of *skin disease* blisters are capable of substituting their own action for the original morbid disease, and they are still occasionally used for this purpose in *tinea capitis,* obstinate *herpes,* and other affections. The length of time that a blister should be applied varies with the individual and with the position of the disease. In some constitutions they produce a poisonous impression, attended with frequent pulse, dryness of the mouth, subsultus tendinum, and even convulsion. Such symptoms are probably the results of an intense peripheral nervous irritation acting upon very susceptible centers. Such is not, however, the case with the strangury which may follow absorption of the cantharidin, and which is always the result of the direct action of the cantharidin upon the genito-urinary tract. In order to avoid such genito-urinary irritation, and also as much as possible the pain at the seat of application, the blister should be left on only until it distinctly reddens the skin, when a flaxseed poultice may be applied, and in the course of two or three hours the blister is formed. The time necessary for such reddening of the skin is usually from four to six hours, if the cantharides be active. (See *Ceratum Cantharidis.*)

The dose of cantharides is one-half to one grain (0.032–0.065 Gm.) of the powder, which may be given twice a day, in the form of a pill, but it is rarely used internally. The tincture, however, is more frequently employed.

CAPSICUM. U. S. (Br.)

CAPSICUM Capsic. [Cayenne Pepper, African Chillies]

(kăp'sĭ-cŭm)

"The dried ripe fruits of *Capsicum frutescens* Linné (Fam. *Solanaceæ*), without the presence or admixture of more than 2 per cent. of stems, calyxes or other foreign matter." *U. S.* "Capsicum is the dried ripe fruit of Capsicum minimum, *Roxb.*" *Br.*

Capsici Fructus, *Br.;* Piper Hispanicum; Capsicum Fruit, African or Pod Pepper, Red Pepper, Chillies, Bird Pepper, Spur Pepper; Fructus Capsici, *P. G.;* Spanischer Pfeffer, Schlotenpfeffer, *G.;* Piment de Cayenne, Piment des Jardins, Poivre d' Espagne, Poivre de Guinée, Poivre d'Inde, Poivre de Cayenne, Piment rouge, Capcique, *Fr.;* Peperone, *It.;* Pimiento, Chile, Aji, *Sp.*

Owing probably to its widespread cultivation, the genus Capsicum contains a large number of plant forms whose specific relations afford a very difficult problem to the systematic botanist. The probability is that the entire genus was originally confined to the American tropics, although it has been cultivated since the time of Columbus in the temperate and tropical zones of almost the whole world. Its first appearance in literature seems to be in an epistle by Peter Martyn, dated September, 1493, speaking of its having been brought by Columbus. Neither in ancient Sanscrit, Chinese, Greek, Latin, or Hebrew is there a name for it. In 1887 Asa Gray expressed his belief that there are only two species in the genus, although in the last previous revision of the genus, in 1852, Dunal had recorded fifty species. After a very thorough and careful study of the subject, including the cultivation of every procurable va-

riety and species for four years in the Missouri Botanical Garden, H. C. Irish has reached the conclusion that the dictum of Gray was correct, and that there are really only two species of the genus, one of which is herbaceous and annual or biennial, the other shrubby and perennial, a conclusion which seems to be accepted.

The first of these species is the one most extensively cultivated in Europe and in this country; it is the *C. annuum* L. The second is in its varieties very largely grown in the tropical and subtropical latitudes, its fruit not ripening at all or only to a slight degree in the temperate zone. It is the species which was described under the name of *C. frutescens*, by Linnæus, in 1737. By Irish it is divided into two varieties—*C. frutescens* proper, which is characterized by its fruit being oblong, acuminate, and usually embraced by the calyx, and *C. frutescens baccatum*, which is characterized by its ovate or subround fruit, usually seated on the calyx. This variety is the *C. baccatum* of Linnæus, 1767. In the first of these varieties are comprised the *C. fastigiatum* of Blume and the *C. minimum* of Miller and of Roxburgh, which yield most of the Cayenne pepper produced in the tropics, although, especially in the West Indies and South America, *C. baccatum* is largely cultivated. It is even doubtful whether *C. annuum* should be considered as a distinct species from *C. frutescens*, as in tropical climates varieties have been produced which are perennial and somewhat woody.

The British Pharmacopœia seems to be in error in ascribing the original description of the *Capsicum minimum* to Roxburgh, since his *Flora Indica* did not appear until 1832, whereas the species was described by Miller, in the *Garden Dictionary*, in 1771.

The following are the characteristics of *C. frutescens*, the shrubby capsicum, as given by Irish: "Plants shrubby, perennial, two and a half to six feet high. Branches angular, often channelled, puberulent or pubescent, especially on the younger portions; usually greatly enlarged and slightly purple at the nodes, green or sometimes purplish striate. Leaves broadly ovate, acuminate, 7.5 to 15 cm. long, usually puffed or wrinkled, more or less pubescent, especially around the veins. Petioles medium, usually subciliate; peduncles slender, 2.5 to 5 cm. long, often in pairs, usually longer than the fruit. Calyx usually cup-shaped, embracing base of the fruit; teeth short, corolla white or greenish white, spreading 10 to 20 mm. long, often with ocherous markings in the throat. Fruit red, ovate, obtuse or oblong acuminate, 20 to 30 mm. long and 6 to 18 mm. in diameter."

Capsicum annuum is largely cultivated both in the United States and in Europe, flowering in the early or middle summer, and ripening its fruit in the early autumn. There are numerous varieties of it differing in the shape of their fruit. That which is chiefly cultivated in the United States for market, to be used in the green state in pickling, or cooked for the table, is a large irregularly ovate or conical berry, depressed or horned at the extremity, and when ripe varying in color from yellowish to scarlet. A variety with a long, conical, pointed and recurved fruit, which is usually not thicker than the finger, is said to be especially used in the making of red pepper. In another variety the berries are not more than an inch in diameter, spherical and slightly compressed.

When ground into powder the fruit of the *Capsicum annuum* constitutes *paprika*, or as it is sometimes called, *sweet pepper;* it is very little used by itself but is largely employed for the mixing with the powder of chillies or true cayenne pepper; it has scarcely more than one-sixth the pungency of real cayenne pepper, so that the addition of it to powdered chillies may almost be considered an adulteration.

Paprika or *Hungarian Pepper* is recognized by the German Pharmacopœia. It is usually imported into the United States in a ground condition, three grades being recognized. 1. *Rosén-paprika* or *Rozsapaprika*, the best grade possesses a beautiful red color and has a savory taste. It is prepared from the selected pericarp and seeds which are carefully washed before being ground, the stems and placentæ being removed. 2. *Königs-paprika* or *Kiralypaprika* is prepared by grinding the entire pods, including not only the seeds but the stems. 3. *Mercantil-paprika* is prepared from the spotted pods, remaining from the selection for the finer grades, and from the pods containing flaws and also contains the stems, seeds and other parts. The last grade has a pale yellow color and is much more pungent. (Tolman and Mitchell, *Bull. No. 163, Bureau of Chemistry, U. S. Dept. of Agriculture.*) The cayenne pepper of the grocery stores is very largely a mixture of paprika and true pepper. The microscopic characteristics in the fruits of the two species are not sufficiently pronounced to be of avail in detecting the presence of the feebler substance in the powdered pepper, although, according to T. Edward Wallis, the outer portions of the pericarp of *Capsicum annuum* are cuticularized or suberized, while in *Capsicum fastigiatum* all the cells are composed purely of cellulose. True cayenne pepper, *chillies* or *bird pepper*, is produced in almost all tropical and subtropical countries, but is said to come in very large proportion from Zanzibar. The pod is at once distinguished by the peculiar thinness and tendency to wrinkle of its outer coating.

The varieties of cayenne pepper are numerous as they occur in the American market—the pods of the *East African pepper* are about 12 mm. in length, flattened, almost cylindrical, although showing distinctly the conical form; the pods of the *Madagascar peppers* reach the length of 6 to 7 cm. and a breadth of about 20 mm.; those of the *Bombay* or *cherry pepper* are very dark in color, 3.5 to 5 cm. in length,

and 12 mm. or more in breadth at the base. They are strictly conical and less likely to be flat than those of the other varieties. *Zanzibar pepper* is smaller than the *East African pepper* but otherwise similar to it. *Japanese capsicum*, whose botanical source is not positively known, occurs in the market in two forms, one in which the pods are large, reaching the length of about 6 cm.; the other in which the small pods are not 2.5 cm. in length. The larger pods are scarcely to be distinguished from *Madras chillies;* the smaller resemble, but are nearly twice the size of, the East African pepper. The color of the pods varies from light yellowish-brown to deep red.

about twelve to twenty millimetres in length and about six millimetres in diameter; sometimes attached to a five-toothed inferior calyx, and long, straight, slender peduncle. Pericarp somewhat shrivelled, glabrous, translucent and leathery, containing from ten to twenty small flat seeds, either loose or attached to a thin reddish dissepiment. The cells of the outer epidermis of the pericarp have moderately thick walls, are often arranged in rows of five to seven, and exhibit a cuticle uniformly striated (distinction from the fruits of other species of Capsicum). Characteristic odor; taste intensely pungent. Ash not more than 7 per cent." *Br.*

T. Edward Wallis believes that the different cayenne peppers can be distinguished from one another when powdered by the character of their epidermis and the tissue immediately below it, and gives the following tabulated summary of the differences. (*P. J.*, July, 1902.)

	C. minimum.	*C. annuum.*	*Japanese Chillies.*
Epidermis.	Thick and straight-walled rectangular cells with few pits; often arranged in groups of five to seven in a row and with a uniformly striated cuticle. Size of cells, 25 mkm. to 60 mkm. in either direction.	Irregular polygonal cells with evenly thickened walls, traversed by numerous well-marked, simple pits. The cuticle shows striated ridges. Size of cells, 60 mkm. to 100 mkm. long, and 25 mkm. to 50 mkm. wide.	Cells with strongly thickened walls and a radiated lumen. The pits only rarely penetrate the whole thickness of the wall. No visible striation. Size of cells, 30 mkm. to 80 mkm. long, and 15 mkm. to 45 mkm. wide.
Hypodermis.	Delicate thin-walled cellulose cells.	Several layers of cuticularized collenchymatous cells, having a rounded outline and very few pits.	A single layer of regular polygonal cells with cuticularized, fairly thick walls, traversed with numerous pits, which give them a beaded appearance.

The U. S. Pharm. describes the fruit of *C. frutescens* as follows: "Oblong-conical, from 8 to 20 mm. in length and from 2 to 15 mm. in diameter; pericarp brownish-red or orange, shining, membranous and translucent; 2- or 3-locular, united below, and containing 6 to 17 flat, reniform, yellowish seeds attached to the placenta or frequently separated from it; odor characteristic, sternutatory; taste intensely pungent. The calyx, when present, light greenish-brown, inferior, inconspicuous, 5-toothed, usually attached to a long straight peduncle. The powder is yellowish-brown; mounts made with hydrated chloral T.S. and examined under the microscope show yellowish-red oil globules; stone cells of two kinds, those of the endocarp being more or less elongated, walls yellowish, uniformly and moderately thickened, wavy in outline, porous and slightly lignified, those of the seed-coat being yellowish, irregular and strongly thickened, wavy in outline and strongly lignified. Capsicum yields not less than 15 per cent. of non-volatile extractive, soluble in ether (see Part III, Test No. 13). Capsicum yields not more than 7 per cent. of ash. The amount of ash, insoluble in hydrochloric acid, does not exceed 1 per cent. of the weight of Capsicum taken." *U. S.*

The Br. Pharm. gives the characteristics of the fruit of *C. minimum* as "Dull orange-red, oblong-conical, obtuse, two-celled fruits, from

The difficulty of distinguishing the source of powdered capsicum is increased by the fact that the red color fades upon exposure to light, and that the powdered African pepper, though very powerful, is a light brownish-yellow. The value of any specimen may be, however, fairly estimated by the intensity of its odor, which is peculiar, somewhat aromatic, and extremely irritant, and by its acrid, burning taste. The pungency appears to depend on a peculiar principle, which was obtained, though not in a perfectly isolated state, by Braconnot, and named *capsicin*. It is obtained as a thick yellowish-red liquid, but slightly soluble in water. When gently heated it becomes very fluid, and at a higher temperature is dissipated in fumes which are extremely irritating if inhaled. Capsicin is a mixed substance, consisting of resinous and fatty matters. In 1876, Thresh isolated a well defined active principle, *capsaicin*, from the extract which he obtained by exhausting Cayenne pepper with petroleum. From the red liquor dilute caustic alkali removes capsaicin, which is to be precipitated in minute crystals by passing carbon dioxide through the alkaline solution. The crystals may be purified by recrystallizing them from either alcohol, ether, petroleum benzin, glacial acetic acid, or hot carbon disulphide; in petroleum, capsaicin is but sparingly soluble, yet it is dissolved abundantly on the addition of fatty oil. The

crystals of capsaicin are colorless, and answer to the formula $C_9H_{14}O_2$; they melt at 59° C. (138.2° F.), and begin to volatilize at 115° C. (239° F.), but decomposition can be avoided only with great care. The vapors of capsaicin are of the most dreadful acridity, and even the ordinary manipulation of that substance requires much precaution. Felletar (*J. P. C.*, April, 1870, p. 347) first obtained from capsicum fruits a volatile alkaloid, which resembles coniine in odor, but is distinguished by the different shape of its hydrochloride crystals. H. Pabst (1892) made a thorough investigation of the fruit of *C. annuum*. He does not think that an alkaloid exists originally in the fruit, but believes that the alkaloidal reactions are due to a decomposition product. He finds, besides capsaicin, a red coloring matter, and oleic, palmitic, and stearic acids. The red coloring matter, by saponification, was shown to be a cholesterin ester of the fatty acids. (*A. J. P.*, 1892, 370.) Moerbitz (1898) isolated a pungent principle having a bitter taste, which he states is neither capsicin nor capsicol, and names *capsicutin*. He gives it the formula $C_{35}H_{54}N_3O_4$, and states that it is neither an alkaloid nor glucoside; it does not have acid properties. Red lead oxide is sometimes added to the powdered capsicum sold in Europe; it may be detected by digestion in diluted nitric acid, and precipitating the lead by sodium sulphate. Capsicum is said to be sometimes adulterated with colored sawdust, which may be recognized by the microscope. It is often adulterated with inert vegetable substances. The British Pharmacopœia requires that capsicum should yield on incineration not more than 6 per cent. of ash; this test would detect the presence of most adulterants. It is occasionally attacked by insects.

Uses.—Capsicum is a very powerful local stimulant, producing, when swallowed, a sense of heat in the stomach, and a general glow over the body without any narcotic effect. It is much employed as a condiment, especially in hot climates, and is useful in cases of *atony of the stomach* or *intestines*. It is strongly contraindicated by the existence of gastric catarrh of the ordinary type, but in the chronically inflamed stomachs of persons of intemperate habits it frequently appears to do good, probably by lessening the size of the dilated blood vessels and thereby relieving chronic congestion. It is often added with advantage to tonic prescriptions in cases of *neurasthenia*.

Applied externally, Cayenne pepper is a powerful rubefacient, which has the advantage of acting speedily without danger of producing vesication. It may be applied in the form of cataplasm, or more conveniently and efficiently as a liniment. It may be used in strengths of from 10 to 20 per cent. mixed either with alcohol or cotton-seed oil. The powder or tincture brought into contact with a *relaxed uvula* often acts very beneficially. The tincture has also been used advantageously in *chilblain*. The fluidextract and the oleoresin (*Oleoresina Capsici, U. S.*) are powerfully rubefacient. A gargle may be prepared by infusing half a drachm of the powder in a pint of boiling water, or by adding half a fluidounce of the tincture to eight fluidounces of rose water.

Dose, of the powder, from one to ten grains (0.065 to 0.65 Gm.), which is most conveniently given in the form of pill. Of an infusion prepared by adding two drachms to half a pint of boiling water, the dose is half a fluidounce (15 mils).

CARBO

CARBON

(cär-bō)

C = 12.

Carbone, *Fr.;* Kohlenstoff, *G.;* Carbone, *It.;* Carbon, *Sp.*

Carbon is an element of great importance, and very extensively diffused in nature. It exists in large quantity in the mineral kingdom, and is the most abundant constituent of animal and vegetable matter. In the crystallized state it constitutes the diamond; and, more or less pure, it forms the substances called *graphite* (or black lead and *plumbago*), anthracite and bituminous coal, coke, animal charcoal, and vegetable charcoal. Combined with oxygen it forms carbon dioxide, or carbonic acid gas, which is a constituent of the atmosphere, and present in many natural waters, especially those which have an effervescing quality. United with oxygen and a base it forms the carbonates, among others calcium carbonate, which is one of the most abundant minerals. There are three allotropic conditions of carbon, represented respectively by the diamond, graphite, and charcoal.

The *diamond* has been found in quantity in India, in Brazil, and in South Africa, but at the present time is obtained almost exclusively from the last named locality. Several diamonds have been found in the gold regions of Georgia and North Carolina. This gem is perfectly transparent, and the hardest and most brilliant substance in nature. Its sp. gr. is about 3.5. It is fixed and unalterable in the fire, provided air be excluded, but is combustible in air or oxygen, the product being the same as when charcoal is burned, namely, carbon dioxide. It has been made artificially at the temperature of the electric arc (2500° to 3000° C.) by Moissan.

Next to diamond, *graphite* or *plumbago* is the purest natural form of carbon. Graphite is the substance of which black-lead crucibles and pencils are made. It is found in greatest purity in the mine of Borrowdale, in England, and in Ceylon, from which latter place most of the graphite of commerce is now obtained, but it also occurs very pure in this country, and in deposits at Ticonderoga, N. Y., at Stourbridge, Mass., and in Canada and Brazil. In physical characters it is utterly different from the diamond; it crystallizes in hexagonal plates, is very soft and unctuous, of 2 to 2.5 sp. gr., and generally contains a little ash. In connection with the production of silicon carbide (carborundum) in the electric furnace, Acheson has produced a very pure artificial graphite by simply increasing the heat until the silicon was volatilized. This artificial graphite has a specific gravity of 2.5, is soft and of high metallic lustre. It is extensively used for electrodes in the electrolysis of brine and similar operations, and for graphite paint.

Anthracite, the purest variety of natural coal, occurs in different parts of the world, but particularly in the State of Pennsylvania. It contains from 90 to 95 per cent. of carbon, and several per cent. of ash. *Bituminous coal* is another variety, containing, besides the fixed or free carbon, some 10 to 15 per cent. of volatile hydrocarbons or gas-making material. When this is driven off by the process of charring, as in the manufacture of coal-gas, a kind of mineral charcoal, called *coke,* is obtained, very useful in the arts as a fuel. When peat is charred, it is converted into *peat charcoal,* which forms a cheap deodorizer, applicable to the purification of hospitals, dissecting-rooms, factories, privies, etc.

Carbon may be obtained in a state approaching to purity by several processes. One method is to expose lamp-black to a full red heat in a close vessel. It may also be obtained, in a very pure state, by passing the vapor of volatile oils through an ignited porcelain tube, whereby the hydrogen and oxygen of the oil will be dissipated, and the charcoal left in the tube. The purest lamp-black is now made from natural gas in Western Pennsylvania and in Ohio. This lamp-black is miscible with water, does not color ether, and is free from oily matter.

Colloidal carbon may be easily prepared by gradually adding 2 Gm. of sugar to 20 Gm. of sulphuric acid with continuous agitation and then pouring the mixture into 80 mils of water and filtering. The sulphuric acid may be removed by dialysis and a clear black solution of colloidal carbon remains.

Properties.—Carbon, in its uncrystallized state, is an insoluble, infusible solid, generally of a black color, and without taste or odor. It burns when sufficiently heated, uniting with the oxygen of the air, and generating carbon dioxide. Its sp. gr. in the solid state, apart from its pores when in mass, is 3.5; but with the air of the pores included, it is only 0.44. It is an almost unalterable and indestructible substance, and has great power in resisting and correcting putrefaction in other bodies. When properly prepared, it possesses the property of absorbing the coloring and odorous principles of most liquids. See (*Carbo Animalis.*) Its other physical properties differ according to its source and peculiar state of aggregation. As a chemical element it enjoys a very extensive range of combination. It forms two compounds with oxygen, *carbon dioxide* (carbonic acid gas) and *carbon monoxide* (carbonous oxide). With hydrogen it forms a number of compounds, called *hydrocarbons,* of which the most interesting are light carburetted hydrogen or marsh-gas, olefiant gas, acetylene, the hydrocarbons constituting petroleum, coal tar hydrocarbons, as benzol, and naphthalene, and some essential oils. With nitrogen, carbon constitutes cyanogen, the compound radical of hydrocyanic or prussic acid, and when united in minute proportion with iron as carbide it is present in cast iron and steel.

CARBO LIGNI. U. S., Br.

WOOD CHARCOAL Carbo. Lig. [Charcoal]

(cär'bō lig'nī)

"Charcoal prepared from soft wood, and very finely powdered. Preserve it in well-closed vessels." *U. S.* "Wood Charcoal is wood charred by exposure to a red heat without access of air." *Br.*

Carbo Præparatus, Carbo e Ligno, Carbo Vegetabilis; Wood Charcoal, Vegetable Charcoal; Charbon Végétal, Charbon de bois, *Fr.;* Carbo Ligni Pulveratus, *P. G.;* Gepulverte Holzkohle, Holzkohle, Präparirte Kohle, *G.;* Carbone Vegetale, Carbone di legno, *It.;* Carbon vegetal medicinal, Carbon de lena, *Sp.*

Preparation on the Large Scale.—Billets of wood are piled in a conical form, and covered with earth and sod to prevent the free access of air, several holes being left at the bottom and one at the top of the pile, in order to produce a draught to commence the combustion. The wood is then kindled from the bottom. In a little while the hole at the top is closed, and, after the ignition is found to have pervaded the whole pile, those at the bottom are stopped also. The combustion taking place with a smothered flame, the volatile portions of the wood, consisting of hydrogen and oxygen, are dissipated, while the carbon is left, a portion of it, however, being lost by combustion. Wood, thus carbonized, yields not more than 17 or 18 per cent. of charcoal. A better method is to char the wood in iron cylinders, when it yields from 22 to 23 parts in 100 of excellent charcoal; and, at the same time, the means are afforded for collecting the volatile products, consisting of pyroligneous acid, empyreumatic oil, and tar. This process for obtaining charcoal has been described under another head. (See *Acidum Aceticum.*) A method of preparing charcoal by subjecting wood to super-

heated steam has been invented by Violette. When the temperature of steam is 300° C. (572° F.), the wood is converted into a peculiar charcoal, called *red charcoal,* which is intermediate in its qualities between wood and ordinary charcoal. When the temperature is lower, the carbonization is incomplete; when higher, the product is black charcoal. The steam process yields a uniform charcoal for a given temperature, which may be easily regulated, and a product about double that obtained in closed cylinders. Charcoal contains *carbon,* approximately in proportion to the temperature at which it is formed; varying from 65 per cent. when made at 250° C. (482° F.) to 80 per cent. when made at 400° C. (752° F.). The gaseous matter present, on the other hand, decreases with the temperature of carbonization. Thus, for charcoal made at 300° C. (572° F.), it is one-third of its weight; at 350° C. (662° F.), one-fourth.

E. C. C. Stanford has called attention to a variety of vegetable charcoal, obtained by charring a species of sea weed, *Laminaria digitata,* gathered on the shores of the Hebrides, which, on account of the large proportion of calcium carbonate contained in it (20 per cent.), is unfit for use in refining sugar; it, however, possesses more of the deodorizing and decolorizing power than animal charcoal itself, which, with the exception referred to, it closely resembles in chemical composition.

Preparation for Medicinal Use.—Belloc recommends charcoal for this purpose to be obtained from poplar shoots, cut at the time the sap rises, and deprived of their bark. The carbonization should be performed in cast iron vessels at a red-white heat. The product is a light and brilliant charcoal, which must be purified by being macerated for three or four days in water, frequently renewed. It is then dried, powdered, and placed in bottles, which should be well-stoppered. The charcoal made from willow is generally preferred, although that obtained from maple is also largely employed. A fine charcoal is also made in Europe from the linden and poplar. The charcoal most esteemed in Philadelphia for medicinal purposes is that prepared by Dupont, near Wilmington, Delaware, for the manufacture of gunpowder; it is made from young willow shoots of two or three years' growth.

Properties.—Charcoal is a black, shining, brittle, porous substance, tasteless and inodorous, and insoluble in water. It is a good conductor of electricity, but a bad one of heat. It possesses the remarkable property of absorbing many times its own bulk of certain gases. "Wood charcoal is a black, odorless, and tasteless powder, free from gritty matter. It burns without a luminous flame. Incinerate about 1 Gm. of Charcoal; not more than 7.5 per cent. of ash remains. Boil about 1 Gm. of Charcoal with a mixture of 3 mils of potassium hydroxide T.S. and 10 mils of distilled water for one-half minute; the filtrate shows only a slight brown color." *U. S.*

The British Pharmacopœia describes it as "A black powder without odor or taste, free from gritty matter. When 1 gramme of the Charcoal is boiled for a few minutes with 5 millilitres of *solution of sodium hydroxide* diluted with 15 millilitres of *water* and the mixture filtered, the color of the filtrate is not deeper than pale yellow (absence of insufficiently carbonised wood). Ash not more than 7.5 per cent." *Br.*

When exposed to the air after ignition, charcoal increases rapidly in weight, absorbing from 12 to 14 per cent. of moisture. As ordinarily prepared, it contains the incombustible part of the wood, amounting to 1 or 2 per cent., which is left as ashes when the charcoal is burned. This inorganic material may be removed by digesting the charcoal in diluted hydrochloric acid, and afterwards washing it thoroughly with boiling water. Havenhill examined the wood charcoal of the western markets and found the ash to vary from 0.62 to 16.80 per cent. (*D. C.* 1914, p. 260.) Gane states that imperfectly carbonized samples are of frequent occurrence (*J. A. Ph. A.* 1912, p. 375). Knecht claims that the more closely the substance approaches in composition to pure carbon the less is its decolorizing power. (*Proc. VIIth Internat. Congress App. Chem.,* Sec. IVb., Coloring, 1909, London, 1910, pp. 17, 18.)

For internal use charcoal is preferred by some in the *granular form.* W. Lascelles Scott employs the following method of preparing it. He prefers the wood of the box, willow, or linden, which, after being charred, should be allowed to cool out of contact with air, then boiled for some time in diluted hydrochloric acid, and afterwards, having been thoroughly washed with pure water, in a little weak ammonia. The fragments are again ignited, and then quickly powdered, and passed through a sieve of 80 or 100 apertures to the inch. Nine pounds of this powder are mixed with one pound of pure sugar passed through a 30 sieve, and 4 ounces of gum arabic in impalpable powder. The whole is then moistened with a few ounces of warm distilled water, to which have been added an ounce and a quarter of tincture of benzoin, and a little mucilage. The mass is now granulated on flat steam pans, in the usual manner, at a temperature of 101.6° to 107.2° C. (215° to 225° F.). When perfectly dry it is sifted, and secured in well-stoppered bottles. (*Chem. News,* 1867, p. 204.)

Stenhouse has devised a process for combining alumina with common vegetable charcoal, forming what he calls *aluminized charcoal,* which is an economical substitute for purified animal charcoal, and equally efficacious as a decolorizer. It is prepared by digesting finely powdered charcoal with sufficient of the solution of aluminum sulphate to give an impregnation of 7.5 per cent. of alumina. The whole is evaporated to dryness, and ignited in a covered

Hessian crucible, until the water and acid have been dissipated. Aluminized charcoal is perfectly black, though thoroughly impregnated with anhydrous alumina, and only requires to be carefully pulverized to be ready for use. On similar principles, Stenhouse prepares his *artificial bone black,* by impregnating powdered wood charcoal with 7.5 per cent. of calcium phosphate, by digesting it in a solution of this salt in hydrochloric acid, evaporating to dryness, and igniting in covered vessels. This charcoal decolorizes well, but can be used only for neutral solutions.

Uses.—Charcoal is used in medicine chiefly for its absorbent properties, thus it is used locally in *gangrene* and *foul ulcers* to absorb the putrid gases. Internally it has been used in *meteorism* and *fermentative dyspepsia* with the idea of absorbing the gas. In many cases of *dyspepsia,* however, it appears to have some further action than that of a mere absorbent. As is well known, charcoal is capable of absorbing not only coloring matter but many other organic substances and it has been lauded by Kraus and Barbara (*D. M. W.,* 1915, xli) as an absorbent for toxins. For this action they recommend it internally in the treatment of *diarrhea* and *dysentery* and locally for various infected *wounds;* see also Eisner. (*Ther. Geg.* lvi.)

At one time it was much used as a dressing for ulcers but is at present rarely employed, though the *Cataplasma Carbonis* or charcoal poultice is still occasionally prescribed in Great Britain. Several of its varieties are used as tooth powder. Those generally preferred are the charcoals of the cocoa-nut shell and of bread. It is said that charcoal proves useful in preserving the teeth by absorbing the acid sometimes morbidly present in the mucus of the mouth. The dose of charcoal varies from one to four teaspoonfuls (3.9 to 15.5 Gm.) or more. Daniel gave it in his case of constipation in doses of a teaspoonful (3.9 Gm.), repeated every half hour. *Charcoal biscuits* have been prepared, containing 15 or 20 per cent. of charcoal in fine powder, while *charcoal lozenges,* either of charcoal alone or associated with bismuth, have been employed with asserted good results in certain forms of gastric disturbances. Scoville states that charcoal is a good antidote for phenol poisoning. It acts by absorbing phenol and eliminating it through the intestines rather than through the kidneys. (*Bull. Pharm.,* 1913, p. 393.)

Dose, five to twenty grains (0.32 to 1.3 Gm.)

Off. Prep.—Trochisci Carbonis Ligni, *N.F.*

CARBON DISULPHIDUM. Br.

CARBON DISULPHIDE [Carbon Bisulphide]

(cär'bŏn dī-sŭl'phī-dŭm)

CS_2=76.14

"Carbon Disulphide, CS_2, may be obtained by combining carbon and sulphur at a high temperature, the product being subsequently condensed and purified." *Br.*

Carbonis Bisulphidum, *Br.,* 1898; Carbonii Bisulphidum; Carbon Bisulphide; Carbon Sulphide; Sulfure de Carbone, *Fr. Cod.;* Carboneum Sulfuratum, Alcohol Sulfuris, Schwefelkohlenstoff, Kohlensulfid, Schwefelalkohol, *G.;* Solfuro di carbonio, *It.;* Sulfuro de carbono, *Sp.*

This compound, corresponding to carbon dioxide (carbonic acid gas), CO_2, is prepared by the direct combination of carbon and sulphur at a moderate red heat. To effect this, charcoal is heated to redness in a vertical cylinder, while sulphur is admitted through a lateral tubulure near the bottom. As the sulphur melts and vaporizes, it combines with the carbon, and the carbon disulphide formed distils over through a series of condensing tubes, which, while they serve to collect the crude carbon disulphide, allow of the escape of the hydrogen sulphide formed at the same time. The crude product is then rectified, first over a solution of chlorinated lime to break up any hydrogen sulphide gas remaining, and then repeatedly either over mercury, mercuric chloride, anhydrous cupric sulphate, or over a pure fatty oil, which withdraws from it all free sulphur and malodorous sulphur compounds. The manufacture of carbon disulphide has assumed large proportions. In the works of Deiss at Pantin, near Marseilles, France, 5000 kilogrammes were turned out daily, and their annual production exceeds 1,200,000 kilogrammes.

The most decided improvement in the manufacture of carbon disulphide was made by E. R. Taylor of Penn Yan, New York, who introduced a patented electrothermal process which can be worked continuously. In large furnaces 41 feet high by 16 feet in diameter an alternating current is applied through carbon electrodes. The metallic sulphur passing over the electrodes is vaporized and rises through the glowing carbon, the carbon disulphide being taken off as vapor through a side connection near the top of the furnace. The impure carbon disulphide is purified by forcing lime water in a fine spray through the disulphide liquor until the water runs out of the tank colorless. The carbon disulphide is finally rectified by steam heat. It is used in the arts for the extraction of oils from different oil seeds, for the extraction of sulphur from some varieties of sulphur ores, for the cleansing of wool and recovering the fat, as a solvent for caoutchouc in the manufacture of india rubber goods, for the extraction of perfumes, and on an enormous scale in France as a remedy against the *phylloxera.* Von Lengyel describes a carbon sulphide having the composition C_3S_2. (*Proc. A. Ph. A.,* 1893, 1021.)

Properties.—Carbon disulphide is official in Part II of the U. S. P. IX and is described as follows: "Preserve in partially filled, well-stoppered bottles, or in tin cans, in a cool place, remote from flame or fire. A clear, colorless, highly refractive liquid, very volatile, having a strong, characteristic but not fetid odor, and a sharp, aromatic taste. Specific gravity between 1.256 and 1.257 at 25° C. (77° F.) Soluble in about 530 parts of water at 25° C.

(77° F.); very soluble in alcohol, ether, chloroform, or fixed or volatile oils. Carbon disulphide vaporizes rapidly at the ordinary temperature, is highly inflammable, boils between 46° and 49° C. (114.8°–120.2° F.), and when ignited, burns with a bluish-white flame, producing carbon dioxide and sulphur dioxide. It does not affect the color of blue litmus paper moistened with water (*sulphur dioxide*). Twenty mils when allowed to evaporate spontaneously in a glass dish and finally on a water bath leaves not more than 0.001 Gm. of residue (*dissolved sulphur*). No discoloration is produced in 10 mils of lead acetate T.S. after agitating with 25 mils of carbon disulphide, when viewed from above in a test tube of about 2 cm. in diameter (*hydrogen sulphide*)." *U. S.*

"A clear, colorless, highly refractive liquid. Odor characteristic but not fetid. Specific gravity 1.268 to 1.269. Highly inflammable, burning with a blue flame and giving off carbon dioxide and sulphur dioxide. Boiling point 46° to 47° C. (114.8°–116.6° F.). Vapor mixed with air is explosive in contact with flame. Evaporated spontaneously in a glass vessel, it leaves no residue (absence of free sulphur)." *Br.*

Uses.—Although carbon disulphide has been recommended by Taar (*B. Thier., W.*, 1907, p. 406) for the destruction of intestinal parasites in the horse, it has not found its way into human medicine as an internal remedy. It is, however, occasionally used externally as a counter-irritant and local anesthetic. Turnbull especially recommended it as an external application in *enlarged lymphatic glands*. He applied it by means of a bottle with a proper sized mouth, containing a fluidrachm of the disulphide, imbibed by a piece of sponge; the skin over the gland is first well moistened with water. He employed the vapor also with benefit in deafness, when dependent on want of nervous energy and a deficiency of wax. For this purpose, the bottle containing the disulphide is made with a neck to fit the meatus, and, being applied to the ear, is held there until considerable warmth is produced. The remedy has been used often with very good results, in a similar manner, in *facial* and other *neuralgias* and various local *pains*. It causes a good deal of smarting, but its disagreeable odor is the chief objection to it. In France the disulphide has been used in *diarrhea* in 3.5 per cent. solution, of which the dose is two tablespoonfuls (30 mils) four or five times a day.

Its most important use is as a solvent, especially for rubber. Carbon disulphide is an active poison and workmen exposed to the fumes of the disulphide are affected with headache, vertigo, and over-excitement of the nervous system, as evinced by voluble talking, incoherent singing, or immoderate laughter, or sometimes by weeping; and a continuance of the exposure is apt to finally cause a state of cachexia, characterized by general weakness, loss of sexual appetite, dullness of sight and hearing, and impairment of memory Later writers assert that these phenomena are hysterical, and that what the carbon disulphide does is to produce an hysterical neurosis. (See *Annales de Hygiène*, 1895, xxxiii.) The swallowing by a man of half an ounce of carbon disulphide was followed in half an hour by absolute unconsciousnes, very rapid, feeble pulse, slow and stertorous respiration, cold and clammy surface of body, and insensitive conjunctiva, with mobile pupils. Two hours later, death occurred. The blood was found fluid, but there were no marked lesions of irritation in the gastro-intestinal mucous membrane. (*L. L.*, July 17, 1886.) India rubber workers, by whom the disulphide is largely used, are said to suffer frequently from paralytic symptoms. (*L. L.*, Jan., 1886.)

CARDAMOMI SEMEN. U. S. (Br.)

CARDAMOM SEED Cardam. Sem. [Cardamomum U.S. VIII Cardamom]

(kär-da-mō'mī sē'mĕn)

"The dried seeds of *Elettaria Cardamomum* White et Maton (Fam. *Zingiberaceæ*), recently removed from the capsules." *U. S.* "Cardamom Seeds are the dried ripe seeds of Elettaria Cardamomum, *Maton*. The seeds should be kept in their pericarps and separated when required for use." *Br.*

Cardamomi Semina, *Br.;* Cardamomum Minus, Cardamomum Malabaricum; Malabar Cardamoms, Cardamoms; Cardamome du Malabar, *Fr. Cod.;* Petit Cardamome, *Fr.;* Fructus Cardamomi, *P. G.;* Malabar Kardamomen, Cardamomen, Kleine Kardamomen, *G.;* Cardamomo minore, *It.;* Cardamomo, Cardamomo menor, *Sp.;* Ebil, *Arab.;* Kakelah seghar, *Pers.;* Capalaga, *Malay;* Gujaratii elachi, *Hindost.*

The fruit of cardamom is official in most of the Pharmacopœias. The U. S. Pharmacopœia in its definition confines cardamom to the seeds. In this it follows the British Pharmacopœia which has always limited the drug to the seeds, but specifically states that the fruit should be kept intact and the seeds separated when required for use. This step was probably a wise one as there has always been some confusion by manufacturers as to whether the article designated as cardamom is a formula was restricted to the seeds or not. On the other hand the pericarp contains some oil and forms an excellent surface for the grinding of the seeds. Furthermore, the decorticated seeds are liable to adulteration with seed of wild cardamom and other foreign seeds which are not detected except upon careful examination.

The subject of cardamom has been involved in some confusion and uncertainty, both in its commercial and botanical relations. The name has been applied to the aromatic capsules of various Indian plants belonging to the family of *Zingiberaceæ*. Three varieties have long been designated by the several titles of the *lesser, middle, and larger—cardamomum minus, me-*

dium, and *majus;* but these terms have been used differently by different writers, so that their precise signification remains doubtful. To Pereira we are mainly indebted for the clearing up of this confusion. It is well known that the *lesser cardamom* of most writers is the variety recognized by the Pharmacopœias and generally kept in the shops. The other varieties, though circulating to some extent in European and Indian commerce, are little known in this country.

Ceylon Cardamom.—This has been denominated variously *cardamomum majus* and *cardamomum longum,* and is sometimes termed in English commerce *wild cardamom.* It is the *large cardamom* of Guibourt. In the East it is sometimes called *grains of Paradise;* but it is not the product known with us by that name. (See below.) It is derived from a plant cultivated in Candy, in the Island of Ceylon, and also growing wild in the forests of the interior, which was designated by Sir James Edward Smith *Elettaria major,* but is now generally acknowledged to be only a variety of the official plant. (*Elettaria Cardamomum* var. *β-Major* Smith.) It is affirmed that the annual product reaches nearly 750,000 pounds. The fruit is a lanceolate-oblong, acutely triangular capsule, somewhat curved, about 3.5 cm. long and 6 to 8 mm. broad, with flat and ribbed sides, tough and coriaceous, brownish or yellow ash-colored, having frequently at one end the long, cylindrical, three-lobed calyx, and at the other the fruit-stalk. It is three-locular, and contains angular, rugged, yellowish-red seeds, of a peculiar fragrant odor and spicy taste. Its effects are analogous to those of the official cardamom.

Round or *Siam Cardamom.*—This is probably the *Αμωμον* of Dioscorides and the *Amomi uva* of Pliny, and is believed to be the fruit of *Amomum cardamomum,* Willd., growing in Sumatra, Java, and other East India islands. The capsules are usually smaller than a cherry, roundish or somewhat ovate, with three convex sides, more or less striated longitudinally, yellowish or brownish-white, and sometimes reddish, with brown, angular, cuneiform, shrivelled seeds, which have a spicy camphorous flavor. They are sometimes, though rarely, met with connected in their native clusters, constituting the *amomum racemosum,* or *amome en grappe,* of the French. They are similar in medicinal properties to the official, but are seldom used except in the southern parts of Europe.

Java Cardamom.—The plant producing this variety is supposed to be the *amomum maximum* of Roxburgh, growing in Java and other Malay islands in the East. The capsules are oval, or oval-oblong, often somewhat ovate, from 1.5 to 3 cm. long, and from 8 to 15 mm. broad, usually flattened on one side and convex on the other, sometimes curved, three-valved, and occasionally imperfectly three-lobed, of a dirty grayish-brown color, and coarse fibrous appearance. When soaked in water, they exhibit as their distinguishing character from nine to thirteen ragged membranous wings along their whole length. The seeds have a feebly aromatic taste and odor. This variety of cardamom affords but a very small proportion of volatile oil, is altogether of inferior quality, and, when imported into London, is usually sent to the continent.

Madagascar Cardamom.—This is the *Cardamomum majus* of Geiger and some others, and is thought to be the fruit of *Amomum angustifolium,* of Sonnerat, growing in marshy grounds in Madagascar. The capsule is ovate, pointed, flattened on one side, striated, with a broad circular scar at the bottom, surrounded by an elevated, notched, corrugated margin. The seeds have an aromatic flavor similar to that of official cardamom.

Bengal or *Nepal Cardamom.*—The fruit of *Amomum subulatum,* Roxb., sometimes known by the name of winged Bengal cardamom. *Morung elachi,* or *Buro elachi,* is about 2.5 cm. in length, obscurely three-sided, ovoid or somewhat obconic, with nine narrow, jagged ridges or wings (best seen after soaking in water) upon its distal end, which terminates in a truncate bristly nipple. The pericarp is coarsely striated, of a deep brown, splitting into three valves, disclosing a three-lobed mass of seeds, 60 to 80 in number.

Nepal Cardamom i. produced by an Amomum of undetermined species, and resembles the Bengal cardamom, except in having a long tubular calyx on its summit, and in being usually attached to a stalk.

Grains of Paradise. Grana Paradisi.—Under this name and that of *Guinea grains,* and *Melegueta* or *Mallaguetta pepper,* are found in commerce small seeds of a round or ovate form, often angular, and somewhat cuneiform, minutely rough, brown externally, white within, of a feebly aromatic odor when rubbed between the fingers, and of a strongly hot and peppery taste. Two kinds of them are known in the English market, one larger, plumper, and more warty, with a short conical projecting tuft of pale fibers on the umbilicus; the other smaller and smoother and without the fibrous tuft. The latter are the more common. It is probable that one of the varieties is produced by *Amomum Grana Paradisi* of Sir J. E. Smith, and the other by Roscoe's *Amomum Melegueta.* (Pereira's *Mat. Med.,* 3d ed., p. 1134.) W. F. Daniell, who has published (*P. J.,* xiv 312 and 356) an elaborate paper on the Amoma of Western Africa, states that the true Mallaguetta pepper is obtained exclusively from varieties of the same species to which belong the *Amomum Granum Paradisi* of Afzelius and the *A. Melegueta* of Roscoe; while the *A. Grana Paradisi* of Sir J. E. Smith is a different plant, and yields a different product. These grains are imported from Guinea, and other parts of the western coast of Africa. Similar grains are taken to England from Demerara, where they are ob-

tained from a plant cultivated by the negroes, supposed to have been brought from Africa, and believed by Pereira to be the *Amomum Melegueto* of Roscoe. (*P. J.*, vi, 412.) Their effects on the system are analogous to those of pepper; but they are seldom used except in veterinary practice, and to give artificial strength to spirits, wine, beer, and vinegar. Pereira points out seven distinct Scitamineous fruits to which the name of grains of Paradise has been applied by different authors. J. C. Thresh made a proximate analysis of the seeds, and found volatile oil, resin, tannin, starch, albuminoids, and an active principle in the form of a straw-colored viscid, odorless fluid, pungent, but not so hot as capsaicin. (*P. J.*, 1884, p. 297.) Fred'k Schwartz found in the seeds a reddish-brown acrid resin, and an oil having a burning aromatic taste, upon which the virtues probably depend. (*A. J. P.*, 1886, 118; consult also Hanausek's researches on grains of Paradise in *Chem. Ztg.*, 1893, 1765.)

Bastard Cardamom, the seeds of *Amomum Xanthioides* Wall., resembles true cardamom in appearance, but is of a dirty green color, and has a very biting camphor-like taste. B. Niederstadt gives the following as the results of analysis of the true (hulled) seed and of the bastard cardamom:

	True.	Bastard.
Water	15.25	15.50
Ether soluble extract	5.10	4.04
Ash	6.55	7.50
Starch and sugar	28.84	24.00
Cellular tissue, nitrogenous matters and extractive	44.26	48.96

A cardamom from East Africa, with a flavor resembling that of official cardamom and of the Korarima cardamom, is said to have been seen in the London market, but apparently has not been identified.

The official cardamoms are produced solely in India, chiefly in Malabar, Mysore, and adjacent regions. Malabar cardamoms are rather smaller than Mysore cardamoms.

The cardamom plant has a tuberous horizontal rhizome, sending up from eight to twenty erect, simple, smooth, green and shining, perennial stems, which rise from six to twelve feet in height, and bear alternate elliptical-lanceolate sheathing leaves. The flower-stalk proceeds from the base of the stem, and lies upon the ground, with the flowers arranged in a panicle. The fruit is a three-celled capsule, containing many seeds; during drying it is said to lose three-fourths of its weight.

This valuable plant is a native of the mountains of Indo-China, where it springs up spontaneously in the forests after the removal of the undergrowth, and is very extensively cultivated by the natives. Recent reports indicate that the cultivation of cardamom is being discontinued in favor of cinchona and rubber plantations on both the Malabar Coast as well as in Ceylon. For a detailed account of culture, see *A. J. P.*, 1877, 605; also *P. J.*, 1888, and *Bull. des Sc. Pharmacol.*, Paris, 1906, pp. 114 and 584. Cardamoms have also been cultivated to some extent in tropical America. The plant begins to yield fruit at the end of the fourth year, and continues to bear for several years afterwards. The capsules when ripe are picked from the fruit-stems, dried over a gentle fire or by sun-heat, and separated, by rubbing with the hands, from the footstalks and adhering calyces. J. W. Mollison describes the method of washing and curing cardamoms employed in the Bombay Presidency, India. The washing and manipulation is performed by women, and water from special wells is employed. The cardamoms are first washed in earthenware vessels containing a mixture of the well water with pounded soap nut and a species of acacia, in the proportion of two pounds of the former to a quarter pound of the latter. About ten pounds of cardamoms are treated at one time. Two women stir them vigorously in the mixture for about one minute and then allow them to rest about an equal length of time, and again stir for another minute. A thick lather results. This completes the first washing, after which the cardamoms are baled out by hand into a basket where they are allowed to drain for a few seconds, and then subjected to a second washing similar to the first except that the mixture contains less of the soap nut preparation and an additional quantity of soap solution. They are then thrown upon a mat and sprinkled with water from the special well at intervals of a half hour, until the next morning, when they are spread upon the roof of a house and allowed to dry for four or five hours. After nipping off the short stalk, an operation performed with a large pair of shears, the cardamoms are sorted, only the most plump fruits being prepared for the foreign market. Besides bleaching by this process, cardamoms are also subjected to starching in India. The starched product has a whiter appearance than the bleached cardamoms. The starch is prepared by pounding together rice, wheat, country soap and buttermilk. The paste is diluted with water and sprinkled over the cardamoms as they are rubbed by hand. (*B. C. D.*, 1904, see also *Ph. Era*, 1904, 137.) Most of the cardamom is sent to Bombay, from whence it is shipped to London, about 250,000 pounds being marketed annually. Thus prepared, they are ovate-oblong, from 10 to 17 mm. long, from 6 to 8 mm. thick, three-sided with rounded angles, obtusely pointed at both ends, longitudinally wrinkled, and of a yellowish-white color. The seeds constitute about 74 parts per cent. by weight. According to Pereira, three varieties are distinguished in commerce: 1, the *shorts*, from 6 to 12 mm. long, from 4 to 6 mm. broad,

browner and more coarsely ribbed and more highly esteemed than the others; 2, the *long-longs,* from 14 to 25 mm. in length by 4 to 6 mm. in breadth, elongated, and somewhat acuminate; and 3, the *short-longs,* which are somewhat shorter and less pointed than the second variety. The odor of cardamom is fragrant, the taste warm, slightly pungent, and highly aromatic.

"Mostly agglutinated in groups of from 2 to 7, the individual seeds, oblong-ovoid in outline, 3- or irregularly 4-sided, convex on the dorsal surface, strongly longitudinally grooved on one side, from 3 to 4 mm. in length; externally reddish-gray-brown, coarsely tuberculated, and with more or less adhering portions of the membranous aril; in section showing a thin reddish-brown seed-coat, a large white perisperm and a central, greenish endosperm enclosing a small straight embryo; odor aromatic; taste aromatic, pungent. The powder is greenish-brown; consisting chiefly of coarse angular fragments of cells of the reserve layers and seed-coat; cells of endosperm and perisperm filled with compound starch grains, the individual grains from 0.001 to 0.004 mm. in diameter; fragments of seed with dark brown stone cells, which are polygonal in surface view and about 0.02 mm. in diameter; in mounts made with hydrated chloral T.S. single prisms or crystals in rosette aggregates may separate in the cells of the endosperm and perisperm; fragments of spiral tracheæ with accompanying slightly lignified bast-fibers relatively few. Cardamom Seed yields not more than 8 per cent. of ash." *U.S.*

"Fruits from one to two centimetres long, ovoid or oblong, bluntly triangular in section, shortly beaked at the apex, pale buff in color, plump and nearly smooth or with slight longitudinal striations. Seeds dark reddish-brown, about three millimetres in length and the same in breadth and thickness, irregularly angular, transversely wrinkled, and enclosed in a thin, colorless, membranous aril. The powdered Seeds exhibit abundant, minute, angular starch grains, often compacted into masses; but no spiral vessels, sclerenchymatous fibres, or strongly elongated sclerenchymatous cells (absence of pericarps). Aromatic odor; taste agreeably warm and aromatic. Ash not more than 6 per cent." *Br.*

Cardamom yields its virtues to water and alcohol, but more readily to the latter. The seeds contain 4.6 per cent. of volatile oil, 10.4 of fixed oil, 2.5 of a salt of potassium mixed with a coloring principle, 3.0 of starch, 1.8 of nitrogenous mucilage, 0.4 of yellow coloring matter, and 77.3 of ligneous fiber. (Trommsdorff.) The volatile oil is colorless, of an agreeable and very penetrating odor, and of a strong aromatic, burning, camphorous, and bitterish taste. It is dextrogyrate, and consists essentially of a terpene, $C_{10}H_{16}$, with small quantities of formic and acetic acids. From old specimens of oil Dumas and Peligot claim to have separated crystals of *terpene hydrate,* $C_{10}H_{20}O_2 + H_2O$, while Flückiger has obtained a crystalline deposit from Ceylon oil which he considers identical with common camphor. Weber (*Ann. Ch. Ph.,* ccxxxviii, 98) found a small amount of a crystalline non-volatile compound which fuses at 60° to 61° C. (140°–141.8° F.). Schimmel & Co. published in their semi-annual reports for April and October, 1897, some results of investigation of several varieties of cardamom oil. The terpenes of Ceylon oil they state to be *terpinene* and *dipentene;* both Ceylon and Bengal cardamom contain *cineol,* $C_{10}H_{18}O$; Malabar cardamom yields *terpineol* as well as cineol, while Siam cardamom yields a crystalline sediment composed of borneol and camphor in approximately equal proportions. The sp. gr. of the oil is between 0.92 and 0.94. It cannot be kept long without undergoing change, and finally, even though excluded from the air, loses its peculiar odor and taste. If ether be made to percolate through the powdered seeds, and the liquor obtained be deprived of the ether, a light greenish-brown fluid remains, consisting almost exclusively of the volatile and fixed oils. It has the odor of cardamom, and keeps better than the oil obtained by distillation. (*A. J. P.,* xxi, 116.) The oil of cardamom of commerce is often factitious, being composed of several cheap volatile oils, oils of cajuput, nutmeg, and others being used. Schimmel & Co. announced in 1901 that they no longer distilled the oil from the fruit of *Elettaria cardamomum,* but from the seeds of another species; this oil makes a clear solution with three parts by volume of 70 per cent. alcohol. (*Schim. Rep.,* 1901, 14.) See *Oil of Cardamom,* N. F. IV., Part II. The seeds should be powdered only when wanted for use, as they retain their aromatic properties best while in the capsule.

Cardamoms are sometimes adulterated; G. W. Kennedy reported nearly 4 per cent. of orange seeds and unroasted grains of coffee admixed with cardamom. Solstein (1892) found that pure powdered cardamom yields 8.36 per cent. of ash; three commercial samples of powdered cardamom that he examined contained sodium carbonate.

Uses.—Cardamom is a grateful aromatic, not strongly heating or stimulating, and useful chiefly as an adjuvant. Throughout the East Indies it is largely consumed as a condiment. It was known to the ancients, and derived its name from the Greek language. In this country it is employed chiefly as an ingredient in compound preparations.

Dose, fifteen to thirty grains (1–2 Gm.).

CARUM. U. S. (Br.)

CARAWAY [Carawayseed, Caraway Seed]

(cā'rŭm)

"The dried fruit of *Carum Carvi* Linné (Fam. *Umbelliferæ*). Without the presence or admixture of more than 3 per cent. of other fruits, seeds or foreign matter. Preserve Caraway in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." *U. S.* "Caraway Fruit is the dried ripe fruit of Carum Carvi, *Linn.*" *Br.*

Carui Fructus, *Br.*; Caraway Fruit; Carvies, Cumin des Prés, Carvi, *Fr. Cod.*; Fructus Carvi, *P. G.*; Gemeiner Kümmel, Kümmel, Garbe, *G.*

The caraway plant is biennial and umbelliferous, with a spindle-shaped, fleshy, whitish root, and an erect stem, about two feet in height, branching above, and furnished with doubly pinnate, deeply incised leaves, the segments of which are linear and pointed. The flowers are small and white, and in erect terminal umbels, with an involucre, consisting sometimes of three or four bracts, sometimes of one only, and are destitute of partial involucre.

It is a native of Europe, growing wild in meadows and pastures, and cultivated in many places. It has been introduced in many places in this country, especially in the North. The flowers appear in May and June, and the seeds, which are not perfected until the second year, ripen in August. The root, when improved by culture, resembles the parsnip, and is used as food in Northern Europe. The fruits are the part used in medicine. They are collected by cutting down the plant, and threshing it on a cloth. Our markets are supplied partly from Europe, partly from our own gardens. The American fruits are usually rather smaller than the German. Under the name of *Ajowan,* the fruits of the *Carum Ajowan,* Bentham & Hooker (*Ammi copticum* L.) are largely used in India. (See *Ajowan,* Part II.) They contain about 4 per cent. of a volatile oil, which has the odor of the oil of thyme, and contains thymol; it may be used as an aromatic carminative. (See *B. M. J.,* June 6, 1885.) For a description of the *oil of ajowan,* see p. 745.

Caraway is officially described as follows: "Mericarps usually separated, crescent-shaped, 3 to 7 mm. in length, 1.5 mm. in diameter; externally dark brown with 5 yellowish filiform ribs; in transverse section nearly equilaterally pentagonal, the commissural surface with two vittæ, the dorsal surface with a vitta between each of the primary ribs; oily endosperm large, enclosing a small embryo; odor and taste agreeably aromatic. Under the microscope, transverse sections of Caraway show an epidermal layer of slightly tangentially elongated cells with thick outer walls; a layer of several rows of tangentially elongated parenchyma cells, frequently more or less collapsed; a single, large, elliptical, brown vitta or oil-tube between each of the ribs and surrounded by small epithelial or secretion cells; in each of the ribs a single fibrovascular bundle surrounded by a layer of thick-walled sclerenchymatous fibers; inner epidermis of broadly elongated cells with very thin side walls, being very frequently broken and closely coherent with the more or less brownish collapsed cells of the seed-coat; commissural surface with 2 large vittæ and at the middle portion 2 large tranverse hollow spaces formed by the separation of the tissues of the seed-coat on one side and the pericarp on the other, otherwise, the cells resemble those on the dorsal surface; endosperm large, cells polygonal with thick walls and containing a fixed oil and aleurone grains, the latter not infrequently containing a small rosette aggregate or prism of calcium oxalate. The powder is yellowish-brown, mostly of irregular, angular fragments; cells of endosperm with aleurone grains each usually containing a rosette aggregate of calcium oxalate about 0.001 mm. in diameter; fragments with light-yellow vittæ, together with nearly isodiametric or polygonal, yellowish-brown, inner epidermal cells of pericarp; fragments with tracheæ and sclerenchymatous fibers, the latter 0.01 mm. in width, slightly lignified and with numerous oblique pores. Caraway yields not more than 8 per cent. of ash." *U. S.*

"Mericarps usually separate; each from about four to six millimetres long and about one millimetre broad; brown with paler primary ridges; slightly curved, tapering towards each end, and glabrous. In transverse section, six vittæ in each mericarp. Odor and taste aromatic. Ash not more than 9 per cent." *Br.*

They have an agreeable aromatic odor, and a sweetish, warm, spicy taste. These properties depend on an essential oil, which they afford largely by distillation. (See *Oleum Cari.*) The residue is insipid. They yield their virtues readily to alcohol and more slowly to water.

"Drawn caraway seeds," a term applied to such as have been recovered from the still residue after obtaining the volatile oil, are used to adulterate caraway; the exhausted "seeds" are much darker in color than are the genuine and are less odorous. (*P. J.,* 1896, 150.) While this is the principal form of adulteration, they may contain large amounts of stems, gravel, sand, dust, weed seeds and other impurities.

Uses.—Caraway is a pleasant stomachic and carminative, occasionally used in *flatulent colic,* and as an adjuvant or corrective of other medicines. The dose in substance is from fifteen to thirty grains (1–2 Gm.). An infusion may be prepared by adding two drachms of the seeds to a pint of boiling water. The volatile oil, however, is most employed. (See *Oleum Cari.*) Three and a half ounces of the oil of caraway caused violent vomiting and abdominal pain, with loss of consciousness, ending, however, in recovery. The urine contained both acetone and albumin. (*Cb. I. M.,* xxii, 1902.) In culinary operations the seeds are added to cakes, to

which they communicate an agreeable flavor, while they stimulate the digestive organs.

Dose, fifteen to thirty grains (1–2 Gm.).

CARYOPHYLLUS. U. S. (Br.)

CLOVE Caryoph. [Cloves]

(căr-ȳ-o-phȳl'lŭs)

"The dried flower-buds of *Eugenia aromatica* (Linné) O. Kuntze, *Jambosa Caryophyllus* (Sprengel) Niedenzu (Fam. *Myrtaceæ*), without the presence or admixture of more than 5 per cent. of the peduncles, stems or other foreign matter." *U. S.* "Cloves are the dried flower-buds of Eugenia caryophyllata, *Thunb.*" *Br.*

Caryophyllum, *Br.*; Caryophylli Aromatici; Girofle, *Fr. Cod.*; Géroflе, Clous Aromatiques, Clous de Girofle, *Fr.*; Caryophylli, *P. G.*; Gewürznelken, Nägelein, *G.*; Garofani, *It.*; Clavo de especia, *Sp.*; Cravo da India, *Portug.*; Kruidnagel, *Dutch*; Kerunfel, *Arab.*

Eugenia aromatica (L.), O. Kuntze, is a small tree inhabiting the Molucca Islands and Southern Philippines. It has a pyramidal form, is always green, and is adorned throughout the year with a succession of beautiful rosy flowers. The stem is of hard wood, and covered with a smooth, grayish bark. The leaves are opposite, petiolate, about four inches in length by two in breadth, obovate-oblong, acuminate at both ends, entire, sinuated, with many parallel veins on each side of the midrib. They have a firm consistence and a shining green color, and when bruised are highly fragrant. The flowers are disposed in terminal corymbose panicles, and exhale a strong, penetrating, and grateful odor.

The natural geographical range of the clove is extremely limited, being confined to the Molucca or, as they were one time called, Clove Islands. According to Flückiger, cloves were known in Western Europe as early as the sixth century, long before the discovery of the Moluccas by the Portuguese. After the conquest of the Molucca Islands by the Dutch, the monopolizing policy of that commercial people led them to extirpate the trees in nearly all the islands except Amboyna and Ternate, which were under their immediate inspection. Notwithstanding their jealous vigilance, a French governor of the Islands of France and Bourbon, named Poivre, succeeded, in the year 1770, in obtaining plants from the Moluccas and introducing them into the colonies under his control. Five years afterwards the clove-tree was introduced into Cayenne and the West Indies, in 1803 into Sumatra, and in 1818 into Zanzibar. At present the spice is cultivated both in the West and East Indies, in tropical Africa, and in Brazil. Approximately seven-eighths of the world's clove supply is grown in Zanzibar, the deliveries in 1911 totaled over 20,000,000 pounds. The amount imported in the United States is approximately 3,500,000 pounds annually.

The unexpanded flower buds are the part of the plant employed under the ordinary name of cloves. They are first gathered when the tree is about six years old. The fruit has similar aromatic properties, but much weaker. The buds are at first white, then become green, and then bright red, when they must be at once collected, which is done by hand picking, or by beating the trees with bamboos and catching the falling buds. In the Moluccas they are said to be sometimes immersed in boiling water and afterwards exposed to smoke and artificial heat before being spread out in the sun. In Zanzibar, Cayenne, and the West Indies they are dried simply by solar heat. The stems of the flowers also enter commerce. They possess the odor and taste of the cloves, but they are worth only about one-fifth the price of the cloves, as they are deficient in volatile oil. They are largely used as an adulterant in ground cloves, and are used in the manufacture of oil of cloves. In France they are generally known by the name of *griffes de girofle*.

Although it is stated that as early as 266 B.C., during the reign of the Han dynasty, the Chinese court officers were accustomed to hold cloves in their mouths before addressing the sovereign, that their breath might have an agreeable odor, the spice seems to have been first introduced into Europe in the fourth century, and became a great source of wealth to the enterprising merchants of mediæval Venice, who obtained it from the Arabians. After the discovery of the southern passage to India, the trade in this spice passed into the hands of the Portuguese, but was subsequently wrested from them by the Dutch, by whom it was long monopolized. The United States derive much of their supply from the West Indies and Guiana; but the great sources of cloves have been recently the islands of Zanzibar and Pemba, on the east coast of Africa. In 1872 the clove orchards in Zanzibar were nearly nestroyed by a hurricane, but they have been replanted. (For detailed information as to method of growth, see *P. J.*, June, 1890.) In commerce the varieties of cloves are known by the names of the localities of their growth, and so closely resemble one another as to be distinguished only by experts. The *Penang cloves* have been especially esteemed. The *Bencoolen cloves* from Sumatra are by many druggists deemed equal to them. The Amboyna and Molucca cloves are stated to be thicker, darker, heavier, more oily, and more highly aromatic than those cultivated elsewhere. Formerly cloves were frequently adulterated, but the comparatively low price of later times has discouraged this fraud. (See Kraemer, *Proc. A. Ph. A.*, 1894, 159.)

Properties.—Cloves resemble in shape a nail with a round head with four spreading points beneath it.

"From 10 to 17.5 mm. in length, of a dark

brown or brownish-black color, consisting of a stem-like, solid, inferior ovary, obscurely four-angled or somewhat compresed, terminated by four calyx teeth, and surmounted by a nearly globular head, consisting of four petals, which enclose numerous curved stamens and one style; odor strongly aromatic; taste pungent and aromatic, followed by slight numbness. When Clove is pressed strongly between the thumbnail and finger the volatile oil becomes visible. Stems either separate or attached to the flower-buds; sub-cylindrical or four-angled, attaining a length of 25 mm. and a diameter of 4 mm., either simple, branching or distinctly jointed, and less aromatic than the flower-buds. The powder varies from dark brown to reddish-brown and consists chiefly of cellular fragments showing the large oil reservoirs, spiral tracheæ and a few somewhat thick-walled, slightly-lignified, spindle-shaped bast-fibers; calcium oxalate in rosette aggregates, from 0.01 to 0.015 mm. in diameter; pollen grains numerous, tetrahedral, somewhat ellipsoidal, from 0.015 to 0.02 mm. in diameter. The presence of stems in the powder is shown by stone cells of irregular, polygonal shape, 0.07 mm. in diameter, with thick porous walls and large lumina, the latter frequently filled with a yellowish-brown amorphous substance. Clove yields not less than 10 per cent. of volatile extractive soluble in ether (see Part III, Test No. 12). Clove yields not more than 8 per cent. of ash. The amount of ash, insoluble in hydrochloric acid, does not exceed 0.5 per cent. of the weight of clove taken." *U. S.*

"About fifteen millimetres long, each consisting of a dark-brown, wrinkled, subcylindrical, somewhat angular calyx tube which tapers below and is surmounted by four thick, rigid, patent teeth, between which are four paler, imbricated petals enclosing numerous stamens and a single style. Odor strong, fragrant and spicy; taste very pungent and aromatic. Cloves emit oil when indented with the finger-nail. Ash not more than 7 per cent." *Br.*

Their color is externally deep brown, internally reddish; their odor strong and fragrant; their taste hot, pungent, aromatic, and very permanent. The best cloves exude a small quantity of oil on being pressed or scraped with the nail. When light, soft, wrinkled, pale, and of feeble taste and odor, they are inferior. Those from which the essential oil has been distilled are sometimes fraudulently mixed with the genuine. For monograph on the microscopical structure of cloves, clove stems and clove fruit see Winton and Moeller, "*The Microscopy of Vegetable Foods.*" Powdered cloves sometime contain an excess of clove stems, and may be adulterated with allspice, wheat middlings and powdered peas or beans. Occasionally clove stems alone are ground and sold as cloves. It is claimed that an enormous quantity of exhausted cloves are dishonestly marketed. The amount of volatile ether extract is the best criterion of the value of cloves.

Trommsdorf obtained from 1000 parts of cloves 180 of volatile oil, 170 of a peculiar tannin, 130 of gum, 60 of resin, 280 of vegetable fiber, and 180 of water. Wm. L. Peabody (1895) found the percentage of tannin in cloves to range from 10 to 13 per cent., and that it has the same chemical composition as gallotannic acid. Lodibert afterwards discovered a fixed oil, aromatic and of a green color, and a white resinous substance which crystallizes in fasciculi composed of very fine diverging silky needles, without taste or odor, soluble in ether and boiling alcohol, and exhibiting neither alkaline nor acid reaction. This substance, called by Bonastre *caryophyllin*, was found in the cloves of the Moluccas, of Bourbon, and of Barbados, but not in those of Cayenne, from which, however, it has since been procured. To obtain it, the ethereal extract of cloves is treated with water, and the white substance thrown down is separated by filtration, and treated repeatedly with ammonia to deprive it of impurities. The most recent determination of its formula by Mylius (*Ber. d Chem. Ges.*, 1873, p. 1053) makes it $C_{20}H_{32}O_2$. Theod. Martius obtains it cheaply by exposing cloves, previously deprived as far as possible of oil by distillation with water, to distillation at a higher temperature, redistilling the brown liquid obtained until the distillate nearly ceases to have the taste or odor of cloves, and then purifying the residue by washing with water, and treating it with boiling alcohol and animal charcoal repeatedly until the caryophyllin, which is deposited by the alcohol on cooling, is perfectly white. (See *A. J. P.*, xxxii, 65.) Dumas has discovered another crystalline principle, which forms in the water distilled from cloves, and is gradually deposited. Like caryophyllin, it is soluble in alcohol and ether, but differs from that substance in becoming red when touched with nitric acid. Bonastre proposed for it the name of *eugenin*. (*J. P. C.*, xx, 565.) It has the formula $C_{10}H_{12}O_2$, and is isomeric with eugenol or eugenic acid, a constituent of oil of cloves. Water extracts the odor of cloves with comparatively little of their taste. All their sensible properties are imparted to alcohol; and the tincture when evaporated leaves an excessively fiery extract, which becomes insipid if deprived of the oil by distillation with water, while the oil which comes over is mild. Hence it has been inferred that the pungency of this aromatic depends on a union of the essential oil with the resin. *Caryophyllic acid*, $C_{20}H_{32}O_3$, is obtained by gradually adding caryophyllin to fuming nitric acid, kept cool by immersing the vessel in water until crystals begin to separate; these are purified by dissolving them in ammonia, precipitating with hydrochloric acid, and redissolving in alcohol and crystallizing. For an account of the oil, see *Oleum Caryophylli*. The infusion and oil of cloves are reddened by nitric acid, and rendered blue by tincture of ferric

chloride, facts of some interest, as morphine gives the same reactions.

Uses.—Cloves are among the most stimulant of the aromatics, but, like others of this class, act less upon the system at large than on the part to which they are immediately applied. They are sometimes administered in substance or infusion to relieve *nausea* and *vomiting*, correct *flatulence*, and excite *languid digestion;* but their chief use is to assist or modify the action of other medicines. They enter into several official preparations.

The French Codex directs a *tincture of cloves* to be prepared by digesting for ten days, and afterwards filtering, a mixture of three ounces of powdered cloves and sixteen of 80 per cent. alcohol.

Dose, in substance, from five to ten grains (0.32 to 0.65 Gm.).

CASCARA SAGRADA. U. S., Br.

CASCARA SAGRADA. Casc. Sagr. [Rhamnus Purshiana U.S. VIII]

(kăs-kă'ra sa-grä'da)

"The dried bark of the trunk and branches of *Rhamnus Purshiana* De Candolle (Fam. *Rhamnaceæ*)." *U. S.* "Cascara Sagrada is the dried bark of Rhamnus Purshianus, *DC.*, collected at least one year before being used." *Br.*

Rhamni Purshiani Cortex, *Fr. Cod.;* Sacred Bark; Chittem Wood Bark, Dogwood bark, Coffee-berry bark, Pigeonberry bark, Bear-berry bark, Bitter bark and Yellow bark; Cascara Sagrada, *Sp.*

A number of species of Rhamnus have been described as growing in California, but according to the best authority there are only four species,—*R. alnifolia,* L'Her., *R. crocea,* Nutt., *R. Purshiana,* DC., and *R. californica,* Esch. Of these species, *R. alnifolia* is too rare in the Cascara district to be important; while the spinescent twigs, the very thick oval or roundish leaves, and the small roundish red fruit of *R. crocea* make it so distinct that it cannot be confounded with the Cascara, whose bark, moreover, it does not resemble. On the other hand, *R. californica* appears to be very commonly confounded with the official species by collectors, and to have yielded some of the cascara sagrada bark of commerce. *R. californica* is rare in Northern California, but abundant in the countries lying south and southeasterly, while *R. Purshiana* is abundant in Northern California, but scarce in the south, so that any bark collected in Northern California is probably genuine. *R. californica* is chiefly distinguished from the official species by its leaves being thin, and, when not smooth, having a short close pubescence, and the primary veins of the under surface not nearly so numerous, straight, or fine as those of *R. Purshiana.* Rusby thinks that its leaves are especially distinguished by the channel of the midrib of *R. californica* being altogether absent, or shallow, or inconspicuous. Nevertheless the species so run into one another that competent botanists believe them identical.

The *Rhamnus Purshiana* is a small tree, attaining a height of twenty feet. Its leaves are rather thin, elliptic, for the most part briefly acutely pointed, finely serrated, at the base obtuse, somewhat pubescent beneath, from two to seven inches long and from one to three wide. The rather large flowers are in somewhat umbellate cymes; the sepals five; the minute cucullate petals bifid at the apex. The fruit is black, broadly obovoid, four lines long, three-lobed, and three-seeded. The seeds are convex on the back, with a lateral raphe. It is found in California, extending northward to the British territories. For details of manner of collecting the bark see an elaborate and illustrated article by Johnson and Hindman, *A. J. P.*, 1914, p. 387. The amount of Cascara that is collected annually varies between 3,000,000 and 4,000,000 pounds. Because of the rapid destruction of natural sources of the bark in the Western United States, experiments have been conducted by the Bureau of Plant Industry, U. S. Department of Agriculture, Washington, D. C., to cultivate it.

The *Rhamnus californica,* or *Californian buckthorn* or *California coffee-tree,* yields a bark which is of a dark brown color externally and bright yellow internally, having an intensely bitter taste, with a persistent nauseous aftertaste, and very little odor. It is said to be much more distinctly purgative than that of *R. crocea.*

It does not seem possible to distinguish with certainty between the barks of the two species by their macroscopic appearance. The bark of *R. Purshiana* is usually more red than is that of *R. californica,* but it may be of a distinctly gray color. The microscopic structure of the two barks is, however, different. The medullary rays in *R. Purshiana* are numerous, thin, for a long distance nearly parallel and straight (according to L. E. Sayre, they converge at their outer ends), run nearly three-quarters of the distance through the bark, and are commonly composed of two rows of cells. In *R. californica* the medullary rays are much broader, much shorter, and are composed usually of three or more rows of cells; further, they are crooked and not parallel throughout their course. Again, the zone of resin spaces is much broader in *R. californica,* and the spaces themselves much larger and more numerous than in the official species. For further details and elaborations, see papers by H. H. Rusby, *Proc. A. Ph. A.*, 1890, and by Gathercoal, *J. A. Ph. A.*, 1915, p. 15. According to L. E.

Sayre (*A. J. P.*, March, 1897), the powder of the barks can be distinguished by paying attention to the fact that *R. Frangula* contains no stone cells, while in *R. californica* and *R. Purshiana* such cells are abundant, occurring in large, irregular groups below the cork and usually outside the region of the bast: *R. Purshiana* may also be distinguished from *R. californica* by color tests. After several days' maceration in dilute alcohol the powder of *R. Purshiana* appears of an orange-yellow color, *R. californica* of a purplish color; or if 0.2 Gm. of the powdered bark be placed in a small test tube, and there be added 2 mils of potassium hydroxide test solution, *R. californica* will give a blood-red and *R. Purshiana* an orange-red color.

The bark of the *Rhamnus crocea*, the so-called *California mountain holly*, occurs in slightly curved pieces, externally of a dark brown color, internally of a characteristic red delicately streaked with numerous white veins. The odor is somewhat aromatic, the taste warming and not unpleasantly bitter. It is affirmed to be a tonic and mild laxative.

Properties.—Cascara sagrada occurs in commerce in the form of small broken pieces, often more or less flattened out into a somewhat compressed mass, and also as separated quills of varying length and size. The bark is "Usually in flattened or transversely curved pieces, occasionally in quills; bark from 1 to 5 mm. in thickness; outer surface dark brown or brownish-red, longitudinally ridged, often nearly covered with grayish or whitish lichens, bearing small blackish apothecia, sometimes with numerout lenticels, and occasionally with mosses; inner surface light yellow, light brown, or reddish-brown, longitudinally striate, turning red when moistened with solutions of the alkalies; fracture short, with projections of bast-fibers in the inner bark; in cross section inner bark shows diagonal or curved medullary rays, forming converging groups, the outer bark showing yellowish groups of stone cells which are especially apparent on moistening the freshly cut surface with phloroglucinol T.S. and hydrochloric acid; odor distinct; taste disagreeable, bitter, and slightly acrid. Under the microscope, a transverse section of Cascara Sagrada shows an outer yellowish-brown or reddish-brown corky layer consisting of 10 to 15 or more rows of cells; stone cells in outer bark in tangentially elongated groups of 20 to 50 cells, the walls being very thick and finely lamellated; medullary rays 1 to 4 cells wide, 15 to 25 cells deep, the contents being colored red upon the addition of solutions of the alkalies to the sections; bast-fibers in tangentially elongated groups in the inner bark, the walls being thick and strongly lignified; crystal fibers around the bast-fibers with individual crystals from 0.008 to 0.015 mm. in length; parenchyma with spheroidal starch grains about 0.003 to 0.008 mm. in diameter, or with calcium oxalate either in rosette aggregates or prisms from 0.01 to 0.02 mm. in diameter. Add 0.1 Gm. of powdered Cascara Sagrada to 10 mils of hot water, shake the mixture occasionally until cold, filter it and add sufficient water to make 10 mils; on the addition of 10 mils of ammonia water to this liquid, it is colored an orange-yellow. Macerate 0.1 Gm. of powdered Cascara Sagrada with 10 drops of alcohol, boil the mixture with 10 mils of water, when cold filter it and shake the filtrate with 10 mils of ether; a yellow ethereal solution separates. Shake 3 mils of this ethereal solution with 3 mils of ammonia water; the separated ammoniacal solution still possesses, on diluting with 20 mils of water, a distinct, yellowish-red color. The powder is light brown to olive brown, showing characteristic elongated groups of bast-fibers associated with crystal fibers, the crystals in the latter being in the form of monoclinic prisms from 0.008 to 0.015 mm. in length; stone cells in large groups, the cells having thick and finely porous walls; fragments of parenchyma and medullary ray cells colored red upon the addition of solutions of the alkalies; starch grains either free or in parenchyma cells, the individual grains being somewhat spheroidal, from 0.003 to 0.008 mm. in diameter; calcium oxalate in monoclinic prisms or rosette aggregates from 0.01 to 0.02 mm. in diameter; occasional fragments of reddish-brown cork." *U. S.*

"In quilled, channelled, or nearly flat pieces from one to two millimetres thick, but varying in length and width. Cork nearly smooth, dark purplish-brown, marked with transversely elongated lenticels, but usually more or less covered with patches of silvery-grey lichen. Inner surface reddish-brown, with faint transverse corrugations and longitudinal striations. Fracture short, but near the inner surface somewhat fibrous. In transverse section, scattered groups of sclerenchymatous cells in both cortex and bast; the parenchymatous cells contain a yellow substance which is colored violet by *solution of sodium hydroxide*. Odor characteristic but not powerful; taste nauseous, bitter and persistent." *Br.*

For articles illustrating the pharmacognosy of Cascara bark see Kraemer, *A. J. P.*, 1912, p. 385; Miller, *J. A. Ph. A.*, 1912, p. 1207; and Farwell, *J. A. Ph. A.*, 1914, p. 649. According to the analysis of A. B. Prescott (*N. P.*, Feb., 1879), it contains a very bitter brown resin (which is colored a vivid purple-red by potassium hydroxide); a red resin; a light yellow resin; tannic, malic, and oxalic acids; a neutral crystallizable substance; and a volatile oil. H. F. Meier and J. Le Roy Webber have pointed out in addition the presence of a ferment, glucose, and ammonia. According to these investigators, to the action of the ferment are attributed the unpleasant results attending the administration of "fresh bark"; "seasoned bark" —*i.e.*, such as has been kept a year or two— owes its valuable properties as a laxative, *free from griping*, to the fact that the ferment has

exhausted itself; the laxative properties, they state, reside in the resins, and the tonic effects are due to the crystalline principle. (*A. J. P.*, 1888, 91). Schwabe (*A. Pharm.*, ccxxvi, 569) found *emodin*, or trioxymethylanthraquinone, which he believes is the active principle. Dohme and Engelhardt (*Proc. A. Ph. A.*, 1897, 193) have shown the analogy of cascara sagrada with *Rhamnus Frangula* by obtaining a glucoside to which they give the name of *purshianin*. This decomposes, yielding emodin and a dextro-rotatory non-fermentable sugar, while the frangulin of buckthorn yields emodin and rhamnose as the sugar. Purshianin forms brown-red needles, melting at 237° C. (458.6° F.). Dohme and Engelhardt failed to obtain in a pure form (*Proc. A. Ph. A.*, 1898, 340) the bitter principle of cascara sagrada. Le Prince (*C. R. A. S.*, 1892, 286) claimed to have obtained the active principle of cascara bark in a crystalline form, which he named *cascarine;* his results are doubted by Jowett who believes that cascarine and purshianin are impure forms of emodin. Jowett (*Proc. A. Ph. A.*, 1904, 288) in an exhaustive paper concludes that the active principle of cascara is contained in that portion of an alcoholic extract which is soluble in water and precipitable by lead subacetate and in that portion of the regenerated lead subacetate precipitate which is soluble in ethyl acetate. Pietsch states that a glucoside from the bark of cascara sagrada which has been named *peristaltin* has the composition $C_{14}H_{18}O_8$. (*Th. M.*, 1910, No. 1, p. 35.)

Uses.—Cascara sagrada belongs to the group of vegetable cathartics whose activity depends upon the presence of one or more oxides of methylanthraquinone. This group includes aloes, cascara, rhubarb, and senna. In cascara the active principle appears to be emodin, which is trioxymethylanthraquinone, and which appears also to be the purgative principle of aloes. The action of this principle is chiefly to excite peristalsis in the colon, although after large doses there is probably also some effect upon the upper bowel. As the action is chiefly upon the lower intestine it is not to be recommended as a laxative where it is desired to clean out the bowel, but in the treatment of *chronic constipation* it acts very favorably. It often appears to restore tone to the relaxed bowel and in this way produce a permanent beneficial effect. The bark itself is rarely used, either the extract or fluidextract being eligible preparations.

The addition of belladonna to overcome any tendency to gripe is an advantage. Ordinarily a single dose is given at bedtime but in some cases better results are obtained by exhibiting smaller doses after meals.

Dose, ten to thirty grains (0.6–2.0 Gm.).

CASCARILLA. Br.

CASCARILLA

(căs-cą-rĭl'lą)

"Cascarilla is the dried bark of Croton Eluteria, *J. J. Benn.*" *Br.* "The dried bark of *Croton Eluteria* (Linné) Bennett (Fam. *Euphorbiaceæ*), without the presence of more than 5 per cent. of adhering wood." *N. F.*

Cascarillæ Cortex, *Br.* (1885), Cascarilla Bark, Sweet Bark, Sweetwood Bark; Cascarille officinale, *Fr. Cod.;* Cortex Eluteriæ, Cortex Thuris; Chacrille, Ecorce éleuthérienne Cascarille, *Fr.;* Cortex Cascarillæ, *P. G.;* Cascarillrinde; Cascarilla, Kaskarillrinde, *G.;* Cascarilla, Cascariglia, *It.*, Chacarilla, Quina aromatica, *Sp.*

Croton Eluteria is a shrub or a small tree with a stem from four to eight inches in diameter. The stem is straight, and marked at intervals with white or grayish stains. The leaves are petiolate, often somewhat cordate at the base, obtusely acuminate, pale or grayish-green above, and densely covered beneath with shining silvery scales, appearing white at a distance. They are smaller and narrower in the plants of arborescent growth. The flowers, which have a delicious odor, are monœcious, small, white, petiolate, and closely set in simple terminal or axillary spikes. The shrub is a native of the Bahamas, scarce at present in the island of New Providence, but still abundant in Andros, Long, and Eleutheria islands, from the latter of which is derived its botanical title. Daniell calls the plant *sweetwood*. The name of *sea-side balsam* belongs to another species, *C. balsamiferum* of Linnæus, which grows in the Bahamas and other West India islands, and owes its name to the exudation of a balsamic juice from its young branches when wounded.

Under the name of "cascarilla," also "*Quina morada*," the bark of the *Pogonopus febrifugus* is said to be used in the Argentine Republic as a substitute for cinchona bark. There has been separated from it a blue fluorescent substance, *moradin*, and an alkaloid, *moradeine*. (*P. J.*, xx, 854.)

Copalchi bark has been mistaken not only for cascarilla, but also for a variety of cinchona. Portions of it, having been taken to Europe, attracted the attention both of pharmacologists and physicians. Two kinds were noticed: one, in small slender quills, of an ash color, bearing some resemblance to a variety of pale cinchona, but having the flavor of cascarilla, and burning with a similar odor; the other in larger quills, with a thick cork-like epidermis, very bitter, and yielding an aromatic odor when burnt. The former is the product of *Croton Pseudochina*,

Schlechtendal (*C. niveus* Jacquin); the latter is of unknown origin, but conjecturally referred to *C. suberosus*. J. E. Howard states that the quilled copalchi bark contains a bitter alkaloid, soluble in ether, and precipitable as a white hydroxide from its acid solution. (*P. J.*, xiv, 319.) Copalchi bark is an aromatic tonic, employed in Mexico in intermittents, and capable of useful application in all cases requiring a mild aromatic bitter. Stark has employed it advantageously in feeble states of digestion with irritable bowels, and found it in one or two cases, to exhibit antiperiodic properties. It may be given in infusion, made with half an ounce of the bark to a pint of water, in the dose of one or two fluidounces three times a day. (*Ed. Med. and Surg. Journ.*, April, 1849, p. 410; see also *P. J.*, 1886, p. 917.)

Croton Cascarilla Bennett, known in the West Indies as *wild rosemary*, was at one time said to furnish the cascarilla of commerce. The bark is also substituted by the barks of *Croton glabellus* L. and *C. lucidus* L. of the Bahamas and which were formerly designated as the "mother plants" of Cascarilla. They are not aromatic but astringent and slightly bitter. They are also distinguished by the presence of stone cells which are wanting in true Cascarilla. (See *U. S. D.*, 19th ed.)

Cascarilla is brought to this market from the West Indies, and chiefly, we have been informed, from the Bahamas. It comes in bags or casks. We have observed it in commerce in two forms, so distinct as to merit the titles of varieties. In one, the bark is in rolled pieces of every size, from three or four inches in length and half an inch in diameter to the smallest fragments, covered externally with a dull whitish or grayish-white epidermis, which in many portions is partially, sometimes wholly removed, leaving a dark brown surface, while the inner surface has a chocolate color, and the fracture is a reddish-brown. The small pieces are sometimes curled, but have a distinct abrupt edge as if broken from the branches. The second variety consists entirely of very small pieces, not more than an inch or two in length, very thin, without the white cork, not regularly quilled, but curved more or less in the direction of their length, often having a small portion of woody fiber attached to their inner surface, and appearing precisely as if shaved by a knife from the stem or branches. Whether these two varieties are derived from distinct species, or differ only because of the mode of collection, it is difficult to determine. A. W. Southall describes a bark (believed to belong to the genus *Croton*, and obtained from Colombia) in *P. J.*, 1894, 574.

"In quills usually from three to ten centimetres in length and from four to twelve millimetres in diameter, or in small curved pieces. Cork greyish-white, easily detached, and often more or less completely removed disclosing a dull brown cortex. Both cork and cortex frequently marked with numerous longitudinal and transverse cracks. Fracture short, the fractured surface exhibiting under a lens a dark reddish-brown bast traversed by numerous, thin, whitish medullary rays. In transverse section cork cells with strongly thickened outer walls, but thin inner walls, in which minute crystals of calcium oxalate are embedded; both cortex and bast free from sclerenchymatous cells. Aromatic odor, especially when burned; taste aromatic and bitter. Ash not more than 11 per cent." *Br.*

The National Formulary describes it as "in quills or curved pieces from 0.5 to 2.5 mm. in thickness, externally gray, somewhat fissured; the corky layer easily detached, more or less coated with a white lichen; the uncoated surface dull-brown, inner surface smooth; fracture short, the fractured surface having a resinous and radially striate appearance. Odor characteristic, strong and musk-like when the bark is burned; taste warm, aromatic and very bitter. The powdered drug is pale-brown and has an odor resembling that of clove. When examined under the microscope, it exhibits simple starch grains up to 0.013 mm. in diameter and occasionally two- to three-compound; calcium oxalate in monoclinic crystals or rosette aggregates up to 0.025 mm. in diameter; fragments of parenchyma tissue, some of the cells containing starch, calcium oxalate or tannin; cells filled with reddish-brown resin or yellow oil; somewhat lignified cork cells, polygonal in outline with evenly thickened, lamellated walls and irregular lumina; non-porous bast fibers, some with lignified walls, up to 0.016 mm. in diameter; tracheæ with bordered pores very few or absent. Cascarilla yields not more than 10 per cent of ash." *N. F.*

Cascarilla should yield not more than 10 per cent. of ash.

Properties.—Cascarilla has an aromatic odor, rendered much more distinct by friction, and a warm, spicy, bitter taste. It is brittle, breaking with a short fracture. When burned it emits a pleasant odor, closely resembling that of musk, but weaker and more agreeable. This property serves to distinguish it from other barks. It was analyzed by Trommsdorff, and more recently by Duval of Lisieux, in France. The constituents found by the latter were albumen, a peculiar kind of tannin, a bitter crystallizable principle called *cascarillin*, a red coloring matter, fatty matter of a nauseous odor, wax, gum, volatile oil, resin, starch, pectic acid, potassium chloride, a salt of calcium, and lignin. The oil, according to Trommsdorff, constitutes 1.6 per cent., is of a greenish-yellow color, has a penetrating odor analogous to that of the bark, and is of the sp. gr. 0.938. G. Feudler (*A. Pharm.*, 1900, p. 671) finds the oil to contain about 2 per cent. of free acid, which consists of a liquid acid, $C_{11}H_{20}O_2$, to which the name of *cascarillic acid* was given, and a solid portion made up of a mixture of palmitic and stearic acids. The oil contains 0.3 per cent. of eugenol, a terpene differing from pinene, cymene, possibly some l-limonene, two sesqui-

terpenes and an alcohol, $C_{15}H_{23}OH$. To obtain cascarillin, Duval treated the powdered bark with water, added lead acetate to the solution, separated the lead by hydrogen sulphide, filtered, evaporated with the addition of animal charcoal, filtered again, evaporated at a low temperature to a syrupy consistence, and having allowed the semi-liquid substance thus obtained to harden by cooling, purified it by twice successively treating it, first with a little cool alcohol, to separate the coloring and fatty matters, and afterwards with boiling alcohol and animal charcoal. The last alcoholic solution was allowed to evaporate spontaneously. Thus obtained, cascarillin is white, crystalline, inodorous, bitter, very slightly soluble in water, soluble in alcohol and ether. (*J. P. C.*, 3e sér., vii, 96.) It melts at 205° C. (401° F.), is not volatile nor a glucoside. Its composition answers to the formula $C_{12}H_{18}O_4$. P. E. Alessandri regards *cascarilline* as an alkaloid, and obtains it economically by mixing powdered cascarilla with sufficient 3 per cent. aqueous solution of oxalic acid to cover it, shaking the mixture, and heating it to 60° C. (140° F.), then allowing it to cool, expressing the mixture and saturating the filtered liquor with ammonia, then evaporating at a low temperature to two-thirds of its bulk, allowing it to cool, and separating any deposit. The clear liquid is then shaken with ether; this takes up the cascarilline, which may be obtained through evaporation of the ethereal liquid. (*L'Orosi*, v, 1; *P. J.*, 1882, 993.) R. A. Cripps was unable to obtain the alkaloid by Alessandri's method, and suggests that the bitterness of the so-called cascarilline might be due to adherent resin. (*P. J.*, 1886, 1103.) Either alcohol or water will partially extract the active matters of cascarilla; but diluted alcohol is the proper menstruum. Naylor and Littlefield have reviewed the processes of Duval and Alessandri for preparing cascarilline, and find that Duval's method gives the purer product. They find its melting point to be 203.5° C. (398.3° F.), and give it the formula $C_{16}H_{24}O_5$. (*Y. B. P.*, 1896, 301.) W. A. H. Naylor subsequently found betaine in cascarilla. (*P. J.*, 1898, 279.)

Uses.—This bark is aromatic and tonic. It was known in Germany as early as the year 1690, and was much used as a substitute for Peruvian bark by those who were prejudiced against that febrifuge in the treatment of *remittent* and *intermittent fevers*. It has, however, lost its reputation, and is now employed only where a pleasant and gently stimulant tonic is desirable, as in *atonic dyspepsia*, and other cases of debility of the stomach or bowels, especially in combination with the more powerful bitters. It may be given in powder or in infusion. In consequence of its pleasant odor when burned, some smokers mix it in a small quantity with their tobacco; but it is said to occasion vertigo and intoxication.

Dose, twenty to thirty grains (1.3–2.0 Gm.).

CASSIÆ FRUCTUS. Br.

CASSIA PODS [Purging Cassia]

(kăs'sĭ-æ frŭc'tŭs)

"Cassia Pods are the ripe fruits of Cassia Fistula, *Linn.*" *Br.* "The dried fruit of *Cathartocarpus Fistula* (Linné) Persoon (Fam. *Leguminosæ*)." *N. F.*

Cassia Fistula. *N. F. IV*, Purging Cassia, Pudding-stick (or pipe); Fructus Cassiæ Fistulæ; Casse Officinale, *Fr. Cod.*; Casse en bâtons, Pulpe de Casse, Casse Mondée, Casse, *Fr.*; Röhrenkassie, Purgircassie, Fistelkassie, *G.*; Cassia, *It.*; Cana fistula, *Sp.*

Cassia Fistula L. (*Cathartocarpus Fistula* Persoon). This is a large tree, with a trunk of hard, heavy wood, dividing towards the top into numerous spreading branches, and covered with a smooth ash-colored bark. The leaves are commonly composed of five or six pairs of opposite leaflets, which are petiolate ovate, pointed, undulated, smooth and of a pale green color. The flowers are large, of a golden yellow color, and arranged in long, pendent, axillary racemes. The fruit consists of long, cylindrical, woody, dark-brown, pendulous pods, which when agitated by the wind strike against each other and produce a sound that may be heard at a distance. This species of Cassia is a native of Upper Egypt and India, whence it is generally supposed to have been transplanted to other parts of the world. It is at present very extensively diffused through the tropical regions of the old and new continents, being found in Insular and Continental India, Cochin China, Egypt, Nubia, the West Indies, and the warmer parts of the continent of America. Under the name of *Golden Shower* it is known as an ornamental shade tree in all tropical countries. The fruit is the official part of the plant. It is imported from the East and West Indies, chiefly the latter, and from South America. Under the name of Cassia Fistula they were for a long time official.

Properties.—Cassia pods are a foot or more in length, straight, or but slightly curved, cylindrical, less than an inch in diameter, with a woody shell, externally of a dark-brown color, and marked with three longitudinal shining bands, extending from one end to the other, two of which are in close proximity, appearing to constitute a single band, and the third is on the opposite side of the pod. These bands mark the place of junction of the valves of the legume, and are represented as sometimes excavated in the form of furrows. There are also circular depressions at unequal distances. It is described as follows: "Long, narrow, cylindrical, shortly stalked fruits about thirty-five to fifty centimetres in length, and fifteen to twenty-five millimetres in diameter. Pericarp nearly smooth, dark chocolate-brown or nearly black, thin and hard. Internally divided by thin transverse dissepiments into numerous

compartments, each of which contains a smooth, oval, reddish-brown seed surrounded by a nearly black, sweet pulp." *Br.*

The N. F. describes it as in "cylindrical, from 25 to 50 cm. in length, about 20 mm. in diameter, chestnut-brown in color, on one side a longitudinal groove and on the other a smooth line or slight ridge, indicating the sutures; indehiscent, the cavity divided transversely into numerous compartments, each containing a reddish-brown, glossy, flattish-ovoid seed embedded in a blackish-brown sweet pulp. Odor resembling that of prunes." *N. F.*

The pods brought from the East Indies are smaller, smoother, have a blacker pulp, and are more esteemed than those from the West Indies. We have seen pods in the American market sold as cassia pods, which were an inch and a half in diameter, flattened on the sides, exceedingly rough on the outer surface, and marked by three longitudinal very elevated ridges, corresponding to the bands or furrows of the common cassia. The pulp was rather nauseous, but in other respects seemed to have the properties of the official purging cassia. They corresponded exactly with a specimen of the fruit of *Cassia brasiliana*, Lam., brought from the West Indies, and were probably derived from that plant.

The heaviest pods, and those which do not make a rattling noise when shaken, are to be preferred, as they contain a larger portion of the pulp, which is the part employed. This should be black and shining and have a sweet taste. It is apt to become sour if long exposed to the air, or mouldy if kept in a damp place. The pulp is extracted from the pods by first bruising them, then boiling them in water, and afterwards evaporating the decoction; or, when the pods are fresh, by opening them at the sutures and removing the pulp with a spatula.

CASSIÆ PULPA. Br.

CASSIA PULP

(kăs'sĭ-æ pŭl'pą)

"Exhaust crushed Cassia Pods by percolation with Distilled Water; strain; evaporate on a water bath to the consistence of a soft extract." *Br.*

Cassia pulp has a slight odor, and a sweet mucilaginous taste. According to Henry it contains sugar, gum, coloring matter, and a tannin-like substance; while Haensel obtained from it by steam distillation a dark yellow volatile oil, also butyric acid. (*Ph. Cb.*, 41.)

Uses.—Cassia pulp is laxative, and may be advantageously given in small doses in cases of *habitual costiveness*. In quantities sufficient to purge, it occasions nausea, flatulence, and griping. In this country it is rarely prescribed, except as an ingredient in the confection of senna, which is a pleasant and useful laxative preparation.

Dose, of the pulp as a laxative, one or two drachms (3.9 or 7.7 Gm.), as a purge one or two ounces (31–62 Gm.).

CATECHU. Br.

CATECHU [Catechu Pallidum]

(kăt'ē-ȼhū)

"Catechu is an extract of the leaves and young shoots of Uncaria Gambier, *Roxb.*" *Br.*

Catechu is described in the Br. Pharm., 1914, as follows: "In cubes, sometimes more or less agglutinated, each side measuring about twenty-five millimetres. Dark reddish-brown externally, pale cinnamon-brown internally, porous and friable. When examined under the microscope they are found to consist chiefly of minute acicular crystals. No odor; taste at first bitter and very astringent, but subsequently sweetish. Almost entirely soluble in boiling *water*. Not less than 80 per cent. is soluble in *alcohol* (90 per cent.); the alcoholic solution made strongly alkaline with *solution of sodium hydroxide* and shaken with *petroleum spirit* imparts to the latter a brilliant green fluorescence (distinction from Black Catechu); the residue insoluble in *alcohol* (90 per cent.) exhibits no starch grains when examined under the microscope. Ash not more than 5 per cent.; ash of the powder not more than 8 per cent." *Br.*

(See *Gambir.*)

CATECHU NIGRUM. Br.

BLACK CATECHU

(kă'tē-ȼhū nī'grŭm)

"Black Catechu is an extract prepared from the wood of Acacia Catechu, *Willd.*" *Br.*

Cutch, Cachou, *Fr.*; Phgu, Katechu, *G.*; Caticu, Catto, *It.*; Catecu, *Sp.*; Cutt, *Hindostanee.*

The U. S. P. (8th Rev.) dismissed catechu and introduced gambir because of the greater uniformity in quality of the latter. See *Gambir*, p. 507.

The U. S. P. 1890 defined catechu as "an extract prepared from the wood of *Acacia Catechu* (Linné fil.) Willdenow (Fam. *Leguminosæ*)."

Acacia Catechu is a small tree, seldom more than twelve feet in height, with a trunk one foot in diameter, dividing towards the top into many close branches, and covered with a thick, rough, brown bark. This species of Acacia is a native of the East Indies, growing abundantly in various provinces of Hindostan, and in the Burmese Empire. It is also common in eastern Africa where it is valued for its wood; but no extract appears to be made from it. Pereira says that its is common in Jamaica.

This drug had been long known before its source was discovered. It was at first called *Terra japonica*, under the erroneous impression

that it was an earthy substance derived from Japan. When ascertained by analysis to be of vegetable origin, it was generally considered by writers on the Materia Medica to be an extract of the *betel nut.* Its true origin was made known by Kerr, assistant surgeon of the civil hospital in Bengal. According to Kerr, the manufacturer, having cut off the exterior white part of the wood, reduces the interior brown or reddish-colored portion into chips, which he then boils in water in unglazed earthen vessels until all the soluble matter is dissolved. The decoction thus obtained is evaporated first by artificial heat, and afterward in the sun, until it has assumed a thick consistence, when it is spread out to dry upon a mat or cloth, being, while yet soft, divided by means of a string into square or quadrangular pieces. The account subsequently given by Royle, of the preparation of the extract in Northern India, is essentially the same. The process, as he observed it, was completed by the pouring of the extract into quadrangular earthen moulds. It is said that the unripe fruit and leaves are also sometimes submitted to decoction. Three colors of catechu are prepared; the light red or red, which is considered best and is especially employed in Burmah and India to chew with the betel nut; the dark red and black, which are made especially for European and American markets, and which are apt to suffer adulteration *en route* in China.

The name *catechu* in the native language signifies the *juice of a tree,* and appears to have been applied to astringent extracts obtained from various plants. Commerce is chiefly supplied with catechu from Bahar, Northern India, and Nepaul through Calcutta, from Canara through Bombay, and from the Burmese dominions. It is frequently called *cutch* by the English traders, a name derived from the Hindostanee word *cutt.*

It enters commerce in large masses, sometimes of one cwt., consisting of layers of flat cakes, frequently wrapped in the leaves of the *Dipterocarpus tuberculatus* Roxb. In this form, however, we do not see it in drug stores, but almost always in angular, irregular fragments, in which portions of two layers sometimes cohere with leaves between them, indicating their origin. It is characterized by its compactness, shining fracture, and blackish-brown or dark port-wine color, so that when finally broken it bears considerable resemblance to kino. This is an excellent variety of catechu.

Catechu is inodorous, with an astringent and bitter taste, followed by a sense of sweetness. It is brittle, and breaks with a fracture which is rough in some specimens, in others uniform, resinous, and shining. That which is preferred in our market is of a dark color, easily broken into small angular fragments, with a smooth glossy surface, bearing some resemblance to kino. Catechu is often mixed with sand, sticks, and other impurities.

Black catechu is described in the Br. Pharm., 1914, as follows: "In irregular masses of a dark brown color, brittle, having a porous, glossy, somewhat conchoidal fracture. Partially soluble in cold *water,* almost entirely soluble in boiling *water.* Not less than 60 per cent. is soluble in *alcohol* (90 per cent.). No odor; taste sweetish, astringent. Its dilute aqueous solution gives a dark green color with *T. Sol. of ferric chloride,* changing to purple when made slightly alkaline with *solution of sodium hydroxide.* Ash not more than 5 per cent.; ash of the powder not more than 8 per cent. In India, in the Eastern, and in the North American Divisions of the Empire, Black Catechu may be employed in making the official preparations for which Catechu is directed to be used." *Br.*

The proportion of tannic acid, which may be considered the efficient principle, varies from about 45 to 55 per cent. in catechu or cutch, and from 36 to 40 per cent. in gambir. The portion designated by Davy as extractive is said to contain, if it does not chiefly consist, of a principle discovered by Buchner, and now called *catechin, catechuin,* or *catechuic acid,* to which Etti gives the formula $C_{15}H_{18}O_8$, and *catechu red,* $C_{36}H_{34}O_{15}$, which is evidently the first anhydride of catechin. The *catechu tannic acid* is of the variety which precipitates iron of a greenish-black color, and differs from most of the other varieties in not yielding grape sugar when digested with diluted sulphuric acid. It is not, therefore, a glucoside. It precipitates gelatin, but not tartar emetic (Kane), and is not, like the tannic acid exposure of galls, converted into gallic acid by the access of the air. Catechu is almost wholly soluble in a large quantity of water, to which it imparts a brown color. The extractive or catechuic acid is much less soluble than the astringent principle, which may be almost entirely separated from it by the frequent application of small quantities of cold water. Boiling water dissolves it much more readily than cold, and deposits it of a reddish-brown color upon cooling. Both principles are readily dissolved by alcohol or proof spirit, and also by ether.

De Meyer affirms that the best method of detecting adulteration of catechu is to treat the suspected drug with ether. Catechu of good quality, after repeated treatment with ether, loses 53 per cent. of its weight, and the dried residue weighs only 47 per cent. of the catechu employed. If this be exceeded, the drug must be proportionately impure. (*J. P. C.,* June, 1870, 479.) A. Jossart (*J. P. A.,* 1881, 41) examined a catechu which was adulterated with from 60 to 65 per cent. of ferrous carbonate. For methods of assaying catechu and gambir, see Trimble's *The Tannins,* 43; also *Ph. Rev.,* 1897, 27. (See also *Gambir,* p. 507, and *U. S. D.,* 19th ed., p. 1436.)

Catechu is used for the same purposes and in the same proportions as *Gambir,* see page 507.

Dose, five to fifteen grains (0.3–1.0 Gm.).

CERA FLAVA. U.S., Br.

YELLOW WAX Cer. Flav. [Beeswax]

(cē'rą flā'vą)

"A product obtained by melting and purifying the honey-comb of the bee, *Apis mellifera,* Linné (Fam. *Apidæ*)." *U. S.* "Yellow Beeswax is obtained from the honeycomb of the Hive Bee, Apis mellifica, *Linn.,* and possibly other species of Apis." *Br.*

Yellow Beeswax; Cera Citrina; Beeswax; Cire Jaune, Cire d'Abeilles, *Fr.;* Cera Flava, *P. G.;* Gelbes Wachs, *G.;* Cera gialla, Cera vergine, *It.;* Cera amarilla, *Sp.*

The name *Apis mellifera* was given to the honey-bee of Linnæus in 1758, *Systema Naturæ,* 10th edition; subsequently (*Ibid.,* 12th edition, 1767), Linnæus changed the name to *mellifica,* but according to the established rules of scientific nomenclature the first name must hold, and the revisers of the United States Pharmacopœia were therefore correct in adopting it. It was at one time doubtful whether the wax which constitutes the walls of the honey-comb is elaborated or merely gathered by the insect. Huber, however, by feeding bees exclusively on honey and water, determined that under these circumstances wax is produced in the form of scales under the rings of the abdomen. But wax also exists in plants, bearing in this, as in other respects, a close analogy to the fixed oils. Besides the official species other bees are used as honey makers. The extremely vicious, blackish-brown *Apis fasciata* was kept by the ancient Egyptians on floating apiaries, which as the season progressed slowly drifted down the Nile, following the successive opening of the flowers. In Senegal, *Apis adansonii,* and in Southern Africa *Apis caffra* and *Apis scutellata* produce honey; while the *Apis unicolor* of Madagascar has been domesticated in that island and introduced into other parts of the world. In India honey is made in large quantities by *Apis dorsata* (the largest of known bees) (*Apis indica, Apis florea*). *India Wax* differs from official wax chiefly in its lower acid value. A wax is also produced in India by the so-called *Kota bees,* belonging to the genus *Melipona;* they are minute stingless insects, which furnish a sticky, dark-colored wax, resembling in physical and chemical characteristics the propolis of the honey bee rather than the true wax.

1. Cera Flava, or *Yellow Wax.*—This is obtained by slicing the comb taken from the hive, draining and afterwards expressing the honey, and melting the residue in boiling water, which is kept hot for some time in order to allow the impurities to separate and either subside or be dissolved by the water. When the liquid cools the wax concretes, and, having been removed and again melted in boiling water, is strained and poured into pans or other suitable vessels. The labor saving device is sometimes adopted of stretching a strainer of cheese cloth upon a hoop and wedging the latter down into the hot mixture below the level of the water; as this cools, the melted wax slowly rises through the cloth, and thus a perfectly clean cake of wax is formed on top on cooling. It is usually brought to market in round flat cakes of considerable thickness.

Properties.—Yellow wax is "a yellow to gray-brown solid, having an agreeable, honey-like odor, and a faint characteristic taste. It is somewhat brittle when cold, and when broken presents a dull, granular, not crystalline fracture. By the heat of the hand, it becomes plastic. Yellow wax is insoluble in water, sparingly soluble in cold alcohol; boiling alcohol dissolves the cerotic acid and a portion of the myricin. It is completely soluble in chloroform, ether, or in fixed or volatile oils; partly soluble in cold benzene or carbon disulphide, and completely soluble in these liquids at a temperature of from 25° to 30° C. (77° to 86° F.) Specific gravity: 0.950 to 0.960 at 25° C. (77° F.) determined as follows: Melt the wax at a low temperature and allow it to fall in separated drops from just above the surface into alcohol that has been warmed to from 45° to 50° C. (113°–122° F.). Allow the globules to remain in the alcohol until it has cooled spontaneously to room temperature (20° to 25° C.) (68° to 77° F.), then remove the wax and keep it at room temperature for 24 hours. Prepare a mixture of 4 volumes of alcohol and enough distilled water to make 10 volumes and allow it to stand until free from air bubbles. Moisten the globules of wax with distilled water, by means of a brush, and place them by means of forceps in the alcohol solution just prepared contained in a beaker. Then add alcohol or air-free distilled water as required to the mixture, kept at 25°C. (77° F.) until the globules of wax float or rest indifferently in the liquid, and finally determine the specific gravity of the alcoholic liquid. The figure thus obtained is the specific gravity of the wax examined. It melts between 62° and 65° C. (143.6° and 149° F.). Boil 1 Gm. of yellow wax for half an hour with 35 mils of an aqueous solution of sodium hydroxide (1 in 7), the volume being preserved by the occasional addition of distilled water; the wax separates on cooling without rendering the liquid opaque, and no precipitate is produced in the liquid after filtration through glass wool or asbestos, on the addition of hydrochloric acid in excess (*fats or fatty acids, Japan wax, or rosin*). Hydrochloric acid produces no precipitate in water which has been boiled with a portion of the wax (soap). Warm about 3 Gm. of yellow wax, accurately weighed, in a 200 mil flask with 25 mils of neutral dehydrated alcohol

until melted, then add 1 mil of phenolphthalein T.S. and titrate the mixture while warm with half-normal alcoholic potassium hydroxide V.S. to a faint pink color. The acid value so obtained is not less than 18 nor more than 24. Now add 25 mils of half-normal alcoholic potassium hydroxide V.S. and 50 mils of alcohol, boil the mixture for two hours under a reflux condenser and titrate the excess of the alkali with half-normal hydrochloric acid V.S. The ester value so obtained is not less than 72 nor more than 77." *U. S.*

"A yellowish-brown solid; somewhat brittle when cold, but becoming plastic by the heat of the hand. Agreeable, honey-like odor. Fracture granular, not crystalline. Soluble in *chloroform*, and in fixed and volatile oils. Specific gravity 0.958 to 0.970. Melting point 61° to 64° C. (141.8°–147.2° F.). *Refractive index* at 80° C. (176° F.) 1.4380 to 1.4420. When 5 grammes are boiled for ten minutes with 80 millilitres of an aqueous solution (1 in 10) of *sodium hydroxide*, the water lost by evaporation being made up, the resulting solution, cooled, and filtered through asbestos, does not become turbid when acidified with *hydrochloric acid* (absence of fats, fatty acids, Japan wax, resin). 5 grammes heated with 20 millilitres of *absolute alcohol*, and shaken until uniformly distributed, require for neutralisation at boiling temperature not less than 1.5 and not more than 2.0 millilitres of *N/1 alcoholic solution of potassium hydroxide, solution of phenolphthalein* being used as indicator (limits of free acid). Upon the further addition of 20 millilitres of *N/1 alcoholic solution of potassium hydroxide*, and on well boiling for one and a quarter hours in a flask to which a reflux condenser is attached, not less than 13.2 and not more than 13.8 millilitres of *N/1 solution of sulphuric acid* are required for neutralisation. When 5 grammes are boiled with a mixture of 15 millilitres of *N/1 alcoholic solution of potassium hydroxide* and 15 millilitres of *absolute alcohol* until completely saponified, the alcohol evaporated, the residue dissolved in 20 millilitres of *glycerin* on a water-bath and 80 millilitres of boiling *water* added, a clear or translucent solution is obtained (absence of ceresin, paraffin and other waxes). Not more than 1 per cent. is soluble in boiling *water* (limit of honey)." *Br.*

Dieterich examined hundreds of specimens annually, and found the wax to vary in sp. gr. from 0.963 to 0.966. He also determined the specific gravities of the following substances some of which are used to adulterate wax: white wax, 0.973; cera japonica, Japan wax, 0.975; ceresin, half white, 0.920; ozokerite, crude, 0.952; rosin, common, 1.108; cacao butter, 0.980 to 0.981; pure rosin, 1.045; beef suet, 0.952 to 0.953; yellow wax, 0.963 to 0.964; ceresin, white, 0.918; ceresin, yellow, 0.922; spermaceti, 0.960; French rosin, 1.104 to 1.105; paraffin, med. hard, 0.913 to 0.914; stearin, A No. 1, 0.971 to 0.972; mutton suet, 0.961.

Various adulterations have been practised, most of which may be readily detected. Meal, earth, and other insoluble substances are at the same time discovered and separated by melting and straining the wax. When the fracture is smooth and shining instead of being granular, the presence of rosin may be suspected. This is dissolved by cold alcohol, while the wax is left untouched. Yellow wax is frequently adulterated with a mixture of paraffin and rosin; such wax is usually translucent on the edges. For other adulterating substances used, and the modes of detecting them, see the remarks which follow on white wax.

Yellow wax is used chiefly as an ingredient of plasters and cerates.

2. Cera Alba, *Bleached Yellow Wax*, or *White Wax.*—The color of yellow wax is discharged by exposing it, with an extended surface, to the combined influence of air, light and moisture. The process of bleaching is carried on to a considerable extent in this country. The wax, previously melted, is made to fall in streams upon a revolving cylinder, kept constantly wet, upon which it concretes, forming thin ribbon-like layers. These, having been removed, are spread upon linen cloths stretched on frames and exposed to the air and light, care being taken to water and occasionally turn them. In a few days they are partially bleached; but, to deprive the wax completely of color, it is necessary to repeat the whole process once, if not oftener. When sufficiently white, it is melted and cast into small circular cakes. Yellow wax may also be decolorized by treatment with animal charcoal or with potassium permanganate, potassium dichromate and sulphuric acid, and hydrogen peroxide. White wax sometimes contains one or more free fatty acids, consequent probably upon the employment of alkalies in bleaching it, which render it an unfit ingredient in the unctuous preparations of certain salts. It may be deprived of these acids by means of alcohol.

Perfectly pure wax is white, shining, diaphanous in thin layers, inodorous, insipid, harder and less unctuous to the touch than the yellow, soft and ductile at 35° C. (95° F.) and fusible at 65° C. (149° F.), retaining its fluidity at a lower temperature. The U. S. Pharmacopœia describes it as "a yellowish-white solid somewhat translucent in thin layers, having a faint, characteristic odor; it is free from rancidity, and nearly tasteless. Specific gravity: 0.950 to 0.960 at 25° C. (77° F.), as determined by the method given under *Cera Flava.* It melts between 62° and 65° C. (143.6°–149° F.). The acid value is not less than 17 nor more than 23, and the ester value not less than 72 nor more than 79, as determined by the methods given under *Cera Flava.* In other respects White Wax has the characteristics of Yellow Wax and responds to the tests for identity and purity under *Cera Flava.*" *U. S.*

"Hard, nearly white, translucent cakes or

masses. 5 grammes heated with a mixture of 10 millilitres of *alcohol* (90 per cent.) and 10 millilitres of *absolute alcohol,* and shaken until evenly distributed, require for neutralisation at boiling temperature not less than 1.5 and not more than 2.2 millilitres of *N/1 alcoholic solution of potassium hydroxide, solution of phenolphthalein* being used as indicator (limits of free acid). In other respects White Beeswax responds to the tests described under '*Cera Flava.*'" *Br.*

By a great heat it is partly volatilized, partly decomposed; and, when flame is applied to its vapor, it takes fire and burns with a clear bright light. It is insoluble in water, and in cold alcohol or ether, but is slightly soluble in boiling alcohol and ether, which deposit it in a great measure upon cooling. The volatile and fixed oils dissolve it with facility, rosin readily unites with it by fusion, and soaps are formed by the action of sodium and potassium hydroxides. It is not affected by the acids at ordinary temperatures, but is converted into a black mass when boiled with concentrated sulphuric acid. Bleached wax contains, according to Lewy's analysis, 80.2 per cent. of carbon, 13.4 of hydrogen, and 6.4 of oxygen. It is a mixture of three different substances, which may be separated from one another by alcohol. —viz.: 1, *myricin,* insoluble in boiling alcohol, and consisting chiefly of myricyl palmitate ($C_{16}H_{31}O.OC_{30}H_{61}$),—that is, a compound of *palmitic acid,* $C_{16}H_{31}O.OH$, and *myricyl alcohol,* $C_{30}H_{61}OH$; 2, *cerotic acid,* $C_{27}H_{54}O_2$ (formerly called *cerin* when obtained only in an impure state), which is dissolved by boiling alcohol, but crystallizes out on cooling; 3, *cerolein,* which remains dissolved in the cold alcoholic liquid. This latter is probably a mixture of fatty acids, as indicated by its acid reaction. Schwalb (*Ann. Chem.,* ccxxiv, 225) found melissic acid and some unsaturated acids of the oleic series; also higher solid hydrocarbons of the saturated series, such as $C_{27}H_{56}$ and $C_{31}H_{64}$. Kebler states that the hydrocarbons in beeswax amount to from 12.72 to 13.78 per cent. (*A. J. P.,* 1893, 587.) T. Marie believes that cerotic acid, as ordinarily obtained, is a mixture of two distinct acids. He gives $C_{30}H_{60}O_2$ as the formula for melissic acid and $C_{25}H_{50}O_2$ for pure cerotic acid.

Wax has been variously adulterated. Heavy substances sink to the bottom of the vessel when the wax is melted. Starch, meal, and other insoluble substances remain behind when the wax is dissolved in oil of turpentine or petroleum benzin. Water, which is said to be sometimes fraudulently incorporated with it, by agitation when partially melted, is driven off by heat. Fatty substances render lime water turbid when agitated with it and allowed to stand. For the detection of stearin and stearic acid, Lebel dissolves the suspected wax in two parts of oil, beats the cerate thus formed with its weight of pure water, and then adds a few drops of solution of lead subacetate. If stearin be present, there will be an immediate decomposition, and the mixture will acquire an extraordinary solidity from the formation of lead stearate. (*J. P. C.,* 3e sér., xv.) Vogel proposes chloroform as a means of detecting the adulteration with fatty matters. That liquid dissolves only 25 per cent. of wax, but stearin and stearic acid completely. If, therefore, wax treated with 6 to 8 parts of chloroform loses more than one-quarter of its weight, it may be considered as impure. (*J. P. C.,* 3e sér., xvii.) Overbeck detects stearic acid by the abundant effervescence produced from the escape of carbon dioxide when a small portion of the suspected wax is boiled in a solution composed of one part of sodium carbonate and fifty of distilled water. (*P. J.,* xi, 128.) The best test for fats, fatty acids, or rosin is the pharmacopœial test of boiling with sodium hydroxide solution and testing the filtrate obtained after cooling. For the detection of rosin, cold alcohol is sufficient. It dissolves the rosin, and yields it on evaporation, attended with a very small portion of pure wax, which yields 2.4 per cent. to cold alcohol. (Ed. Davies, *A. J. P.,* 1870, p. 537.) F. Jean states that a few drops of sulphuric acid added to the melted wax adulterated with rosin, cause a red color, or, if only 1 per cent. be present, a green tint. (*A. J. P.,* 1881, p. 307.) *Japan wax* is said also to be largely employed for adulterating beeswax; so that sometimes but little of the product of the bee is to be found in the mixture. To detect Japan wax, Dullo boils together for a minute 10 Gm. of wax, 120 Gm. of water, and 1 Gm. of sodium hydroxide; if Japan wax be present, a soap will immediately form, which will slowly solidify on cooling. Beeswax does not saponify under these circumstances. (*J. P. C.,* 4e sér., i, 448.) Ceresin, a principle obtained from ozokerite (see Part II), is also employed as an adulterant, and is manufactured largely for that purpose in Vienna. It is only native paraffin, and of course answers to the tests for that substance. There are other less precise methods of detecting adulterations. Thus, spermaceti and lard render wax softer and less cohesive, of a smoother and less granular fracture, and of a different odor when heated. The melting point and specific gravity are lowered by tallow, suet, lard, and especially by paraffin. *Legrip's cereometer* is based upon the altered specific gravity of wax when adulterated. Anyone may apply this principle by making such a mixture of alcohol and water that pure wax will neither sink nor rise in it, but remain wherever placed. Adulterated wax would either float or sink in this liquid. The most valuable information, however, is obtained by the determination, according to Hübl's process, of the chemical constants—viz., acid value, ester value; and saponification value. In yellow wax the iodine value is also of use; in white wax the bleaching process has altered the bodies which absorb the iodine. See also *Chem. Ztg.,* 1893, 918; *Proc. A. Ph. A.,* 1894, 957; *D. C.,*

1898, 33; *Am. Drug.*, 1898, 97, and 1904, 103, 105.) According to G. Brehner (*Ztsch. Off. Ch.*, 1912, No. 5), who has investigated many samples of beeswax of normal and abnormal character, beeswax may be divided into three groups, according to source, as follows: (1) Ordinary normal beeswax in which the ratio of acid number to ester number is 1 : 3.6 to 1 : 4. (2) Beeswax of African origin in which the ratio is 1 : 3. (3) Beeswax of Indian origin in which the ratio is 1 : 12. A. Leijs (*J. P. C.*, 1912, No. 12) has made an extensive investigation of beeswax and *carnauba wax* by new methods, which he describes and which enable him with certainty to separate *paraffin, ceresin,* and *carnauba wax* readily from beeswax. The method depends upon the relative solubility of the substance in fuming hydrochloric acid.

Under the name of White Wax No. 2 or White Wax for technical use, there has been found in commerce a product put up in exact imitation of white beeswax, and consisting of over 90 per cent. of paraffin.

Vegetable Wax.—Many vegetable products contain wax. It exists in the pollen of numerous plants, and forms the bloom or glaucous powder which covers certain fruits, and the coating of varnish with which leaves are sometimes supplied. In some plants it is so abundant as to be profitably extracted for use. Such is the *Ceroxylon andicolum* Humb., a lofty palm growing in the South American Andes. Upon the trunk of this tree, in the rings left by the fall of the leaves, is a coating of wax-like matter, about one-sixth of an inch thick, which is removed by the natives and employed in the manufacture of tapers. It contains, according to Vauquelin, two-thirds of a resinous substance and one-third of pure wax. Two kinds of wax are collected in Brazil, one called *carnauba,* from the leaves of the *Copernicia cerifera,* a palm, which forms large forests in the provinces of Ceara, the other *ocuba,* from the fruit of a shrub of the province of Para. (*J. P. C.*, 3e sér., v, 154.)

Carnauba Wax is collected by cutting out the leaf buds of *Copernicia cerifera* (Arruda) Mart. (fam. *Palmaceæ*), commonly called the *Brazilian Wax Palm,* drying and beating them, and melting the powder thus detached, in water. H. Stürke has stated as the result of an investigation that carnauba wax contains: a hydrocarbon, melting at 59° C. (138.2° F.); an alcohol, $C_{27}H_{55}OH$, melting at 76° C. (168.8° F.); myricyl alcohol, $C_{30}H_{61}.OH$, melting at 85.5° C. (185.9° F.); a diatomic alcohol, $C_{25}H_{50}.(OH)_2$, melting at 103.5° to 103.8° C. (218.3°–218.8° F.); an acid, $C_{24}H_{48}O_2$, isomeric with lignocerotic acid, melting at 72.5° C. (162.5° F.); an acid, $C_{27}H_{54}O_2$, isomeric with cerotic acid, melting at 79° C. (174.2° F.) and an acid, or rather the lactone (anhydride) of an acid, $C_{19}H_{38}\begin{cases} CH_2OH \\ COOH \end{cases}$, melting at 103.5° C. (218.3° F.), from which an acid, $C_{19}H_{38}(COOH)_2$, melting at 90° C. (194° F.) has been prepared. (Schaedler, *Technol. der Fette und Oele,* 2te Auf., p. 884.) It is hard, brittle, and buff-colored, yellow, or greenish, resembling the resins more than wax, and melts at 84° C. (183.2° F.) which is much higher than the fusing point of other kinds of vegetable wax. It takes a fine polish when rubbed with any soft material, does not receive impressions from the finger at the natural temperature of the hand, and is adapted for polishing furniture, either alone or mixed with wax. 2,000,000 pounds of it are said to be annually produced in Brazil, where it is largely used, mixed with tallow, in making candles, etc. (See also *P. J.*, 1904, 246.) (See also *Carnauba Root,* Part II.)

A form of vegetable wax sometimes seen in this country is that derived from *Myrica cerifera* L., and commonly called *myrtle wax.* The *wax myrtle* is an aromatic shrub, from one to twelve feet high, growing in the United States, from New England to Louisiana, and flourishing especially on the sea coast. The fruit, which grows in clusters closely attached to the stems and branches, is small, globular, and covered with a whitish coat of wax, which may be separated for use. Other parts of the plant are said to possess medicinal virtues. The bark of the root is acrid and astringent, and in large doses emetic, and has been popularly employed in jaundice. The process for collecting the wax is simple. The berries are boiled in water, and the wax, melting and floating on the surface, is either skimmed off and strained, or allowed to concrete as the liquor cools, and then removed. To render it pure, it is again melted and strained, and cast into large cakes. It is collected in New Jersey, North Carolina, and New England, and particularly in Rhode Island.

China wax, called *pe-la* by the Chinese, resembles spermaceti in whiteness and crystalline appearance, but is distinguished by greater hardness and friability and a somewhat fibrous fracture. It melts at about 83° C. (181.4° F.), is very slightly soluble in alcohol or ether, is insoluble in cold oil of turpentine and rectified petroleum, but is dissolved with the aid of heat, and is very soluble in benzene. These solubilities distinguish it from spermaceti. (*P. J.*, xiv, 9.) It was formerly supposed to be of vegetable origin, but has been ascertained to be the product of an insect, *Coccus ceriferus,* deposited on the twigs of the Chinese Ash, *Fraxinus Chinensis* (Roxburgh), and investing them closely; the insect becomes embedded in a waxy material, which is scraped off with the insects, and constitutes the crude wax. It is purified by melting and straining. It is one of the chief industries in the province of S'zchuan, second only in importance to the silk culture. It is used over the entire Empire for candles and as medicine. (For details of its collection see *U. S. D.*, 19th ed., p. 307; also *P. J.*, 1885, xv.)

Under the name of *Ocotilla wax,* Helen Abbott Michael described (*A. J. P.*, Feb., 1885) a vegetable wax which she obtained from the bark

of *Fouquiera splendens,* and believed to be a new variety. A wax which is said to be used, under the name of *Arbol de la Cera,* in Mexico not only for domestic purposes, but also as a remedy in diarrhea and jaundice, is that obtained by boiling the fruit of the *Myrica jalapensis* in water. It is greenish or yellow, more brittle and unctuous than beeswax, has a feeble odor, a slightly bitter taste, and a density nearly equal to that of water, and melts at 43° C. (109.4° F.); but on exposure the fusing point rises to 47.5° C. (117.5° F.). It is wholly soluble in boiling ether, insoluble in water, sparingly soluble in cold alcohol, and dissolves in twenty parts of boiling alcohol, depositing the greater part on cooling; alkalies saponify it readily. (*A. J. P.,* xv, 339, 1885.)

Pisang Wax from *Ficus cerifera,* according to Greshoff and Sack, occurs in white crystalline cakes, having the sp. gr. 0.963 to 0.970 at 15° C. (59° F.), and melting at 79° to 81° C. (174.2°–177.8° F.). It is very sparingly soluble in ethyl alcohol, even when boiling, but readily soluble in boiling oil of turpentine, amyl alcohol, and carbon disulphide. Its acid number is 2 to 3, its saponification number 109. *Pisang-cerylic acid,* obtained by saponification, melts at 71° C. (159.8° F.), and has the composition $C_{24}H_{48}O_2$; while *pisang-cerylic alcohol,* which was also isolated, melts at 78° C. (172.3° F.), and has the formula $C_{13}H_{18}O$.

Gondang Wax occurs in brown pieces which are yellowish internally and have a sp. gr. of 1.015. In distinction from pisang wax, gondang wax is soluble in all the usual solvents at a boiling temperature, and it may be almost completely dissolved by prolonged boiling with ethyl alcohol, being however again deposited on cooling. Gondang wax purified in this way melted at 61° C. (141.8° F.), and yielded *fico-cerylic acid* on saponification, which has the formula $C_{13}H_{26}O_2$, and melts at 57° C. (134.6° F.), while *fico-cerylic alcohol* has the formula $C_{17}H_{28}O$, and melts at about 198° C. (388.3° F.). In its general character gondang wax is intermediate between wax and caoutchouc. (*Ph. Ztg.,* 1901, 563.)

Japanese Wax has been imported into Europe in considerable quantities, either directly from Japan, or through the Chinese ports. It is obtained from the berries of the *Rhus succedaneum* of Linnæus, and in small amount from the *R. sylvestris* and *R. vernicifera,* or lacquer plant. The partially dried berries are crushed, winnowed, steamed, placed in hemp cloth bags, steamed again, and pressed in a wooden wedge press. They yield about 15 per cent. of a coarse greenish tallowy mass. It has come in two forms, the one, as originally distinguished by Hanbury, of circular cakes, about four inches in diameter, and an inch thick, flat on one side and somewhat convex on the other; the second, as brought directly from Japan, of large rectangular blocks weighing, it may be, as much as 1 picul (133⅓ lbs.) which are packed in chests. It bears a considerable resemblance to purified beeswax, but is not quite so white, having a slightly yellowish tint, is softer, more friable, and has a somewhat rancid odor and taste. Its melting point is below that of wax, varying from 42° C. (107.6° F.) to 55° C. (131° F.). It is much more soluble in alcohol than is beeswax, is saponifiable with the alkalies, and is in the main a glyceride of palmitic acid with smaller amounts of the glycerides of stearic and arachidic acids. It has been employed in the preparation of candles, which yield as brilliant light as those made of common wax. It has been found useful in the preparation of cerates, etc. From Roucher's experiments it appears that there are two melting points of this wax, one corresponding closely with Procter's results, while the same wax rapidly heated to a point above that of fusion and then allowed to cool, if plunged into water at 42° C. (107.6° F.), melts into a transparent liquid; consequently melting at a point 12° C. below its freezing point in the ordinary state, which was 54° C.; the two temperatures being about equivalent in Fahrenheit's scale to 107° and 129°. (*P. J.,* Aug., 1872.)

Myrtle wax is of a pale grayish-green color, somewhat diaphanous, more brittle and unctuous to the touch than beeswax, of a feeble odor, and a slightly bitterish taste. It is about as heavy as water, and melts, according to G. E. Moore, at from 46.6° to 48.8° C. (116°–120° F.). It is insoluble in water, scarcely soluble in cold alcohol, soluble, excepting about 13 per cent., in twenty parts of boiling alcohol, which deposits the greater portion on cooling, soluble also in boiling ether, and slightly so in oil of turpentine. It is readily saponifiable with the alkalies. Myrtle wax is a mixture of glycerides and not a true wax. This variety of wax has been popularly employed in the United States as a remedy for *dysentery;* in which disease Fahnestock gave the powdered wax in doses of a teaspoonful frequently repeated, with alleged advantage. (*Am. J. M. S.,* ii, 313.) It is occasionally substituted by apothecaries for beeswax in the formation of plasters, and is used in the preparation of tapers and candles. It is somewhat fragrant when burning, but emits a less brilliant light than common lamp oil.

Uses.—Wax has little effect upon the system. Under the impression that it sheathed the inflamed mucous membrane of the bowels, it was formerly prescribed in *diarrhea* and *dysentery;* and it is mentioned by Dioscorides as a remedy in the latter complaint; but at the present time, we suppose, no one would think of employing wax for such purposes. Its sole use in modern medicine is in the formation of ointments, cerates, plasters, suppositories, and surgical dressings, etc.; in which it acts mechanically, either giving stiffness or serving to protect from water. It is an ingredient in almost all the official cerates, which owe to it their general title.

CERATA.

CERATES

(cę-rā'tą)

Cérats, Céréolés, Elæocéréolés, *Fr.;* **Cerate, Wachssalben,** *G.*

These are unctuous substances consisting of oil or lard, mixed with wax, spermaceti, or rosin, to which various medicaments are frequently added. Their consistence, which is intermediate between that of ointments and that of plasters, is such that they may be spread at ordinary temperatures upon linen or leather, by means of a spatula, and do not melt or run when applied to the skin. In preparing them, care should always be taken to select the oil or lard perfectly free from rancidity. In reference to the wax, too, there would seem to be a choice, as experience has shown that cerates mades with yellow wax keep longer unchanged than those made with white or bleached wax, probably because there is in yellow wax some principle which corrects the tendency of fatty matters to become rancid. The liquefaction should be effected by a very gentle heat, which may be applied by means of a water bath, and during the refrigeration the mixture should be well stirred, and the portions which solidify on the sides of the vessel should be made to mix again with the liquid portion, until the whole assumes the proper consistence, or, as some prefer, the melted cerate is allowed to cool quickly without stirring. When a large quantity is prepared, the mortar or other vessel into which the mixture may be poured for cooling should be previously heated by means of boiling water. It has been proposed to substitute paraffin for wax in the preparation of the cerates, but the great tendency to produce granulation in the finished cerate has largely prevented its use.

It is, we think, unfortunate that this class of preparations has been abandoned in the British Pharmacopœia, the several cerates having been rejected, or transferred to the class of ointments. Independently of the connection between the name and one of the characteristic constituents of the cerates, there is ground for difference between them and the ointments in their consistence, that of the cerates being such as to render them especially suitable for spreading on linen, while that of ointments is peculiarly adapted to inunction. W. H. Mielcke (*Ph. Cb.*, 1881, Nos. 20, 21) proposes a class of preparations, to which he has given the name "*Steatins*," "*Steatinum*." These are of about the consistence of cerates, of varied composition, and contain usually a considerable portion of tallow. The *Steatinum Iodoformi* offers a fair specimen of the class. "Take of mutton tallow 18 parts, expressed oil of nutmeg 2 parts, iodoform, in fine powder, 1 part. Melt the tallow and add the other ingredients." For other formulas, see the N. F. IV (Part III), and *A. J. P.*, 1881, p. 404.

CERATUM. U. S.

CERATE Cerat. [Simple Cerate]

(cę-rā'tŭm)

Ceratum Adipis, *U. S.* 1860; **Ceratum Simplex,** *U. S.* 1850; **Cérat Simple,** *Fr. Cod.;* **Unguentum cereum,** *P. G.;* **Einfaches Cerat, Wachssalbe,** *G.;* **Cerato simple,** *Sp.*

"White Wax, *three hundred grammes* [or 10 ounces av., 255 grains]; Benzoinated Lard, *seven hundred grammes* [or 24 ounces av., 303 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the white wax, by the heat of a water bath, add the benzoinated lard, continue the heat until the mixture is liquefied, strain if necessary, and stir constantly until it congeals. For use in southern latitudes, and during the heated season in other localities, *fifty grammes* [or 1 ounce av., 334 grains] of the benzoinated lard (or more, if necessary) may be replaced by an equal quantity of white wax." *U. S.*

In the U. S. Pharmacopœia (VIII) 20 per cent. of white petrolatum, and 50 per cent. of benzoinated lard were directed in place of the 70 per cent. of lard used in the U. S. P. 1890 process. In the present official cerate the white petrolatum was omitted. In the preparation of cerate, peculiar care should be taken that the oleaginous ingredient be entirely free from rancidity, and that the heat employed be not sufficient to produce the slightest decomposition, for the value of the preparation depends on its perfect blandness. To avoid change, it should be put up in small jars, and covered closely with tin foil so as to exclude the air. It is used for dressing *blisters, wounds,* etc., in all cases in which the object is to prevent the contact of air and preserve the moisture of the part and at the same time to avoid all irritation. It is sometimes improperly employed as the vehicle of substances to be applied by inunction. For this purpose benzoinated lard should be used in winter, and simple ointment in summer, the cerate having too firm a consistence. George W. Sloan recommended the use of simple cerate as a pill excipient for certain oxidizable substances and special uses. (*Proc. A. Ph. A.*, 1884.)

CERATUM CANTHARIDIS. U. S.

CANTHARIDES CERATE Cerat. Canthar. [Blistering Cerate]

(cę-rā'tŭm cąn-thăr'į-dīs)

Emplastrum Cantharidini, *Br.;* **Cantharides Plaster; Emplastrum Epispasticum, s. Vesicatorium, s. Vesicans, Emplastrum Lyttæ; Blistering Cerate or Plaster; Emplâtre Vesicatoire,** *Fr. Cod.;* **Pommade Epispastique, Emplâtre de Cantharides,** *Fr.;* **Emplastrum Cantharidum Ordinarium,** *P. G.;* **Spanischfliegen Pflaster, Blasenpflaster,** *G.;* **Pomata di cantaridi,** *It.;* **Unguento de cantharidas,** *Sp.*

* "Cantharides, in No. 60 powder, *three hundred and fifty grammes* [or 12 ounces av., 151

grains; Glacial Acetic Acid, *twenty-five mils* [or 406 minims]; Oil of Turpentine, *one hundred and fifty mils* [or 5 fluidounces, 35 minims]; Yellow Wax, *one hundred and seventy-five grammes* [or 5 ounces av., 513 grains]; Rosin, *one hundred and seventy-five grammes* [or 5 ounces av., 513 grains]; Benzoinated Lard, *two hundred grammes* [or 7 ounces av., 24 grains], to make *one thousand grammes.* Moisten the cantharides with the oil of turpentine and the glacial acetic acid, previously mixed, and set the mixture aside in a well-covered container, in a warm place, for forty-eight hours. Melt together the rosin, yellow wax, and benzoinated lard; strain the mixture through muslin, add the macerated cantharides and keep the mixture in a liquid condition by heating it on a water bath with occasional stirring, until it is reduced in weight to *one thousand grammes.* Then withdraw the heat and stir the Cerate until it becomes firm." *U. S.*

This is the commonly called *blistering plaster.* As it can be readily spread without the aid of heat, it is properly a cerate, and is, therefore, correctly named in the U. S. Pharmacopœia. The U. S. P. IX has recognized a plaster in which this cerate is spread upon fabric, while the British Pharmacopœia contains a preparation similar to the U. S. cerate, under the title *Emplastrum Cantharidini.* In the Br., however, cantharidin is used instead of cantharides. (See also *Emplastrum Cantharidis.*)

"Cantharidin, 2 *grammes;* Chloroform, 100 *millilitres;* Yellow Beeswax, 450 *grammes;* Wool Fat sufficient to produce 1000 *grammes.* Dissolve the Cantharidin in the Chloroform by the aid of heat, add to the other ingredients previously melted on a water-bath, and stir until cold. This Plaster contains 0.2 per cent. of Cantharidin, which is approximately the proportion contained in the Emplastrum Cantharidis of the British Pharmacopœia, 1898." *Br.*

The process for the cerate, now official, differs from that of previous Pharmacopœias in the use of glacial acetic acid, and oil of turpentine; the previous digestion of the cantharides with this mixed solvent has for its object the softening of the drug and extraction of the cantharidin; the present cerate is somewhat firmer in consistence than that made by the U. S. P., 1890.

There can be no question of the advantage of retaining the cantharides in contact with hot of the cantharidin.

From the experiments of Donovan, and those of Procter (*A. J. P.*, xiii, 302 and xxiv, 296), it may be inferred that the vesicating principle of Spanish flies is not injured or dissipated by a heat under 148.8° C. (300° F.), and that a limited elevated temperature, instead of being hurtful, is positively advantageous in the preparation of the cerate. The cantharidin is thus more thoroughly dissolved by the oleaginous matter, and consequently brought more efficiently into contact with the skin, than when retained in the interior of the tissue of the fly. Another advantage, stated by Donovan, is that the moisture usually existing to a certain extent in all the ingredients of the cerate is thus dissipated, and the preparation is less apt to become mouldy, or otherwise to undergo decomposition. Donovan recommends that, as soon as the other ingredients are melted, the powdered flies should be added, and the mixture stirred until the heat is shown by a thermometer to have risen to 121.1° C. (250° F.), when the vessel is to be removed from the fire, and the mixture stirred constantly until cool. At the heat mentioned, ebullition takes place in consequence of the escape of the moisture contained in the materials. In the cerate thus prepared, the active matter has been dissolved by the lard, and the powder may be separated, if deemed advisable, by straining the mixture before it solidifies. Care should be taken that the temperature be not so high as to decompose the ingredients; and it would be better to keep it within 100° C. (212° F.), by means of a water bath, as in the U. S. process, than to incur any risk from its excess. Violent irritation and even vesication of the face of the operator are stated to have resulted from exposure to the vapors of the liquid, at a temperature of 121.1° C. (250° F.). (*P. J.*, ii, 391.) From an experiment, however, of Procter, it appears that, though cantharidin begins to volatilize slightly at 121.1° C. (250° F.), and rapidly rises in vapor and sublimes at from 205.5° C. to 211.1° C. (402° F.–412° F.), yet it is not decomposed unless by increasing the heat considerably above the last-mentioned point. (*A. J. P.*, xxiv, 296 and 298.) Dieterich states that the activity is greatly increased by the use of acid in the manufacture. Thus, for every 250 Gm. of powdered flies used he adds to the melted mass 1 Gm. sulphuric acid and 10 Gm. alcohol (90 per cent.), keeps the mass for two hours at 70° C. (158° F.), and finally adds 2 Gm. barium carbonate rubbed up with 6 Gm. alcohol. (*Ph. Centralh.*, 1892, 425.) It is desirable that the flies should be very finely pulverized. Coarsely powdered cantharides should not be used, because of the imperfect and unequal distribution of the vesicating agent. Powdered euphorbium is said to be sometimes fraudulently added.

Uses.—The cerate will raise a blister in ordinary conditions of the system, if the flies are good, and not injured in the preparation. It should be spread preferably on soft leather, though linen or even paper will answer the purpose when leather is not to be had. The official directions for this plaster mention the use of the commercial rosin plaster, but further state that it may be spread upon any other suitable material. Heat is not a requisite, and should not be employed in spreading the cerate. Some operators sprinkle powdered flies upon the surface of the plaster, press them lightly with a roller, and then shake off the portion which has not adhered; but, if the flies

originally employed were good, this addition is superfluous. The practice of applying over the surface with a brush an ethereal tincture of cantharides, which leaves a thin coating of extract, renders the preparation more certain.

Previous to the application of the plaster, the skin should be moistened with warm vinegar or other liquid. In adults, when the full action of the flies is desired, and the object is to produce a permanent effect, the application should be continued for eight hours, and on the scalp for twelve hours. In very delicate persons, however, or those subject to strangury, or upon parts of a loose texture, or when the object is merely to produce a blister to be healed as quickly as possible, the plaster should remain no longer than is necessary for the production of full redness of the skin, which generally occurs in five or six hours, or even in a shorter time. It should then be removed, and followed by a flaxseed poultice, or some other emollient dressing, under which the cuticle rises, and a full blister is usually produced. By this management the patient will generally escape strangury, and the blister will very quickly heal after the discharge of the serum. In young children, cantharides sometimes produce alarming and even fatal ulceration, if too long applied, and from two to four hours are usually sufficient for any desirable purpose. When the head, or other hairy part, is to be blistered, an interval of ten or twelve hours should, if possible, be allowed between the shaving of the part and the application of the plaster, so that the abrasions may heal, and some impediment be offered to the absorption of the cantharidin. After the blister has been formed, it should be opened at the most depending parts, and, the cuticle being allowed to remain, should be dressed with simple cerate; but, if it be desirable to maintain the discharge for a short time, rosin cerate should be used, and the cuticle removed if it can be done without inconvenience. When it is wished that the blistered surface should heal as soon as possible, the application of an antiseptic desiccant powder, as iodoform or thymol iodide, is advantageous.

Various preparations of cantharides have been proposed and employed as substitutes for the cerate. They consist for the most part of cantharidin, more or less pure, either dissolved in olive oil, and applied to the skin by means of a piece of paper saturated with it, or incorporated with wax and spread in a very thin layer upon fine waxed cloth, silk, or paper, constituting *blistering cloth, blistering paper, vesicating taffeta,* etc. (See *Emplastrum Cantharidis.*) The advantages of these preparations are that they occupy less space, are more portable, and, being very pliable, are more easily adapted to irregularities of the surface. Absolutely pure cantharidin is expensive and not requisite, as extracts of cantharides, made with ether, alcohol, or boiling water, will answer every purpose. Henry and Guibourt give the following formula. Digest powdered cantharides in ether, distil off the ether, evaporate the residue by means of a salt water bath, until ebullition ceases, melt the mass which remains, with twice its weight of wax, and spread the mixture upon waxed cloth. The *waxed cloth* may be prepared by spreading upon linen or muslin a mixture composed of 8 parts of white wax, 4 of olive oil, and 1 of turpentine, melted together. An extract of cantharides of a buttery consistence, said to act very efficiently when applied by means of paper greased with it, is prepared by digesting 4 parts of flies with one part of strong acetic acid and 16 of alcohol, straining, filtering, and evaporating at a moderate heat. *A cerate of the extract of cantharides* was formerly official (see *U. S. D.,* 18th ed., p. 358.)

A preparation which received the favorable report of a committee of the Society of Pharmacy, at Paris, is the following, proposed by Dubuisson. Four parts of a hydro-alcoholic extract of the flies, made by maceration, are mixed with an aqueous solution of one part of pure gelatin, so as to obtain a solution of suitable consistence, which is then applied upon a piece of stretched waxed cloth, care being taken that the strokes of the brush should always have the same direction. When the first layer has dried, a second and a third are to be applied in the same manner. The gelatin renders the plaster more adhesive and gives consistence. The hydro-alcoholic extract is preferred to the alcoholic, because it contains less of the green oil, which does not readily mix with the other ingredients. The committee, however, preferred the aqueous extract, as cheaper and more active. This taffeta has been tried, and found to raise blisters in four hours. (*J. P. C.,* 3e sér., viii, 67.) For very speedy vesication, an infusion of the flies in strong acetic acid is sometimes employed. None of these preparations are likely to supersede the cerate, but the demand for them was met by introducing into the Pharmacopœia *Collodium Cantharidatum.*

Off. Prep.—Emplastrum Cantharidis, *U. S.*

CERATUM RESINÆ. U. S. (Br.)

ROSIN CERATE Cerat. Res. [Basilicon Ointment]

(cę-rā'tŭm rę-sī'næ)

Unguentum Resinæ, *Br.;* Resin Ointment, Ointment of Resin, Unguentum Basilicum; Unguentum Tetrapharmacum; Resin Ointment, Resin Cerate; Onguent Basilicum, *Fr. Cod.;* Cérat de Résine Anglais, *Fr.;* Harzcerat, Harzsalbe, Königsalbe, Zugsalbe, *G.*

℞ "Rosin, *three hundred and fifty grammes* [or 12 ounces av., 151 grains]; Yellow Wax, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Lard, *five hundred grammes* [or 17 ounces av., 279 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the rosin, add the yellow wax and the lard, and continue the heat until liquefied, then strain the liquid through muslin, and allow it to congeal with occasional stirring. In cold weather *five hundred and thirty*

grammes [or 18 ounces av., 304 grains] of lard, and *one hundred and twenty grammes* [or 4 ounces av., 102 grains] of yellow wax may be used." *U. S.*

"Resin, 26 *grammes;* Yellow Beeswax, 26 *grammes;* Olive Oil, 26 *grammes;* Prepared Lard, 22 *grammes.* Melt together; strain; stir until cold. In India, Prepared Suet (Sevum Præparatum) should be employed instead of Prepared Lard in making this Ointment." *Br.*

The U. S. preparation does not differ greatly from that formerly official except that occasional stirring while congealing is directed; the U. S. P. 1890 process forbade stirring. The British process (1898) discards the simple ointment and almond oil previously used (1885), and substitutes lard and olive oil. *Ceratum Resinæ Composition*—Compound rosin cerate. *Deshler's Salve* was dropped from the U. S. P. IX. It is retained in the N. F. IV (see Part III). It is made from rosin, yellow wax, prepared suet, turpentine (white) and linseed oil, and is used for the same purposes as Ceratum Resinæ. Rosin cerate, commonly called *basilicon ointment,* is much used as a gently stimulating application to *blistered surfaces, indolent ulcers, burns, scalds,* and *chilblains.* We have found no application more effectual in disposing the *ulcers* which follow *burns* to heal.

Off. Prep.—Linimentum Terebinthinæ, *U. S.*

CERII OXALAS. U. S.

CERIUM OXALATE Cerii Oxal. [Cerous Oxalate]

(cē'rĭ-ī ŏx'ą-lās)

"A mixture of the oxalates of cerium, didymium, lanthanum, and other associated elements." *U. S.*

Oxalate of Cerium; Cerium Oxalicum, Oxalas Cericus; Oxalate de Cérium, *Fr.;* Oxalsaures Ceroxydul, Cerium Oxalat, Ceroxalat, *G.*

Cerium = 140.25, is a metal which was discovered in 1803 by Berzelius and Hisinger, and about the same time by Klaproth, who, however, described it as an earth. By the two former chemists it was recognized as a metal, and named cerium in honor of the goddess Ceres. It was obtained from a Swedish mineral, formerly from its great weight called *heavy stone of Bastnas* (*Bastnas Schwerstein*), but now named *cerite,* after the metal extracted from it. Besides cerite, it has been found in several other minerals, as *gadolinite, orthite,* and *monazite,* etc. It is not easy to obtain it pure in the metallic state, as its oxides and salts are difficult of reduction. Berzelius describes cerium as in the form of pulverulent masses, of a deep chocolate-brown color which exhibit, however, under the burnisher a metallic appearance and a dark gray color. Hildebrand and Norton have since prepared it in large quantity by the electrolysis of its chloride. It is a poor conductor of electricity. Sp. gr. 6.92 at 25° C. (77° F.), melting point 645° C. (1193° F.). Heated in the air it takes fire before the point of ignition, and burns vividly, passing to the state of peroxide. At ordinary temperatures it is oxidized in a moist atmosphere, giving out a strong and disagreeable odor. In water, especially when moderately heated, it rapidly oxidizes, with the evolution of hydrogen and the water does not become alkaline. There are two cerium oxides, Ce_2O_3 and CeO_2. Sulphur and phosphorus combine with it. Of its compounds two only have been introduced into medicine, the nitrate and the oxalate.

Cerium oxalate may be obtained from cerite, and F. F. Mayer gave a process for the purpose, of which the following is an outline. The mineral consists of cerium, lanthanum, and didymium silicates, with numerous other substances in smaller proportion, the cerium oxide constituting about 39 per cent. of the whole. The powdered mineral is made into a paste with sulphuric acid, and then heated over a lamp until the mass ceases to swell and no longer absorbs sulphuric acid very cautiously added. Upon the cooling of the mass, it is powdered, and exposed in a crucible to the heat of an anthracite fire until it assumes a pale brownish-red color. It is now lixiviated first with hot water and then with nitric acid, and the solution treated with hydrogen sulphide in order to get rid of various metals by precipitation. To the clear liquid some hydrochloric acid is first added, and then a solution of oxalic acid, the former of which holds in solution the calcium oxalate produced, the latter throws down cerium oxalates and oxalates of other metals. The precipitate, having been washed with warm water, is formed into a paste with a quantity of magnesium carbonate equal to half that of the mineral employed; and the paste is dried on porous fire brick, finely powdered, and calcined until it becomes of a cinnamon color. It now contains all of the cerium in the form of ceroso-ceric oxide. To separate this the mass is treated with an excess of nitric acid, the solution evaporated to get rid of the excess of acid, then diluted with warm water, and lastly poured into a vessel containing boiling water acidulated with a little more than half of one per cent. of sulphuric acid. A yellow precipitate of basic cerium sulphate is formed, while a little of the neutral sulphate, and all the lanthanum and didymium, remain dissolved. The precipitate is now dissolved in stronger sulphuric acid, the solution digested with a few crystals of sodium thiosulphate, in order to reduce the ceroso-ceric oxide to cerous oxide, and the liquid, having been filtered, is treated with solution of oxalic acid, which causes a precipitate of cerium oxalate. This is washed with warm water, and dried.

The cerium compounds were formerly obtained chiefly from cerite, which occurs in considerable amounts in Sweden, and affords at least 50 per cent. of *cerium oxide.* The thorium salts were obtained from the mineral *thorite,* which is found in Norway, and contains about 60 to 70 per cent. of its peculiar earth. According to O. N. Witt, it was soon found that the supplies of thorite were not sufficient to even approximately meet the de-

mand for thorium salts required for the incandescent gas mantle industry. A new source of supply was therefore sought for, and this has been found in the mineral monazite, which occurs in considerable quantities in North Carolina and in the Province of Bahia, in Brazil. It is from the latter source that the German industries now chiefly draw their supplies. Monazite is a cerous phosphate, in which a portion of the cerium is replaced by the other cerite earths. The thorium earth is not an integral constituent of the mineral, and, although quite regularly admixed with it, its amount varies within very broad limits. It is further stated by Witt that the monazite from Bahia contains at the most from 5 to 6 per cent. of thorium earth, while the earths of the cerite group amount to from 50 to 60 per cent. or more, of which about one-half is cerium itself. The occurrence of these two earths in nature is therefore in inverse proportion to the requirements for industrial purposes. As enormous quantities of monazite have to be worked up in order to obtain the necessary supplies of thorium salts, and as only a very small proportion of the cerite earths which are obtained at the same time can be utilized in the form of cerium nitrate, it is evident that these must accumulate in considerable amounts. It has thus become an important problem, upon which technical chemists have been engaged for some time, to devise a practical method for the separation of the cerite earths, with the hope that they might then find some industrial applications for which the complex mixtures now available are not adapted. From the existing conditions of this industry, as briefly outlined, it may be inferred that the cerium oxalate of commerce, which, although used medicinally, likewise consists of such a complex mixture of the oxalates of cerium, lanthanum, and didymium, is at present more or less a by-product in the manufacture of thorium salts. See Power and Shedden, on the Composition and Determination of Cerium Oxalate. (*J. Soc. Chem. Ind.*, xix, No. 7; also *Ph. Ztg.*, 1902, 297.)

Metallic cerium has come into prominence recently as an essential constituent of a class of alloys known as *pyrophoric alloys*, of which ferro-cerium is the commonest and cheapest. These are used to set fire to inflammable gases, in what are called mechanical or automatic gas lighters, by means of a shower of bright sparks which is emitted when one of these alloys is filed. This property of certain alloys of cerium and other metals was discovered in 1903 by Welsbach, who found the best results to follow the use of a combination carrying about 65 per cent. of cerium earth metals and 35 per cent. of iron. Other alloys have also been experimented with, the one with zinc being used in practice in connection with automatic lighting mine lamps. The greatest pyrophoric power of any alloy yet experimented with was found to be developed in a platinum cerium alloy, but, of course, this is too expensive for practical use. Various theories have been advanced to explain the reason for the spark producing power of these alloys, it being claimed that the property is due to the presence of nitrides, hydrides, etc. None of these theories have been substantiated and the cause remains a mystery.

Properties.—It is officially described as "a fine white or slightly pink powder, without odor or taste; permanent in the air. It is insoluble in water, alcohol, ether, and in solutions of potassium or sodium hydroxide; insoluble in cold, diluted sulphuric or hydrochloric acid, but dissolved by these acids when heated. When heated to redness it is decomposed, leaving not less than 47 per cent. of a reddish-brown residue. Boil Cerium Oxalate with potassium hydroxide T.S.; an insoluble precipitate of white hydroxides is produced. Filter and supersaturate the filtrate with acetic acid; the addition of calcium chloride T.S. produces a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid. From a solution of Cerium Oxalate in diluted hydrochloric or sulphuric acid, potassium hydroxide T.S., added in slight excess, precipitates white hydroxides, which do not redissolve in a larger excess of the reagent, but gradually turn yellow in contact with air. Ammonium carbonate T.S. added in slight excess to a similar acid solution produces a white precipitate of the mixed carbonates of cerium and associated elements, which is somewhat soluble in a larger excess of the reagent. Dissolve 0.1 Gm. of Cerium Oxalate in 1 mil of sulphuric acid and add 2 mils of potassium sulphate T.S.; small, colorless crystals of double sulphates of potassium and the rare-earth elements in the mixture are deposited after some time. No effervescence occurs when Cerium Oxalate is dissolved in diluted hydrochloric acid (*carbonates*). A solution of Cerium Oxalate (1 in 50) in diluted hydrochloric acid does not respond to the Test for heavy metals (see Part III, Test No. 3). A solution of Cerium Oxalate (1 in 25) in hot dilute sulphuric acid (1 in 3) meets the requirements of the Test for arsenic (see Part III, Test No. 1). Boil 0.3 Gm. of Cerium Oxalate with 15 mils of potassium hydroxide T.S. and filter. No precipitate is produced in 5 mils of the filtrate by boiling with an excess of ammonium chloride T.S. (*aluminum*) or in another 5 mil portion of the filtrate by the addition of sodium sulphide T.S. (*zinc*)." *U. S.*

As usually seen in commerce it has a pinkish tinge, due to the presence of a trace of a compound of didymium. The British Pharmacopœia, 1898, state that it was "an almost white granular powder, insoluble in *water*, decomposed at a dull red heat, yielding a reddish-brown powder which dissolves completely and without effervescence in boiling *hydrochloric acid;* the resulting solution gives with a saturated solution of *potassium sulphate* a white crystalline precipitate. When incinerated it loses 53 per cent. in weight. It should yield no characteristic reaction with the tests for arsenium, iron, aluminium, zinc, calcium, carbonates, or phosphates."

Uses.—Bachem (*A. I. P. T.*, xvii, p. 363)

has shown that cerium, didymium and lanthanum are all practically non-toxic although some of their salts possess antiseptic virtues. The commercial cerium oxalate being almost insoluble is not absorbed when given by the mouth and escapes wholly through the feces. It was originally brought forward by Sir James Y. Simpson as a remedy for the *vomiting of pregnancy* and has been used extensively in this affection and also in various other gastric disturbances attended with vomiting. Baehr and Wessler (*A. in M.*, 1909) have shown, however, that it has no effect in vomiting which is of central origin. Its value as an antemetic is probably precisely parallel to that of the insoluble salts of bismuth; when used in large quantities it forms a protective coating over the mucous membrane of the stomach.

The soluble cerium nitrate was believed by Simpson to be a nerve tonic and useful in irritable *dyspepsia* and chronic *vomiting* in doses of from one-half to one grain (0.032–0.065 Gm.).

Dose of cerium oxalate, one to ten grains (0.065–0.65 Gm.) three or more times a day.

CETACEUM. U. S., Br.

SPERMACETI Cetac.

(cē-tā′cē-ŭm)

"A concrete, fatty substance, obtained from the head of the sperm whale, *Physeter macrocephalus* Linné (Fam. *Physeteridæ*)." *U. S.* "Spermaceti is a solid wax obtained from the Sperm Whale, Physeter macrocephalus, *Linn.*, and possibly other species." *Br.*

Blanc de Baleine ou Cétine, *Fr. Cod.*; Spermacéti, Cétine, Ambre Blanc, *Fr.*; Cetaceum, *P. G.*; Walrat, Wallrath, Spermaceti, *G.*; Cetina, Spermaceti, *It.*; Esperma de ballena, Sperma ceti, *Sp.*

The spermaceti whale is from sixty to eighty feet long, with an enormous head, not less in its largest part than thirty feet in circumference, and constituting one-third of the whole length of the body. The upper part of the head is occupied by large cavities, separated by cartilaginous partitions, and containing an oily liquid, which, after the death of the animal, concretes into a white spongy mass consisting of spermaceti mixed with oil. This mass is removed, and the oil allowed to separate by draining. The crude spermaceti obtained from a whale of the ordinary size is more than sufficient to fill twelve large barrels. It still contains much oil and other impurities, from which it is freed by expression, washing with hot water, melting, straining, and repeated washing with a weak boiling potash lye. Common whale oil and the oil of other cetaceous animals contain small quantities of spermaceti, which they slowly deposit on standing. According to W. Gilmour, *sperm oil* should contain not less than 4 per cent. of cetin, and if much less be obtained by the following process, adulteration has been practised. Shake one part by weight of sulphuric acid (sp. gr. 1.84) with four parts of the oil; allow to stand 20 minutes, shaking twice; add three parts of distilled water; shake this thoroughly, and allow to stand from 16 to 20 hours; dilute with 3 or 4 times its volume of distilled water; agitate thoroughly. On standing, the cetin floats upon the top, and can readily be skimmed off, washed, dried, and weighed. (*P. J.*, vii, 328. See also *Chem. Ztg.*, 1893, 1453, and *Am. Drug.*, 1895, 105.)

Properties.—Spermaceti is officially described as in "white, somewhat translucent, slightly unctuous masses, with a scaly, crystalline fracture, a pearly luster, a very faint odor and a bland, mild taste. It becomes yellowish in color and rancid on prolonged exposure to air. It is insoluble in water and nearly so in cold alcohol; soluble in boiling alcohol, in ether, chloroform, carbon disulphide, or fixed or volatile oils; only slightly soluble in cold petroleum benzin. Specific gravity: 0.938 to 0.944 at 25° C. (77° F.) as determined by the method given under *Cera Flava*. It melts between 42° and 50° C. (107.6° and 122° F.). It dissolves completely in 50 parts of boiling alcohol (*paraffin*), and the solution is neutral or not more than slightly acid to moistened litmus paper. Warm a mixture of about 1 Gm. of Spermaceti and 10 mils of ammonia water until the Spermaceti is melted, then shake it thoroughly in a stoppered vessel for a few minutes, cool and filter. The filtrate, upon supersaturation with hydrochloric acid, may become turbid, but yields no precipitate (*stearic acid*)." *U. S.*

"Translucent, pearly-white, glistening masses, with a leafy, crystalline structure; slightly unctuous to the touch. Almost inodorous. Specific gravity 0.950 to 0.960; *acid value* not more than 1.0; *saponification value* 125 to 136; *iodine value* 3 to 4.4; *refractive index* at 80° C. (176° F.) about 1.4330. Soluble in 50 parts of hot *alcohol* (90 per cent.), the greater proportion separating again in thin laminæ on cooling. Reducible to powder with the aid of a little *alcohol* (90 per cent.). When 1 gramme is boiled with 10 millilitres of *alcohol* (90 per cent.) for one minute, and the mixture cooled to, and filtered at 0° C. (32° F.) the filtrate when poured into *water* may become opalescent, but does not afford a precipitate (absence of stearic acid)." *Br.*

As found in commerce it is not chemically pure, containing a fixed oil, and often a peculiar coloring principle. From these it is separated by boiling in alcohol, which on cooling deposits it in crystalline scales. Thus purified, it does not melt under 49° C. (120° F.), is soluble in 40 parts of boiling alcohol of the sp. gr. 0.821 (Thénard), and is harder, more shining, and less unctuous than ordinary spermaceti. Spermaceti is a mixture of various fats. When recrystallized from alcohol as just described, the purified *cetin* is obtained, while the alcohol on evaporation deposits an oil (mechanically admixed sperm oil). The cetin which crystallizes out of the alcohol is essentially *cetyl palmitate*, $C_{16}H_{33}(C_{16}H_{31}O_2)$—that is, a compound of *cetyl alcohol* (*ethal* of Chevreul), $C_{16}H_{33}.OH$, and *palmitic acid*, $C_{16}H_{32}O_2$. According to Heintz, however, there

are small amounts of other fats with the cetin; fats containing the acids *stearic*, $C_{18}H_{36}O_2$, *myristic*, $C_{14}H_{28}O_2$, and *lauro-stearic*, $C_{12}H_{24}O_2$, and the alcohol radicals corresponding to these acids.

L. F. Kebler, after examining about twenty samples of spermaceti, found that commercial specimens have a melting point of from 42° to 47° C. (107.6°–116.6° F.), a specific gravity ranging from 0.905 to 0.945 at 15° C. (59° F.) and saponification numbers from 125.8 to 134.6. (*A. J. P.*, 1896, 7, and 1897, 104.)

Uses.—Spermaceti exercises emollient effects like other fatty substances, but it has no other remedial properties. It is used chiefly to add firmness to ointment bases. It may be reduced to powder by the addition of a little alcohol or almond oil, or by melting it at a very low heat, pouring into a warm mortar, and agitating it until perfectly cold; an emulsion may be made by mixing spermaceti first with half its weight of olive oil, then with powdered gum arabic, and lastly with water. Spermaceti Cerate (*Ceratum Cetacei*, U. S. 1890) was made by melting together 10 parts of spermaceti and 35 parts of white wax and then adding 55 parts of warmed olive oil.

Off. Prep.—Unguentum Aquæ Rosæ, *U. S., Br.;* Unguentum Capsici, *Br.;* Unguentum Cetacei, *Br.*

CHIRATA. Br.

CHIRETTA

(chĭ-rā'tą)

"Chiretta is the plant, Swertia Chirata, *Buch.-Ham.*, collected when in flower, and dried." *Br.* "The dried plant of *Swertia Chirayita* (Roxburgh) Hamilton (Fam. *Gentianaceæ*)." *N. F.*

East Indian Balmony; Chiretta; Chirette, *Fr.;* Chiretta Ostindischer Enzian, *G.*

Chirata was for many years official in the U. S. Pharmacopœia and is still retained by the British authority and in the N. F. According to Lloyd, this drug has long been held in esteem by the Hindoos. It first attracted attention in England in 1829 and was introduced into the Edinburgh Pharmacopœia in 1839.

Swertia Chirayita (Roxb.), Hamilton (*Ophelia Chirata*, Griesbach).—The *chirayta*, or *chirata*, is an annual plant, about three feet high, with a branching oblique root, and an erect, smooth, slightly winged branching stem, and furnished with opposite, lanceolate, very acute, entire, smooth, three or five-nerved leaves. The flowers are numerous, peduncled, yellow, with a four-cleft calyx having linear acute divisions, the limb of the corolla spreading and four-parted, four stamens, a single style, and a two-lobed stigma. The capsules are unilocular. The plant is a native of Nepaul and other parts of Northern India. The whole of it is gathered when the flowers are well advanced. In the Indian bazaars the name chirata is applied to various dried gentianaceous plants; the most important of these is the *Ophelia angustifolia* (Buch.-Ham.). It yields the *Paharee* or *Hill chirata*, which is distinguished by its inferior bitterness, and its rectangular, winged stems, whose section presents a thick woody ring and a centre nearly or entirely hollow, with only traces of pith. A false chirata, which also found its way into the London markets, and resembles the official variety in having a well developed pith, but which is completely lacking in bitterness, is affirmed to be the product of *Ophelia alata*. (*P. J.*, xvii, 903.) Under the name of *Indian chirata*, the dried plant of the *Andrographis paniculata* Nees has appeared in the London market. It resembles much more closely recently dried broom tops than the true chirata. It is a little more than two feet long. The branching stems are from ⅛ to ¼ inch in thickness near the base, woody, quadrangular, furrowed, smooth, slightly knotted at the point from which the branches spring, the longitudinal furrows are continued through the roots, which have numerous fine radicles, the leaves are opposite decussate, branches erect or forming an acute angle with the stem, terminal shoots extremely slender.

The dried plant is imported into Europe in bundles, consisting mainly of the stems, with portions of the root attached. The stems contain a yellowish pith. The drug is officially described as "Stem about one metre long, smooth, brown, or purplish-brown, slightly winged and much branched above, rounded below and containing a large, continuous, easily separable pith. Root oblique. Branches slender, elongated, decussate. Leaves opposite, ovate, glabrous, entire, usually with three to seven lateral veins. Flowers small, numerous, panicled. Fruits superior, bicarpellary, unilocular. No odor; taste extremely bitter." *Br.*

It is described in the N. F. as "smooth, root simple, about 7 mm. in thickness near the crown, stem about 1 M. in length, externally yellowish- or purplish-brown; cylindrical near the base, quadrangular and slightly winged above, with numerous opposite, ascending branches; wood yellowish, thin, enclosing usually a large yellowish easily separable pith; leaves opposite, sessile, ovate-lanceolate, entire, five nerved, about 6 cm. in length; flowers numerous, panicled, small, with a four-lobed calyx and corolla, capsule ovoid, acute, one-celled, many-seeded. Odor slight; taste intensely bitter. Chirata yields not more than 6 per cent. of ash." *N. F.*

The virtues of chirata are imparted to water and alcohol, and are retained in the extract. According to Lassaigne and Boissel, the stems contain resin, a yellow bitter substance, brown coloring matter, gum, and various salts. Flückiger and Höhn, who subsequently examined the stems and roots of chirata, extracted from them sugar, wax, chlorophyll, soft resin, tannin, an acid which they name *ophelic*, possessing the formula $C_{13}H_{20}O_{10}$, and a peculiar bitter substance, denominated *chiratin*, $C_{26}H_{48}O_{15}$. The acid is syrupy, deliquescent, yellowish-brown, at first slightly sour, afterwards intensely bitter. It is soluble in water, with some turbidness, probably owing to resin mixed with it, and com-

pletely soluble in alcohol, or a mixture of this with ether. It decomposes certain salts, and forms amorphous compounds with acids. Chiratin is a yellow, hygroscopic powder, but feebly crystallizable, very bitter, sparingly soluble in cold water, more so in hot water, and readily dissolved by alcohol and ether. It is neutral to test paper, and yields a copious precipitate with tannic acid. By the action of acids, chiratin is separated into ophelic acid, and a yellowish-brown, amorphous substance, bitter, scarcely soluble in water, readily soluble in alcohol, and not reducing copper solutions, as the ophelic acid does. Höhn gives it the formula $C_{13}H_{24}O_3$, and names it *chiratogenin*.

Uses.—Chirata has long been used in India. It has been introduced into Europe, and appears to be highly esteemed, but has not been employed to any considerable extent in this country. Its properties are those of the pure bitters, and probably do not differ from those of the other members of the family of *Gentianaceæ*. (See *Gentiana*.) Like these, in overdoses it nauseates and oppresses the stomach. Some have supposed that, in addition to its tonic properties, it exerts a peculiar influence over the liver, promoting the secretion of bile and correcting it when deranged, and restoring healthy evacuations in cases of habitual costiveness. It has been used in *dyspepsia*, and in the *debility* of convalescence, and generally in cases in which corroborant measures are indicated. In India it has been employed in *intermittents* and *remittents*, combined with the seeds of *Guilandina Bonducella* L. It may be given in powder, infusion, tincture, or fluidextract.

Dose, ten to twenty grains (0.65–1.3 Gm.).

Off. Prep.—Infusum Chiratæ, *Br.*; Tinctura Chiratæ, *Br.*; Fluidextractum Chiratæ, *N. F.*

CHLORAL FORMAMIDUM. Br.

CHLORAL FORMAMIDE [Chloralamide]

(ȼhlō'rạl för-mạ-mī'dŭm)

"Chloral Formamide, $C_3H_4Cl_3NO_2$, may be obtained by the direct combination of formamide with anhydrous chloral. Should be preserved in amber-colored bottles." *Br.* "A crystalline solid [$CCl_3.CH(OH)NH.COH$], made by the direct union of formamide with anhydrous chloral. It should be kept in amber-colored, well-stoppered vials. "*U. S.* VIII.

Chloralamide; Chloralum formamidatum, *P. G.*; Chloralformamid, *G.*

Chloralformamide was dropped from the U. S. P. IX. It is made by mixing 45 Gm. of formamide with 147 Gm. of anhydrous chloral, when combination ensues; the crystalline mass is purified by recrystallization.

Properties.—Chloralformamide is officially described in the Br. Pharm. as in "colorless lustrous crystals. No odor; taste slightly bitter. Soluble in 21 parts of *water;* very soluble in *alcohol* (90 per cent.), the solution being neutral to *litmus;* very soluble in *ether;* slowly soluble in 12 parts of *glycerin.* Melting point 114° to 115° C. (237.2°–239° F.); decomposes at a higher temperature. Hydrolyses in aqueous solution at 60° C. (140° F.), yielding chloral hydrate and formamide. Unaffected by dilute acids, but decomposed when warmed with *solution of sodium hydroxide,* chloroform separating and ammonia and sodium formate being produced. Heated with free access of air it volatilises completely without the evolution of inflammable vapors (absence of certain organic impurities). Its solution in *alcohol* (90 per cent.) is not immediately altered in appearance by *solution of silver nitrate* (absence of certain decomposition products)." *Br.*

Chloralimide, $CCl_3.CH{=}NH$, should not be confounded with chloralamide. Chloralimide is in colorless, inodorous, and insipid, long crystalline needles; melting at about 166° C. (330.8° F.); insoluble in water; readily soluble in alcohol, in ether, in chloroform, and in oils. Concerning its physiological action we have no certain knowledge; it is asserted to be hypnotic in doses of from fifteen to sixty grains (1 to 3.9 Gm.).

Uses.—Locally, chloralformamide is scarcely at all irritant, and when taken internally is quickly absorbed and is eliminated chiefly as urochloralic acid. When given to the lower animals, it produces lethargy, sleep, muscular relaxation, arrested respiration, followed by coma, failing respiration, and, if the dose has been sufficient, death by centric respiratory paralysis. As shown by the experiments of H. C. Wood and Cerna, subsequently confirmed by various observers, its influence upon the circulation and the spinal cord is extremely feeble, and it has no perceptible effect upon the nerve trunks and the muscles. As an hypnotic it resembles hydrated chloral, but its action is more slowly developed and is less positive. Confusion, giddiness and headache are the only unpleasant effects following its use, and they rarely occur.

Dose, fifteen to forty-five grains (0.9–3.0 Gm.), half an hour before the desired time of sleep.

CHLORALUM HYDRATUM. U. S. (Br.)

HYDRATED CHLORAL Chloral. Hydrat. [Chloral, U. S. 1890, Chloral Hydrate]

(ȼhlō'rạl-ŭm hȳ-drā'tŭm)

"A compound of trichloraldehyde or chloral, with the elements of one molecule of water. It contains not less than 99.5 per cent. of $C_2HCl_3O + H_2O$ or $CCl_3.COH + H_2O$ (165.4). Preserve it in tightly-stoppered bottles, in a cool place, protected from light." *U. S.* "Chloral Hydrate, $C_2Cl_3H_3O_2$, may be obtained by the addition of water to the liquid chloral, C_2Cl_3HO, produced by the action of dry chlorine gas on ethylic alcohol." *Br.*

Chloral Hydras, *Br.*; Trichloraldehyd Hydrate, Trichlorethylidene Glycol; Hydrous Chloral; Chloral Hydraté *Fr. Cod.*; Hydrate de Chloral, *Fr.*; Chloralum Hydratum, *P. G.*; Chloral hydrat, *G.*; Cloralio idrato, *It.*; Hidrato de cloral, *Sp.*

Perhaps no medicine ever came so rapidly into extensive use as that now under consideration. Though discovered by Liebig in 1832, it was not until 1869 that its remedial properties were first made known by their discoverer, Otto Liebreich of Berlin; in 1878 the consumption of chloral was estimated at one ton daily in England and America alone; and, although not used now to this extent, it is still largely employed.

Anhydrous Chloral.—In preparing anhydrous chloral, the simple method originally employed by Liebig, of acting directly on alcohol by chlorine, is generally preferred, even, we believe, by the larger manufacturers. The following details of the manufacture of hydrated chloral as carried out on a commercial scale have been supplied by E. Schering of Berlin, who has been for years the largest manufacturer of it.

Absolute alcohol, in lots of 50 pounds each, is placed in large glass flasks and saturated with chlorine, which is passed in a continuous stream for 6 to 8 weeks. The chlorine is led into cold alcohol at first, and when no more is is absorbed, the alcohol is heated at first gently and then to 60° C. (140° F.). When saturated, the mixture formed, in which the chloral now exists as chloral alcoholate, is agitated with sulphuric acid at a temperature of 60° C. (140° F.) for several hours, during which time most of the hydrochloric acid escapes. The separated chloral is then rectified over calcium carbonate. The pure chloral so obtained is then mixed in glass flasks with the necessary amount of water, and the resulting hydrated chloral either cast into cakes or purified by crystallization. As solvents for this purpose certain of the side products of the chloral manufacture, after being purified and rectified, are used, for instance, ethylene and ethylidene chlorides; or in their absence chloroform is used; petroleum benzin and carbon disulphide have also been recommended. The action of chlorine upon alcohol is said to be aided by the presence of "chlorine carriers," such as iodine, ferric chloride, thallium chloride, etc. The formula of anhydrous chloral is C_2Cl_3HO; in other words, aldehyde, C_2H_4O, in which 3 atoms of hydrogen have been replaced by 3 atoms of chlorine. The name of chloral was derived from the *chlor*ine and *al*cohol from which it is formed. The anhydrous chloral thus formed is a colorless liquid, of penetrating disagreeable odor, of little taste, of the sp. gr. 1.502, and boiling at 94° C. (201.2° F.). It is soluble in ether or chloroform without change. According to A. Trillat, in the formation of chloral from alcohol, the latter is first changed by the action of the chlorine into aldehyde; this unites with alcohol to form acetal, which is changed successively into mono-, di-, and trichloracetal; the action of hydrochloric acid decomposes this latter with the formation of chloral alcoholate and ethyl chloride; sulphuric acid decomposes the alcoholate, liberating chloral, which then is made to combine with water to form the crystalline hydrated chloral. (*Bulletin*, 1897, 17, 230.) As the union of hydrated chloral with water develops heat, it is supposed to be more than the formation of a hydrate, and the formula $CCl_3.CH{-}OH$ is assigned to the

$$\diagdown OH$$

resulting compound. It does not show all the reactions of an aldehyde, as, for example, the red color of a magenta solution that has been decolorized with sulphurous acid, is not restored by it.

Meta-chloral.—By continued contact of anhydrous chloral and concentrated sulphuric acid, a change is effected in the chloral, by which it becomes a solid insoluble in water, which is designated as *insoluble chloral*, or *meta-chloral*. It is tasteless, of a white color resembling porcelain, and insoluble in alcohol and ether. Its formula is $C_6H_3Cl_9O_3$, being formed by the union of three molecules of chloral. It is stated that when perfectly pure, chloral does not become polymerized; the change is also said to be prevented by the addition of a little chloroform. When heated to 180° C. (356° F.), metal-chloral distils with reversion to liquid chloral. (Allen, *Com. Org. Anal.*, 2d ed., i, p. 171.)

Chloral Alcoholate.—A compound obtained by Roussin, which he announced as pure hydrated chloral, was found by Personne to contain no water, but to be in fact a compound of alcohol and chloral, and is now known by the name of *chloral alcoholate*, C_2HCl_3O,C_2H_6O. It results directly from the action of absolute alcohol on anhydrous chloral, and is now known to be formed as a stage in the manufacture of chloral from alcohol. As it is very likely to be confounded with hydrated chloral, the following points of difference should be noted. It forms white crystals melting at 46° C. (114.8° F.), and boils at 113.5° C. (236.3° F.), while hydrated chloral crystals melt at 58° C. (136.4° F.), and boiling at 97.5° C. (207.5° F.); chloral alcoholate melts without complete solution when warmed with two volumes of water, and, on cooling, congeals below the surface of the water, while hydrated chloral is soluble in one and one-half times its weight of water; chloral alcoholate, gently heated with nitric acid of 1.2 sp. gr., is violently attacked, while hydrated chloral is scarcely acted on; chloral alcoholate, when heated on platinum foil, inflames readily, while hydrated chloral scarcely burns. (Allen, *Com. Org. Anal.*, 2d ed., i, p. 172.)

The three related products, *anhydrous chloral*, polymeric *meta-chloral*, and *alcoholate*, described above, have been more or less introduced into the European markets, and have required some notice to prevent them from being confounded with hydrated chloral, which is alone official. The following observations will be confined to this last compound, and the reader will note that whether the simple term chloral, or the exact designation, hydrated chloral, is used, the same substance is intended.

Properties of Hydrated Chloral.—This is made by simply mixing anhydrous chloral

with water. Acicular crystals soon form, which result from the union of a molecule each of the chloral and water, constituting hydrated chloral. As employed in the United States, this comes from Europe. It was at one time made in this country by E. R. Squibb of Brooklyn. It occurs in commerce mainly in two forms; in distinct crystals, which is the official form, or in crystalline plates, about three lines in thickness, broken into small, irregular pieces, so as to be readily introduced into broad-mouthed bottles. These pieces, while retaining their tabular form, are somewhat translucent, but usually covered with a white powder, which somewhat conceals that property. This is the more common form and the cheaper; but the crystals are to be preferred, as their purity may be relied on. Guerin adds his testimony to the necessity for dispensing only hydrated chloral which has been recrystallized and which is in the form of distinct crystals. He examined many samples, and found acidity in the cake variety, due, as he believes, to the formation of hydrochloric and formic acids, produced by the action of water retained in the cake during the manufacture, and this remaining in contact with the crystals excites decomposition.

Hydrated chloral is white, possessing a peculiar pungent odor, and an acrid pungent taste, especially affecting the velum pendulum. The odor has been compared to that of an overripe melon. Exposed to the air it very slowly volatilizes, and, like camphor, when enclosed in a bottle, covers the interior surface with numerous minute crystals. The boiling point of the pure crystals is 97.5° C. (207.5° F.). If the boiling point be under 95° C. (203° F.), it indicates an under-hydrated preparation; if above 98° C. (208.4° F.), an over-hydrated one. (E. R. Squibb.) The pure hydrated chloral does not take fire when heated in a spoon, but evaporates without residue. With the aid of heat, its solution may be effected readily in chloroform; and the solution, on cooling, deposits it in beautiful crystals, which are generally needle-shaped, while those deposited from a solution in carbon disulphide are prisms. The aqueous solution is prone to decomposition, which is ultimately attended with the development of low organisms. Hydrated chloral should not, therefore, be kept long in this state. (E. Labbée, *A. G. M.*, Sept. 1, 1870.)

In its relation to acids and alkalies it is neutral or, according to E. Schering, slightly acid when perfectly pure. When equal parts of hydrated chloral in crystals and of camphor in small fragments are shaken together in a bottle, and allowed to stand, they liquefy, forming a clear solution. When hydrated chloral and sulphuric acid are mixed, the temperature is greatly reduced. A solution of hydrated chloral dissolves morphine, quinine, and most of the vegetable alkaloids. (R. F. Fairthorne, *A. J. P.*, Oct., 1871, p. 447.) When ammonium sulphide is added to an aqueous solution of hydrated chloral, the mixture rapidly turns yellow, and, after passing through several shades of color, finally becomes dark brown. From this liquid diluted sulphuric acid throws down a bulky brown precipitate. This, purified from precipitated sulphur and dried, is a light-brown powder of the composition $C_{18}H_{24}S_{13}N_4O_6$. Hydrogen sulphide gas forms a sulphydrate by its action on hydrated chloral. These reactions are important, as the detection of metallic poisons in toxicological cases by hydrogen sulphide has been complicated by the presence of hydrated chloral. A still more important chemical reaction of hydrated chloral is that which takes place when the hydrated, or either of its other forms, is placed under the influence of an alkali. Chloroform is developed, and along with it a formate of the alkali employed. Thus, in a strong solution of potassium hydroxide, put a pinch of powdered hydrated chloral, and almost instantly the odor of chloroform becomes sensible, and some oil-like globules of chloroform may be seen at the bottom of the vessel. The reaction is as follows:

$C_2HCl_3O.H_2O$	+	KOH	=
Hydrated chloral		potassium hydroxide	
$CHCl_3$	+ $CHO.OK$	+	H_2O
chloroform	potassium formate		water

This relation of hydrated chloral to chloroform would serve as a ready test of the former, and may be used also to determine its quality, for pure hydrated chloral ought by calculation to yield 76.35 per cent. of chloroform, and the best known yields, according to the table of Mason, 71.5 (72.20 Selden) per cent. If, therefore, the product of chloroform should fall much below the latter percentage, the parcel acted on is probably impure. For other methods of assaying hydrated chloral see Allen, *Com. Org. Anal.*, i, pp. 174 and 175. The following description and tests are given in the U. S. Pharmacopœia: "Hydrated Chloral occurs in rhomboidal, colorless, transparent crystals which do not readily attract moisture. It has an aromatic, penetrating, and slightly acrid odor, and a bitterish, caustic taste. It is slowly volatilized when exposed to the air. One Gm. of Hydrated Chloral dissolves in 0.25 mil of water, 1.3 mils of alcohol, 2 mils of chloroform, and 1.5 mils of ether at 25° C. (77° F.); very soluble in olive oil, freely soluble in oil of turpentine. Hydrated Chloral is decomposed by caustic alkalies, alkaline earths, and ammonia, chloroform and a formate of the base being produced. When warmed with a few drops of aniline and sodium hydroxide T.S., the intensely disagreeable odor of phenylisocyanide is produced. Gently ignite 2 Gm. of Hydrated Chloral; no inflammable vapors are evolved (distinction from *chloral alcoholate and ethyl carbamate*). On complete incineration not more than 0.05 per cent. of ash remains. Ten mils of an alcoholic solution of Hydrated Chloral (1 in 20) does not at once redden moistened blue litmus paper, nor at once become opalescent on the addition of a few drops of silver nitrate

T.S. (*hydrochloric acid and chlorides*). Shake about 0.5 Gm. of Hydrated Chloral, at intervals of five minutes during one hour, with 5 mils of sulphuric acid in a glass-stoppered tube, which has previously been rinsed with sulphuric acid. The acid remains colorless, or very nearly so when viewed transversely in a tube of about 20 mm. diameter (*organic impurities*)." *U. S.*

"In colorless, non-deliquescent, nonoclinic plates. Pungent, but not acrid odor; taste pungent and rather bitter. Soluble in less than 1 part of *water, alcohol* (90 per cent.), or *ether,* and in 3 parts of *chloroform.* Aqueous solution neutral or only slightly acid to *litmus.* Melting point 49° to 53° C. (120.2°–127.4° F.); at a slightly higher temperature it volatilises without residue. Decomposed by alkalies with liberation of chloroform. A solution in *chloroform,* shaken with *sulphuric acid,* imparts no color to the acid (absence of certain organic impurities). When 1 gramme of Chloral Hydrate is warmed with 6 millilitres of *water* and 0.5 millilitre of *solution of sodium hydroxide,* the mixture filtered, sufficient *N/10 solution of iodine* added to impart a deep brown color, and the whole set aside for an hour, no yellow crystalline precipitate is produced (absence of chloral alcoholate). Its aqueous solution yields no precipitate with *solution of silver nitrate* (absence of free chlorides.)" *Br.*

The most delicate test for the presence of chloral alcoholate in hydrated chloral is said to be that with nitric acid. When 1 mil of nitric acid (1.38 sp. gr.) is poured over 1 Gm. of hydrated chloral a yellow color should not appear within 10 minutes, even if the mixture be warmed. (*A. J. P.,* 1894, 191.) For other tests for hydrated chloral by Jaworowski, the reader is referred to *Ph. Z. R.,* 1894, 373.

"**Assay.**—Dissolve about 4 Gm. of Hydrated Chloral, accurately weighed, in 10 mils of distilled water, add 30 mils of normal potassium hydroxide V.S., and allow the mixture to stand two minutes; then add phenolphthalein T.S., and determine the residual alkali at once by titration with normal sulphuric acid V.S. It shows not less than 99.5 per cent. of $C_2HCl_3O+H_2O$. Each mil of normal potassium hydroxide V.S. consumed corresponds to 0.1654 Gm. of $C_2HCl_3O+H_2O$. Each gramme of Hydrated Chloral corresponds to not less than 6.02 mils of normal potassium hydroxide V.S." *U. S.*

Uses.—The physiological action of hydrated chloral may be summed up as follows:—its dominant effect is to depress the centers of consciousness, the soundness of the sleep produced being proportional to the quantity ingested. In somewhat larger doses it is depressant to the motor side of the spinal cord and respiratory center but the sensory apparatus is unaffected except after poisonous doses. In full dose it tends to lower blood pressure probably chiefly through an action upon the vasomotor center, although after large quantities there is a direct depressant influence upon the heart muscle. In poisonous doses it produces profound coma with anesthesia. After fatal quantities death is generally due to stoppage of the respiration through paralysis of the nerve centers, although sometimes due to sudden heart failure. Chloral has little effect on the secretions, although it is stated to somewhat increase the flow of urine. It escapes from the body through the kidneys, probably in part unchanged, although partially in the form of urochloralic acid. This latter body has the property of reducing Fehling's solution. The theory of Liebreich which led to the introduction of this drug into medicine, that it was decomposed by the alkalies of the body with the gradual liberation of chloroform, has been abundantly disproven.

Hydrated chloral is used internally in medicine as a somnifacient, as an antispasmodic, and externally as a local anesthetic, disinfectant and deodorizer. For the relief of *insomnia* not caused by pain it is one of the most certain hypnotics which we possess and is therefore especially employed in the more obstinate forms of sleeplessness such as in *delirium tremens* and certain types of *insanity.* Its action is very prompt, sleep generally beginning within fifteen minutes or half an hour after its oral administration. The effects, however, do not usually last over three or four hours. When the wakefulness is caused by pain it is greatly inferior to the opiates but even here is often of service as an adjuvant. In cases of circulatory weakness it should be used always with great caution if at all, on account of its liability to depress the heart. As a somnifacient it is rarely necessary to give more than 15 grains at a dose.

It is also a remedy of great value in the treatment of various *convulsive disorders.* The determination whether or not to administer chloral in an individual case should be based upon the severity, rather than the type, of the convulsions, thus in *tetanus* and *strychnine poisoning* in which death may be the direct result of the spasm, it is one of the most frequently employed of remedies and justly so. On the other hand, in *epilepsy* ordinarily the convulsions are of no importance and, as the chloral does not lessen the convulsive tendency, it is not often of service; but in the condition known as *status epilepticus* it may prove of great value. It is also occasionally demanded in severe cases of *hysteria* and *chorea.* Certain local spasms, such as *laryngismus stridulus, asthma,* and *hiccough,* are at times greatly benefited by its employment.

Locally it is used to a larger extent in combination with camphor or methyl salicylate as an anodyne and counter-irritant. Occasionally it is employed as a stimulating antiseptic to *wounds,* although its antibacterial powers are comparatively feeble. It has, however, been highly recommended by Siegmund (*Th. M.,* 1909) as a deodorizant in *gangrene of the lung* and various other malodorous conditions. It is said also that it is valuable for washing the hands after post-mortem examinations, acting both as a disinfectant and deodorizer. A two per cent. solution has been recommended by Quincke as a spray in *tonsilitis* and other in-

flamed conditions of the oral or nasal cavities.

Occasionally hydrated chloral in even not excessively large doses may produce very unpleasant symptoms, such as various skin lesions or circulatory failure. The latter may be very alarming and at least one case is recorded in which a single dose of thirty grains caused death. The common symptoms of chloral poisoning are: Deep sleep, passing into coma, the pupil at first contracted, later dilates; the respirations fall in number; the pulse is weakened and rendered slower, but later may become rapid and irregular; the temperature is reduced; the muscular system is relaxed, and both sensibility and reflex action are diminished or completely abolished. The immediate cause of death is generally a paralytic arrest of respiration but in many cases there appears to have been a simultaneous arrest of the cardiac action, and it is very possible that fatal syncope may at times occur. At post-mortem examination, congestion of the meninges and substance of the brain and cord, and of the lungs, is commonly found. The blood is thought by Richardson (*M. T. G.*, Sept. 4, 1870) to coagulate less firmly than normal.

In the treatment, if the case be seen early, the stomach should be thoroughly evacuated by a rapidly acting emetic, as zinc sulphate, or the stomach tube, and atropine, strychnine, cocaine, and caffeine, employed as respiratory and circulatory stimulants; at the same time external heat should be applied to maintain the bodily temperature and efforts made to keep the patient awake. For the latter purposes, however, those measures which throw an added strain upon the heart, such as walking, must be sedulously avoided; the electric brush affords the most efficient and least injurious method of preventing sleep.

Hydrated chloral is best administered in solution with syrup of orange flowers, or some simple aromatic. The French sometimes employ *chloral cream,* made of hydrated chloral 5 parts, water 15 parts, white sugar finely powdered 100 parts, flavored with mint, orange, or vanilla. One grain of hydrated chloral is contained in 24 grains of the cream, and a teaspoonful is equivalent to about 3 grains of hydrated chloral. This preparation keeps well, and the dose may be dissolved in a little water. *Chloral liniment* may be made by dissolving 6 parts of hydrated chloral in 30 parts of oil of sweet almonds. *Chloral ointment,* 6 parts hydrated chloral, 3 parts white wax, 27 parts lard; the lard and wax are melted at a gentle heat, the hydrated chloral added in powder and dissolved. *Chloral plaster,* to produce counter-irritant effects, is prepared by spreading powdered hydrated chloral on Burgundy pitch plaster; care should be taken to distribute it uniformly.

Dose, ten to thirty grains (0.65–2.0 Gm.).

CHLOROFORMUM. U.S., Br.

CHLOROFORM Chlorof.

(ĕhlō-rō-fôr′mŭm)

"A liquid consisting of not less than 99 per cent. nor more than 99.4 per cent., by weight, of $CHCl_3$ (119.39), and not less than 0.6 per cent. nor more than 1 per cent. of alcohol. Preserve it in well-stoppered bottles, in a cool place, protected from light. Caution: Care should be used in vaporizing Chloroform in the presence of a naked flame, as noxious gases are produced." *U. S.* "Chloroform is trichlormethane, $CHCl_3$, to which 2 per cent. of Absolute Alcohol has been added. It may be obtained from ethylic alcohol, industrial methylated spirit, or acetone, by heating with chlorinated lime, slaked lime, and distilled water, and subsequent purification. Should be kept cool and in a dark place." *Br.*

Trichlormethane, Methenyl Trichloride; Chloroformum Purificatum, *U. S.* 1880; Formylum Trichloratum; Chloroforme Officinal, *Fr. Cod.;* Chloroformium, *P. G.;* Reines Chloroform, Chloroform, *G.;* Cloroformio, *It.;* Chlorido ormico, Cloroformo, *Sp.*

Neither the U. S. nor British Pharmacopœias give detailed processes for chloroform or for its purification. (See U. S .D., 17th ed., 370, and 19th ed., p. 327.)

It sometimes happens that the chloroform purified with sulphuric acid, though apparently pure at first, will not keep, but after some time becomes so loaded with chlorine and hydrochloric acid as to be altogether unfit for respiration. Squibb attributed the fact that chloroform purified by concentrated sulphuric acid does not keep well, to the very purity attained. He believed that perfectly pure chloroform is prone to decomposition, and is rendered more stable by the addition of a small proportion of alcohol, so as to reduce its density to the official standard. This he effected by adding alcohol in the proportion of ten drops to each fluidounce of good chloroform of maximum density (see *Amer. Med. Monthly,* July, 1857). This recommendation was carried into effect in the U. S. 1880 process, and explains the addition of alcohol before distillation. Gregory also attributes the tendency to decomposition to its purity, and to the action of sunlight; having found that those portions which he had purified with the greatest care were soonest decomposed under the influence of light. For methods of preserving chloroform by the use of sulphur, hypophosphorous acid, etc., see *P. J.,* 1895, 261; also 1896, 249.

The intermediate formation of hydrated chloral as a result of the reaction between alcohol and chlorinated lime suggested the preparation of chloroform from hydrated chloral. The advantages which were anticipated from decomposing pure hydrated chloral with alkalies have not altogether been realized, for the product is much more expensive, and the claim of greater stability has not been sustained, as it requires just as much alcohol to preserve it as that made in the usual way.

Chloroform is now made on a large scale by the distillation of acetone with chlorinated lime; indeed, this process has entirely replaced the manufacture from alcohol. Liebig, as long ago as 1832, described the reaction, but it was thought to be not adapted for commercial use. In 1882 the manufacture was begun on a commercial scale at Mannheim, Germany, and since June, 1885, in this country. To get a satisfactory yield a very pure acetone is necessary. When such acetone is taken, a yield of nearly or quite 200 per cent. of chloroform can be obtained. (For an account of the methods of purifying the acetone and distilling with chlorinated lime, see *A. J. P.*, 1889, p. 321.) In July, 1885, a patent was taken out by G. Michaelis of Albany, for the manufacture of chloroform from the liquid products resulting from the decomposition of crude acetates at high temperatures. These liquid products are acetone and other higher ketones. The purified chloroform from acetone has a small quantity of alcohol added to prevent decomposition and bring it to pharmacopœial requirements. Pure methyl alcohol, on the other hand, does not yield chloroform. The erroneous statements on this point generally current are probably due to the fact that commercial wood spirit contains a large percentage of acetone.

E. R. Squibb preferred acetic acid to the acetates in the intermediate step of making acetone, thus avoiding impurities likely to be present in acetates; he believed that the grant of a patent for "acetone chloroform" was deficient in equity. (*Ephem.*, 1896, 1743 to 1757.)

Still another method for the manufacture of chloroform from acetone is described in the French technical journals,—viz., to electrolyze a solution of common salt mixed with acetone. A retort of enamel-lined iron, jacketed at the bottom so as to be heated by steam, and provided with a delivery and condensing tube, is used. A 20 per cent. solution of common salt is introduced into the retort and heated to boiling, when the current is made to pass and a continuous stream of acetone is run in. The nascent chlorine liberated rapidly converts the acetone into chloroform, and it distils over. It is claimed that 190 per cent. of the weight of the acetone taken is obtained as chloroform. Lead electrodes were used at first, but these have been replaced by carbon rods which can be attached to a vertical shaft and made to serve as stirrers. The negative electrode consists of a copper cylinder. (*Revue Scientifique*, Feb., 1893.)

Carbon tetrachloride (CCl_4) has also been proposed (1896) as a source of chloroform, and as it is now made cheaply on a large scale, it may come into use. By the action of hydrochloric acid and zinc, hydrogen is liberated and attacks the carbon tetrachloride, forming chloroform and hydrochloric acid,

$$CCl_4 + H_2 = CHCl_3 + HCl$$

As hydrochloric acid is a product of the reaction, fresh quantities of zinc are attacked, and a new liberation of chloroform follows.

Discovery and History.—Chloroform was discovered by Samuel Guthrie of Sackett's Harbor, N. Y., in 1831, and about the same time by Soubeiran in France, and Liebig in Germany. Guthrie obtained it by distilling a gallon from a mixture of three pounds of chlorinated lime and two gallons of alcohol of the sp. gr. 0.844, and rectifying the product by redistillation, first from a great excess of chlorinated lime, and afterwards from potassium carbonate. (*Silliman's Journal*, vol. xxi, Jan., 1832, p. 64.) In a subsequent letter to Silliman, dated Feb. 15, 1832, Guthrie states that the substance which he had obtained, "distilled of sulphuric acid, has the specific gravity of 1.486, or a little greater, and may then be regarded as free from alcohol; and if a little sulphuric acid which sometimes contaminates it be removed by washing it with a strong solution of potassium carbonate, it may then be regarded as *absolutely pure.*" (*Ibid.*, vol. xxii, July, 1832, p. 105.) It is thus evident that Guthrie obtained, in a pure state, the substance now called chloroform; but he erroneously supposed his product to be the well known oily liquid of the Dutch chemists, which it greatly resembles, and for the preparation of which he believed he had fallen on a cheap and easy process. Under this impression he called the substance, in his communications, *chloric ether*, one of the names by which *Dutch Liquid*, or *ethene dichloride*, is designated. He was induced to make the preparation from noticing in Silliman's *Elements of Chemistry* a reference to the Dutch liquid as a grateful diffusible stimulant when properly diluted with alcohol and water. (See also *West. Drug.*, 1894, 51.)

Properties.—Chloroform is "a clear, colorless, mobile liquid, of a characteristic, ethereal odor, and a burning, sweet taste. Chloroform dissolves in 210 times its volume of water; miscible with alcohol, ether, benzene, petroleum benzin, or with fixed or volatile oils. Specific gravity: 1.474 to 1.478 at 25° C. (77° F.). Chloroform is volatile at a low temperature and boils at about 61° C. (141.8° F.). It is not inflammable, but its heated vapor burns with a green flame. Pour 20 mils of Chloroform upon a piece of clean, odorless filter paper laid flat upon a warmed glass plate, and rock the plate from side to side until the liquid is all evaporated. No foreign odor becomes perceptible as the last portions disappear from the paper, and the paper remains odorless. Agitate 10 mils of Chloroform with 25 mils of distilled water, and allow the liquids to separate completely; the aqueous layer is neutral to litmus and separate portions of 10 mils each are not affected by a few drops of silver nitrate T.S. (*chlorides*) nor colored blue by the addition of a few drops each of potassium iodide T.S. and starch T.S. (*free chlorine*). Transfer 40 mils of Chloroform from the container, by means of a clean pipette, to a 50 mil glass-stoppered cylinder of colorless glass having an internal diameter of about 20 mm. and previously rinsed with sulphuric acid, add 4 mils of colorless sulphuric acid and shake the mixture vigorously during five minutes.

Then allow the liquids to separate completely, so that both are transparent. The Chloroform remains colorless, and the acid is colorless or very nearly so when viewed horizontally in the cylinder held in a vertical position (*impurities decomposable by sulphuric acid*). Dilute 2 mils of the sulphuric acid, separated from the Chloroform in the preceding test, with 5 mils of distilled water; the liquid is colorless and clear, and, while hot from the mixing, emits but a faint, vinous or ethereal odor (*odorous decomposition products*). When further diluted with 10 mils of distilled water, it remains clear and is not affected within one minute by the addition of 3 drops of silver nitrate T.S. (*chlorinated decomposition compounds*)." *U. S.*

"A colorless, volatile liquid. Characteristic odor; taste pungent, sweet. Specific gravity 1.483 to 1.487. Does not begin to boil below 60° C. (140° F.). On allowing 10 millilitres to evaporate from a large piece of filter paper placed on a warm plate, no extraneous odor is perceptible at any stage of the evaporation. *Water* which has been shaken for five minutes with half its volume of Chloroform, and separated from the undissolved Chloroform, is neutral to *litmus* (absence of acid), does not give any color with 1 millilitre of *solution of cadmium iodide* and 2 drops of *mucilage of starch* (absence of free chlorine), and yields not more than a very slight opalescence with 4 drops of *solution of silver nitrate* (absence of chlorides). After shaking *sulphuric acid* with twice its volume of Chloroform for five minutes, and setting aside for fifteen minutes, both the acid and the Chloroform are nearly colorless. 2 millilitres taken from the layer of *sulphuric acid*, and diluted with 5 millilitres of *water*, remain very nearly colorless, and have a pleasant odor. When this acid liquid is further diluted with 10 millilitres of *water*, and stirred with a glass rod, it is transparent and colorless, and the addition of 4 drops of *solution of silver nitrate* causes not more than a slightly diminished transparency. *Water* which has been shaken with half its volume of Chloroform, previously treated with *sulphuric acid* as described above, yields not more than a slightly diminished transparency with *solution of silver nitrate*. Evaporates without residue." *Br.*

Besnou gives the densities of various mixtures of alcohol and the purest commercial chloroform at 4.5° C. (40° F.) as follows:

Specific Gravity.	Chloroform, per cent.	Alcohol, per cent.	Specific Gravity.	Chloroform, per cent.	Alcohol, per cent.
1.4945	100.0	0.0	1.4772	97.5	2.5
1.4908	99.5	0.5	1.4602	95.0	5.0
1.4874	99.0	1.0	1.4262	90.0	10.0
1.4840	98.5	1.5	1.4090	87.5	12.5

When pure, it has no action on potassium, except to cover the surface of the metal with small bubbles of gas. Chloroform is a powerful antiseptic. Like creosote, it does not coagulate albumin. It is scarcely acted on by sulphuric acid in the cold, but dissolves readily in alcohol and ether.

The alcoholic solution, when moderately diluted with water, forms a sweetish, aromatic liquid of a very grateful taste. A strong alcoholic solution is decomposed by an abundance of water, the chloroform separating and subsiding, and the alcohol uniting with the water.

It is liable to decomposition by sunlight, or even diffused daylight; and hence the propriety of keeping it in bottles covered with dark paper, in a rather dark place. Chloroform has extensive solvent powers, being capable of dissolving caoutchouc, gutta-percha, mastic, elemi, tolu, benzoin, and copal. Amber, sandarac, lac, and wax are only partially soluble. It also dissolves iodine, bromine, many alkaloids, the fixed and volatile oils, most resins, and fats. It dissolves sulphur and phosphorus sparingly.

It possesses the power of dissolving a large quantity of camphor. As a general solvent, it has the advantage over ether of not being inflammable, the inflammability of the latter being the cause of frequent accidents. For an extensive list of substances soluble, insoluble, and partly soluble in chloroform, see a paper by Lepage of Gisors, France, copied into *A. J. P.*, 1852, p. 147. It has been found by J. B. Barnes that chloroform has the power of preventing the alcoholic, lactic, and other fermentations, probably by killing the organisms that provoke these processes. Twenty minims preserved sixteen ounces of malt, to which two drachms of yeast had been added, as long as the experiment lasted. The same quantity kept fresh eight fluidounces of milk in a warm place for five days. Mucilage and infusions were preserved for weeks with one minim or even less to the ounce. Similar results were reached by F. J. Barrett and others. (*P. J.*, 1874, pp. 441, 442, 455.) The active properties of chloroform forbid its use as a preservative of medicinal infusions, but from milk it could always be removed by boiling. A. Munz (*P. J.*, 1875, p. 967) proposes the employment of chloroform as a test between chemical and living ferments, since he has found it to have no effect upon the former, though absolutely destructive to the latter.

Composition.—Chloroform is composed of one atom of carbon, one of hydrogen, and three of chlorine. Its simplest derivation in theory is from marsh-gas (*methane*), CH_4, whence it is often called *trichloro-methane*. While it can be thus produced, by the action of chlorine upon marsh-gas, in practice, it is formed either from alcohol by the action of bleaching powder, from

chloral by an alkaline hydroxide, or latterly from acetone and bleaching powder.

Tests.—Chloroform is liable to contain alcohol and ether, both of which lower its specific gravity. If it have a less density than 1.38, it will float instead of sinking in a mixture of equal weights of concentrated sulphuric acid and water after it has cooled. M. Mialhe has proposed the following tests for the presence of alcohol. Drop into distilled water a small quantity of the chloroform. If pure, it will remain transparent at the bottom of the glass; but if it contain even a small proportion of alcohol, the globules will acquire a milky appearance. Soubeiran's method was to agitate almond oil and chloroform together in a tube. If the chloroform is pure, it remains clear; if it contains as much as 5 or 6 per cent. of alcohol, it becomes milky. (*J. P. C.*, Août, 1860, p. 95.) Procter detected alcohol by adding the suspected chloroform to an oxidizing mixture of potassium dichromate and sulphuric acid. If alcohol be present, the deep orange color of the chromic mixture will gradually become green; if absent, no change of color will take place. (*A. J. P.*, 1856, p. 213.) Hoffmann's violet has been suggested as a test. If a small portion is added to chloroform containing alcohol, the solution is colored a deep purple. Boettger recommends adding to the chloroform a solution of molybdic acid in pure, strong sulphuric acid, when even a trace of alcohol will cause an intense blue color. (1879.) Chloroform, when pure, upon being mixed with an equal volume of sulphuric acid, does not color it; but when contaminated with pyrogenous oils it gives the acid a color varying from yellow to reddish-brown, according to the amount of impurity. Alcohol also is detected and removed by sulphuric acid. In applying this test, several fluidounces of chloroform should be used, as a slight change of color cannot be easily seen in a test tube, and care must be taken to see that mechanical impurities, like cork dust, dirt, etc., have been filtered out of the specimen, or the acid will be discolored from this cause. A still more delicate test of the oily impurities, according to Gregory, is the odor which they leave. If chloroform thus contaminated be poured upon the hand, it quickly evaporates, leaving the oily impurities, recognizable by their offensive odor, now no longer covered by that of the chloroform. The pure substance, rubbed on the skin, quickly evaporates, and leaves scarcely any odor. Chloroform sometimes contains Dutch liquid, which may be discovered by adding an alcoholic solution of potassium hydroxide, when the mixture, if this impurity be present, will heat and give off a permanent gas, which is *acetyl chloride*, C_2H_3OCl. (Geuther.) Fuming nitric acid, heated with chloroform to 100° C. (212° F.) in a closed tube for 120 hours, forms a new substance, *chloropicrine*.

These tests imply the presence of but a minute proportion of alcohol, and the total absence of chlorine and those volatile and empyreumatic substances which constitute the most injurious impurities of chloroform. A heat that would be felt through the bottle, on the admixture of sulphuric acid with chloroform would evince the presence of too much alcohol or water. The want of discoloration from the contact of the two liquids shows the absence of empyreumatic oily matter. A color bordering on that of sherry wine would imply an objectionable amount of impurities. The volatile impurities are less volatile than chloroform, and would consequently be the last to escape on the evaporation of the liquid. Impure chloroform, therefore, leaves a foreign odor behind it when allowed to evaporate from a clean porcelain plate, in the amount and manner indicated.

Two methods for purifying chloroform, one physical and the other chemical, have attracted much attention. The first of these is the Pictet method of purifying the chloroform by submitting it to very low temperatures, whereby the impurities are first frozen out and filtered off from the chloroform at −70° C. (−94° F.) and then the chloroform itself is solidified at from −80° to −100° C. (−112° to −148° F.) and separated from any liquid impurities. It was at first claimed for this "Chloroform Pictet" that it would not be decomposed by sunlight and did not require the addition of alcohol to preserve it. These claims do not seem to be substantiated by later tests. The other method is based on the discovery of R. Anschütz, that chloroform crystallizes out with salicylid, $C_6H_4\left\{\begin{matrix}CO\\O\end{matrix}\right>$, and *o*-homosalicylid, $C_6H_3(CH_3)\left\{\begin{matrix}CO\\O\end{matrix}\right>$, while the impurities of chloroform remain. These crystalline compounds contain respectively 33.24 and 30.80 per cent. of chloroform, and this can be liberated from its combination by very moderate heating. The compounds can be kept for a long time in closed vessels in a slight atmosphere of chloroform, and the salicylid and *o*-homosalicylid can be used over and over again. After becoming acid, through exposure to light, chloroform may be readily regenerated, by agitating it with solution of sodium carbonate, and distilling from a little unslaked lime. From what has been said above, chloroform to be kept for use should have the sp. gr. 1.476, and if denser than this, should be brought to it by the addition of alcohol. It is best kept in cork stoppered bottles. As the cork is not acted on by chloroform, if it become yellow and softened it will indicate the presence of an acid, and thus act as a test. (*A. J. P.*, 1868, p. 289.)

Uses.—Locally chloroform is actively irritant and somewhat anesthetic. When applied to the skin in ordinary manner it produces pain and redness but if evaporation be prevented will frequently blister. The pain is followed by a sensation of numbness. According to Fornié

the vapor from a mixture of equal parts of glacial acetic acid and chloroform is more effectual as a local anesthetic and will produce complete insensibility of the skin in five minutes. (*P. J.*, 1862, p. 385.) Chloroform is also distinctly antiseptic.

Taken into the stomach in doses of about five minims (0.3 mil), it induces only gastric symptoms, chiefly due to its irritant properties; but when there is excessive flatulence, colic, or gastralgia, it not only causes an increased peristalsis and expulsion of any flatus present, but evinces a distinct local narcotic influence by quieting pain and spasm. Taken in doses of 1 to 2 fluidrachms (3.75–7.5 mils), it produces a narcotism similar to that seen when it is administered by inhalation, the narcotism, however, developing and passing off much more slowly than in the latter case. Chloroform was used internally in *asthma* and other conditions as early as 1832 by Ives of New Haven (*Silliman's Journ.*, xxi, 406, 407), and subsequently in various conditions by several European physicians, but it was not until November, 1847, that Simpson of Edinburg brought it forward as more agreeable, efficacious, and convenient in general anesthesia than ether.

The action of chloroform upon the system like that of ether, is predominantly upon the central nervous system. The first portion to feel the effect of the drug is the higher cerebral centers. After larger quantities there is depression of the spinal cord, first of the sensory side and later of the motor tract, and finally paralysis of the medullary centers, especially the respiratory and vasomotor. It differs from ether not only in the power of its action but especially in the fact that it is directly depressant to the heart. A discussion of the relative advantages and disadvantages of these two great anesthetics would occupy too much space to be permissible here and the reader is referred for details to H. C. Wood, Jr.'s *Text-book of Pharmacology*. It may, however, be remarked that under ordinary circumstances chloroform, although more pleasant to take than ether, is much more dangerous. It should also be remembered that it can be absorbed readily through the mucous membrane of the alimentary canal, and in doses of one or two fluidrachms it will produce a narcosis very similar to that which is caused by its inhalation.

Aside from its use in surgery chloroform is sometimes used to relieve severe *pain*, as in *neuralgia, gallstone colic*, and the like. It is also capable of relieving the asthmatic paroxysm. For these properties it is generally administered by inhalation but should only be employed with the greatest caution. Internally it is used as a carminative in *flatulent colic* and as a stimulant in combination with other drugs in the treatment of *serous diarrheas*. It has also been recommended as an anthelmintic, especially in the treatment of *hookworm*, but appears to be more dangerous than other equally efficient drugs. Externally it is very widely employed as a counter-irritant, especially in the form of the liniment. Langenbeck, of Berlin, prefers chloroform to tincture of iodine as an injection for the radical cure of *hydrocele*.

Chloroform ointment is made by adding twenty parts of chloroform to a mixture of ten parts of white wax and ninety parts of lard, previously melted together, and allowing the whole to cool. Chloroform may be gelatinized by agitating it with an equal weight of white of egg in the cold. In three hours it takes the gelatinous form. A stronger preparation may be made by shaking together, in a bottle, four parts of chloroform and one of white of egg, and placing the mixture in water at 60° C. (140° F.). In four minutes the gelatinization is completed. *Gelatinized chloroform* may be applied to the skin, spread on linen, or by friction. *Syrup of chloroform* may be made by adding one fluidounce of spirit of chloroform to fifteen fluidounces of syrup.

When an overdose of chloroform is taken by the mouth, it is essential to empty the stomach by the pump or siphon tube, and then treat the case much as in serious narcosis from inhalation. In a case of suicide by swallowing chloroform in which death took place in about thirty-four hours, the lining membrane of the larynx and trachea was found inflamed, the bronchi were loaded with a dirty-gray purulent fluid, the lungs were inflamed as in the first stage of pneumonia, and the brain and its membranes congested; but these morbid appearances are not constant.

In relation to the preparations, consisting of chloroform and alcohol, which have been used under the name of "chloric ether," the reader is referred to *Spiritus Chloroformi*.

Dose, of chloroform, five to fifteen minims (0.3–0.9 mil).

CHONDRUS. U. S.

CHONDRUS [Irish Moss]

(ĉhŏn'drus)

"The dried plant of *Chondrus crispus* (Linné) Stackhouse or of *Gigartina mamillosa* (Goodenough et Woodward) J. Agardh (Fam. *Gigartinaceæ*)." *U. S.*

Carrageen, Caragahen, Fucus Crispus, Pigwrack, Killeen, Pearl Moss; Carragheen; Carragaheen; Carrageen ou Mousse perlée, *Fr. Cod.;* Mousse Marine perlée, *Fr.;* Carrageen, *P. G.;* Irländisches Moos, Perlmoos, Knorpeltang, *G.;* Fuco carageo, Musco d'Irlanda, Fuco crispo, *It.;* Caragaen, Musgo marino perlado, *Sp.*

Chondrus crispus grows upon rocks and stones on the coast of Europe, and is especially abun-

dant on the southern and western coasts of Ireland, where it is collected. It is also a native of the United States, and is gathered largely on the coast of Massachusetts, below Boston, where it is partly torn from the rocks and partly collected upon the beach, on which it is thrown up during storms. It is prepared for market by spreading it out high on the beach, to dry and bleach in the sun. (Aug. P. Melzar, *Proc. A. Ph. A.*, 1860.) For elaborate accounts of the plant, of its distribution on the sea coast of Massachusetts, and of the mode of gathering and curing, see *U. S. Agricultural Report*, 1866; also *A. J. P.*, 1868, 417; 1895, 596; 1899, 483. Henry Kraemer witnessed the methods pursued on the Massachusetts coast in the collection of Irish moss at Scituate, which appears to be a particularly favorable situation. The season for collection begins late in May and continues to September, June and July being the best months. The moss at present is only found on rocks that are from 15 to 20 feet below the tide, hence women no longer engage in its collection. The men go out in their sail boats or dories at half tide, and come in at half flood. With their long rakes they scrape the moss off the rocks, collecting thus about 50 pounds to the boat, the total for the season at Scituate being about 10,000 pounds. The moss is spread out on the high beach for a week or so, the action of the sun and dew bleaching it. It is then enclosed in hogsheads, in which it is again saturated with sea water by rolling them in the marshes; after which it is again spread out and subjected to the bleaching process, this alternate treatment being repeated four or five times, until the product is of a yellowish or white color. The final drying is done in barns, where the moss is stored until it is packed in 100 lb. barrels at the end of the season. In the course of his journey he had opportunity to observe the *Chondrus* growing and gathered in different localities along the coast, and found it to consist chiefly, if not entirely, of *Chondrus crispus*. While it is stated in Dr. Farlow's "The Marine Algæ of New England" that the closely resembling *Gigartina mamillosa* is common from Boston northward, Kraemer is inclined to believe that *Chondrus crispus* (L.), Lyngbye, is practically the only source of the American drug. (See *Proc. Penn. Pharm. Assoc.*, 1899, 113–116.) Tunmann (*Apoth. Zeit.*, 1909, pp. 91 and 151) has given an elaborate account of the morphology and composition of *Chondrus*.

Gigartina mamillosa Ag. resembles the true Irish moss, and, growing with it upon the rocks, is often gathered with it. It can, however, be at once distinguished by the numerous papillæ which cover the surface and margins of the fronds and bear the fruit (cystocarps). In chemical and medicinal properties it is probably identical with *C. crispus*.

Irish moss when collected is washed and dried. It is probably sometimes bleached by the use of potassium permanganate and sodium thiosulphate by the same process as that used for bleaching sponge. Herr Schack was led to suspect this through discovering the presence of sulphurous acid in a German specimen. (*Ph. Ztg.*, 1886, p. 87.) The presence of arsenic has been determined in some commercial lots, being caused, no doubt, by the impurities in the sulphur used for bleaching Chondrus. Some "faked" samples have yielded as much as 35 per cent. of ash which contained a large quantity of calcium sulphate. The gelatinizing value of specimens of this kind is about 60 per cent. below normal. In the fresh state it is of a purplish color, but, as found in the shops, is yellowish or yellowish-white, with occasionally purplish portions. It is officially described as: "Entire plants more or less matted together, consisting of a slender stalk from which arises a series of dichotomously branching, more or less flattened segments, emarginate or deeply cleft at the tips; from 5 to 15 cm. in length, and 1 to 10 mm. in width; yellowish-white, translucent, frequently coated with a calcareous deposit which effervesces with hydrochloric acid; sometimes with fruit bodies or sporangia embedded near the apex of the segments (in *C. crispus*) or with sporangia borne on short tuberculated projections or stalks, more or less scattered over the upper portion of the segments (in *G. mamillosa*); somewhat cartilaginous; odor slight, seaweed like; taste mucilaginous, saline. Boil one part of Chondrus for about ten minutes with 30 parts of water, replacing the water lost by evaporation; the strained liquid forms a thick jelly upon cooling. When softened in cold water Chondrus becomes gelatinous and transparent, the thallus remaining nearly smooth and uniform and not swollen except slightly at the tips; a solution made by boiling 0.3 Gm. of the drug in 100 mils of water and filtering gives no precipitate on the addition of tannic acid T.S. (*gelatin*), and when cold does not give a blue color on the addition of iodine T.S. (*starch*)." *U. S.*

It swells in cold water, but does not dissolve. Boiling water dissolves a large proportion of it, and the solution, if sufficiently concentrated, gelatinizes on cooling. Herberger found 79.1 per cent. of a so-called pectin (mucilage), and 9.5 of mucus, with fatty matter, free acids, chlorides, etc., but neither iodine nor bromine. Dupasquier discovered in it both of these elements, which had generally escaped attention in consequence of their reaction, as soon as liberated, upon the sodium sulphide resulting from the decomposition of the sodium sulphate of the moss when charred. (*J. P. C.*, 3e sér., iii, 113.) The analysis made by Church in 1877 gave: mucilage, 55.4; water, 18.8; mineral matter, 14.2; albuminoids, 9.4; and cellulose, 2.2 per cent. The pectin Pereira thought peculiar, and proposed to call it *carrageenin*.

It is distinguished from gum by affording, when dissolved in water, no precipitate with alcohol; from starch, by not becoming blue with tincture of iodine; from pectin, by yielding

no precipitate with lead acetate and from mucic acid by the action of nitric acid. Ch. Blondeau gives the name of *goëmine* to a substance obtained by boiling carrageen (*goëmon*, Fr.) for several hours in distilled water, and precipitating the mucilaginous liquid by alcohol. Flückiger, who analyzed this mucilage with care, found in it *no* sulphur, and only 0.88 per cent. of nitrogen. The drug itself yielded not more than 1.012 per cent. of nitrogen. (*Pharmacographia*, 2d ed., 748.) Haedicke, Bauer, and Tollens obtained, on extraction with water containing 0.6 per cent. of sulphuric acid, and further purification by alcohol, a small quantity of a crystalline compound which resembles galactose in its composition, in its action on polarized light, and in its behavior with nitric acid. On oxidation with nitric acid, the dry moss yields from 21.6 to 22.2 per cent. of mucic acid. Carrageenin is said to have been used as a substitute for acacia, under the name of *imitation gum arabic;* the latter occurs in three forms, white, light yellow, and yellow. They all have similar properties, swelling up like tragacanth when mixed with cold water, but not forming a clear solution unless the mixture be boiled, in this latter respect differing from tragacanth or albumen; iodine does not give a blue color, and alcohol does not precipitate the solution, even when 50 per cent. of it is added. It has mild adhesive properties. (E. C. Federer, *Ph. Era*, 1887, 146.) The mucilage of Irish moss has come into considerable use as an emulsifying agent. (*Proc. A. Ph. A.*, 1887; *A. J. P.*, 1888, 170.)

Uses.—Chondrus is nutritive and demulcent, and, being easy of digestion and not unpleasant to the taste, forms a useful article of diet in cases in which the farinaceous preparations, such as tapioca, sago, barley, etc., are usually employed. It has been particularly recommended in *chronic pectoral affections, scrofulous complaints, dysentery, diarrhea,* and *disorders of the kidneys and bladder.* It may be used in the form of decoction, made by boiling a pint and a half of water with half an ounce of the moss down to a pint. Sugar and lemon juice may usually be added to improve the flavor. Milk may be substituted for water when a more nutritious preparation is required. It is recommended to macerate the moss for about ten minutes in cold water before submitting it to decoction. Any unpleasant flavor that it may have acquired from the contact with foreign substances is thus removed.

Dose, four drachms (15.5 Gm.).

Off. Prep.—Gelatinum Chondri, *N. F.;* Mucilago Chondri, *N. F.*

CHROMII TRIOXIDUM. U. S. (Br.)

CHROMIUM TRIOXIDE Chrom. Triox. [Acidum Chromicum, Pharm. 1890, Chromic Acid, Chromic Anhydride]

(ȼhrō'mĭ-ī trī-ŏx'ĭ-dŭm)

"It contains not less than 95 per cent. of CrO_3 (100.00). Preserve it in glass-stoppered bottles. Caution: Chromium Trioxide should not be brought into contact with organic substances, as serious accidents are liable to result." *U. S.* "Chromic Anhydride, CrO_3, may be obtained by the interaction of sulphuric acid and potassium bichromate. It should be preserved in well-stoppered bottles." *Br.*

Acidum Chromicum, *Br.*, Anhydrous Chromic Acid, Acide Chromique Cristallisé, *Fr. Cod.;* Acidum Chromicum; *P. G.;* Chromsäure, *G.;* Anidride cromica, Acido cromico, *It.;* Acido cromico, *Sp.*

This is not a true acid, but an acid anhydride. It may be obtained by the process official in the former British Pharmacopœia: "Bichromate of Potassium, 30 ounces (av.); Sulphuric Acid, 57 fluidounces (Imp. meas.); Distilled Water, a sufficiency. Dissolve the bichromate of potassium in a mixture of 50 fluidounces (Imp. meas.) of the water and 42 fluidounces (Imp. meas.) of the acid. Set aside for twelve hours, and decant the liquor from the crystals of acid sulphate of potassium that have separated. Heat the liquor to about 85° C. (185° F.), and add the remainder of the acid, and water sufficient to just redissolve any crystals of chromic acid that may have been formed. Allow to cool, collect and drain the crystals, and dry them on porous tiles at a temperature not exceeding 37.8° C. (100° F.) in an air-bath. From the mother liquor more crystals may be obtained on evaporation." *Br.* 1885.

This process yields crystals which are more or less contaminated with sulphuric acid. Vulpius (*A. Pharm.*, 1886, p. 964) shows that commercial chromium trioxide sometimes contains as much as 7 per cent. of sulphuric acid, and that pure chromium trioxide is not scarlet in color, but dark brown-red and steel-glistening, and not deliquescent in ordinary air.

The best yield of pure crystals is said to be according to the method of Zettnow (*Pogg. Ann.*, cxliii, 471), in which 300 Gm. of potassium dichromate are mixed with 500 mils of water, and 420 mils of concentrated sulphuric acid added, and the mixture allowed to stand for twelve hours in order that the acid potassium sulphate may crystallize out. The mother liquor is then heated to from 80° to 90° C. (176°–194° F.), and 150 mils of sulphuric acid added, together with enough water to dissolve the crystals of trioxide which at first separate out. After standing for twelve hours the liquid is poured off from the crystals which have separated, and a second and a third crop may be obtained by concentration. The crystals, having been drained upon a porous plate and washed with pure nitric acid, sp. gr. 1.46, are dried in a current of warm air. For a method by Duviller, in which barium chromate is treated by nitric acid, and chromium trioxide crystallized out of the mother liquor, see *A. J. P.*, 1873, p. 23.

Properties.—Chromium trioxide, as ordinarily seen in commerce, is in the form of anhydrous, acicular crystals, of a brilliant crimson red color and an acid metallic taste, deliquescent, and very soluble in water, forming an

orange-red solution; but according to Kebler there may also be found in commerce an impure "chromic acid" made by mixing a solution of sodium dichromate with sulphuric acid and drying the product; it sometimes contains 60 per cent. of acid sodium sulphate (*Am. Drug.*, 1901, 344). The requirements of the U. S. Pharmacopœia IX are that even traces of sulphuric acid shall be absent, and that the color of the crystals be not scarlet. "Chromium Trioxide occurs as small, needle-shaped crystals or rhombic prisms, of a dark purplish-red color and metallic luster; odorless; destructive to animal and vegetable tissues; deliquescent in moist air. One Gm. of Chromium Trioxide dissolves in 0.6 mil of water at 25° C. (77° F.); also in 0.5 mil of boiling water; when brought into contact with organic solvents (*e.g.*, alcohol), decomposition takes place, sometimes with dangerous violence. When Chromium Trioxide is heated, it darkens, and finally becomes black, but the color is restored on cooling. At about 193° C. (379.4° F.) it fuses to a reddish-brown liquid, which, on cooling, forms a dark red, brittle mass (often enclosing cavities filled with crystals), furnishing a scarlet powder. Above 250° C. (482° F.) it begins to decompose into green chromic oxide and free oxygen, and, after protracted heating, leaves a residue of chromic oxide. When warmed with hydrochloric acid, chlorine is evolved. A solution of 1 Gm. of Chromium Trioxide in 100 mils of distilled water, previously acidulated with 3 mils of hydrochloric acid, is not rendered turbid within one minute on the addition of 1 mil of barium chloride T.S. (*sulphuric acid*)." *U. S.*

"Crimson acicular crystals, very deliquescent, inodorous, acting corrosively on the skin. Very soluble in *water* and in *ether*. Strongly heated it first melts and then evolves oxygen, leaving, after heating to redness, a green residue, which yields little or nothing to *water*. Warmed with *hydrochloric acid*, chlorine is evolved. In contact with relatively small proportions of *alcohol* (90 per cent.), *ether, glycerin*, or certain other organic substances, sudden combustion or explosion may ensue. When 4 grammes are dissolved in a mixture of 20 millilitres of *water* with 10 millilitres of *hydrochloric acid*, 5 millilitres of *solution of barium chloride* added and the mixture filtered, the filtrate yields no further precipitate on the addition of more of the reagent (limit of sulphates)." *Br.*

Chromium trioxide at a heat above the melting point, gives off half its oxygen, and is converted into the green sesquioxide, Cr_2O_3. It is a powerful oxidizing and bleaching agent, and gives up its oxygen with great facility to organic matter. The oxidation of weaker alcohol is attended with the production of aldehyde, recognized by the odor; that of stronger alcohol, by inflaming.

"**Assay.**—Dissolve about 1 Gm. of Chromium Trioxide, accurately weighed in a stoppered weighing-bottle, in sufficient distilled water to make a volume of 100 mils. Mix 15 mils of this solution with 3 mils of hydrochloric acid and 2 Gm. of potassium iodide in a glass-stoppered container, agitate the mixture, allow it to stand for five minutes, then dilute it with 100 mils of distilled water and titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 95 per cent. of CrO_3. Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.003333 Gm. of CrO_3. Each gramme of Chromium Trioxide corresponds to not less than 285.0 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

Uses.—In dilute solution chromium trioxide is a powerful coagulant of albumen and is therefore astringent. In more concentrated solution because of its oxidizing power it destroys all forms of tissue and is a rapid and powerful caustic. It is also an active germicide, Dougall (*L. L.*, Dec. 16, 1871) having found it to surpass phenol; according to Koch a 1 per cent. solution is sufficient to destroy anthrax spores after two days' exposure. By virtue of its oxidizing effect it destroys decaying organic matter, combining with and neutralizing the ammonia and decomposing hydrogen sulphide, thereby acting as a deodorizant.

As a caustic the liquid formed by the spontaneous deliquescence of the crystals may be used; it is most frequently applied by means of a glass rod.

Much care should be exercised in the use of this agent as it is a powerful poison both because of its local irritant effect and its systemic action. A single drop of the saturated solution taken internally has caused violent symptoms and fatal results have followed the too free external use of the drug. (See Shaw, *Virginia Med. Semi-monthly*, 1901, v.)

In dilute solution (5 per cent.) it is used as an antiseptic and astringent wash in *leucorrhea, ozena*, and *hyperidrosis*. In the Prussian army it has been found useful as a foot wash for preventing *sweating of the feet* and to harden the skin. In more concentrated solution it is used as a caustic for the removal of *warts, syphilitic condylomata, nasal, polypi*, and other foreign growths.

Although chromium oxide has not been used internally in medicine Kolipinski (*Monthly Cyclopedia of Pract. Med.*, Sept., 1908) asserts that *chromium sulphate* is a valuable remedy in the treatment of various chronic nervous diseases as *alcoholism, neurasthenia, locomotor ataxia, exophthalmic goiter*, etc. He administers it in doses of from one to eight grains (0.065–0.5 Gm.).

Those whose work brings them in contact with chromic acid or its salts, according to Hermann (*M. M. W.*, April 2, 1901) often suffer with lesions, the result of the local irritant action of these compounds either upon the mucous membrane of the respiratory tract or upon the skin. In a large number of cases there was ulceration of the nasal mucosa eventually with perforation of the septum while other patients developed

bronchitis, eczema, gastritis, or other inflammatory disorders.

Dose, of chromium trioxide, should not exceed one-fourth of a grain (0.016 Gm.). It is very rarely, if ever, used internally.

CHRYSAROBINUM. U. S., Br.

CHRYSAROBIN Chrysarob.

(ĕhrĭs-ą-rō-bĭ'nŭm)

"A mixture of neutral principles extracted from Goa powder, a substance found deposited in the wood of *Vouacapoua Araroba* (Aguiar) Druce (Fam. *Leguminosæ*). Preserve it in well-closed containers, protected from light." *U. S.* "Chrysarobin is a mixture of substances extracted from Araroba by hot benzene. It consists of a definite chemical compound, $C_{15}H_{12}O_3$, also known as pure chrysarobin, or chrysophanolanthranol, associated with certain other substances of similar composition." *Br.*

Chrysarobine, *Fr.*; Chrysarobinum, *P. G.*; Chrysarobin, *G.* Crisarobina, *It.*

The British Pharmacopœia recognizes under distinct headings Crude Chrysarobin (Goa Powder or Araroba) and the Purified Chrysarobin. (See *Araroba,* p. 182.)

Properties.—"Chrysarobin is a brownish to orange-yellow, micro-crystalline powder, tasteless, odorless, and irritating to the mucous membrane. One Gm. of Chrysarobin dissolves in 385 mils of alcohol, 12.5 mils of chloroform; 16 mils of ether, 30 mils of benzene and in 180 mils of carbon disulphide at 25° C. (77° F.); very slightly soluble in water, and in boiling water; it dissolves in solutions of the fixed alkali hydroxides, producing a red liquid. It dissolves in sulphuric acid, producing a deep red solution. On pouring this liquid into water, Chrysarobin is deposited unchanged. Incinerate about 0.5 Gm. of Chrysarobin; not more than 0.25 per cent. of ash remains. Mix about 0.001 Gm. of Chrysarobin with 2 drops of fuming nitric acid; a red mixture is produced, which turns violet-red on the addition of a few drops of ammonia water (distinction from *chrysophanic acid,* which produces a yellow liquid). Boil about 0.1 Gm. of Chrysarobin with 20 mils of distilled water and filter; the filtrate is neutral to litmus and is not changed in color by a few drops of ferric chloride T.S. (*chrysophanic acid*)." *U. S.*

"A light, microcrystalline, yellowish powder; inodorous; tasteless. Entirely soluble in hot *chloroform* and in hot *benzene,* almost entirely soluble in hot *alcohol* (90 per cent.), partially and sparingly soluble in *petroleum spirit,* almost insoluble in *water.* Almost entirely soluble in hot *solution of sodium hydroxide,* with production of a deep brownish-red color. Shaken with *solution of ammonia* the liquid slowly becomes violet. About 1 milligram mixed on a white tile with a drop of *fuming nitric acid* produces a brownish-red liquid, becoming violet on the addition of excess of *solution of ammonia.* Melts when heated, giving off yellow fumes. Ash not more than 1 per cent." *Br.*

Chrysarobin in alkaline solution takes up oxygen readily, even from the air, and changes into chrysophanic acid according to the reaction:

$$C_{30}H_{26}O_7 + 4O = 3H_2O + 2C_{15}H_{10}O_4$$

The difference in physical properties between chrysarobin and chrysophanic acid is well described by Andouard. (See *Proc. A. Ph. A.,* 1895, 864.) When chrysarobin is distilled with zinc dust it yields *methyl-anthracene,* $C_{15}H_{12}$. Liebermann has since established clearly the relationship of chrysarobin to chrysophanic acid, as the latter is a dioxymethyl-anthraquinone, the former is a reduced quinone. Hence its affinity for oxygen, as the reduction products of the quinone class almost always tend to absorb oxygen and again go back to their original condition. Liebermann, in observing the chemical relationship of chrysophanic acid to commercial alizarine and purpurine, was led to study their reduction products (or leuco-compounds), and so discovered a class known as *anthrarobins,* having medicinal properties similar to chrysarobin. (See *Anthrarobin,* Part II.)

Hesse (*Ann. Ch. Ph.,* 1912, p. 388) found that chrysarobin is a complex body containing at least five different substances, namely chrysophanol-anthranol, its methyl ether emodinol and its methyl ether, and chrysarobol. Of these chrysophanol-anthranol is the one to which the drug owes its characteristic properties. This work has been confirmed by Tutin and Clewer (*Tr. Chem. Soc.,* 1912), but the latter find other constituents in addition.

Lenirobin, made by the action of acetic acid on chrysarobin, and described as a tetracetate, and *Eurobin,* the triacetate, are recommended as substitutes for chrysarobin, having the advantage of not staining linen indelibly. (*M. R.,* 1898, 466.)

Uses.—When taken internally in sufficient amount, chrysarobin acts as a decided gastro-intestinal irritant, producing large, very watery, brownish stools, and repeated vomiting without much nausea; it has, however, failed to secure a place as an internal remedy. Chrysarobin has long been used in South America and India as a remedy in skin diseases, but the attention of the general profession was first called to it in 1874 by Sir Joseph Fayrer. It is a remedy of the greatest value in the treatment of *psoriasis* and is also of service in chronic *eczema.* Schamberg, Kolmer and Raiziss (*Jour. of Cutaneous Dis.,* 1915, xxxiii) in an elaborate research on its mode of action reach the conclusions that chrysarobin is without germicidal properties and that its beneficent effects are probably due to its chemical affinity for the keratin elements of the skin, the drug abstracting the oxygen for its oxidation, which takes place simultaneously with this union, from the epithelium.

It may be applied in the form of an oint-

ment with good success, although this method of application has the objection of staining the clothing. For this reason a number of dermatologists prefer the solution in collodium, which may be prepared by dissolving a drachm of chrysarobin in a fluidounce of the official flexible collodion. This is painted over the lesions with a camel's hair brush and after it is thoroughly dried the film may be coated with plain collodium as a further protection against staining the clothing. Another method of applying the drug is to dissolve it in chloroform in the proportion of one to two drachms to the ounce. This solution is painted on the skin, the chloroform evaporating and leaving a thin film of chrysarobin behind. Kossobudskji highly recommends in the treatment of *hemorrhoids* an ointment containing twenty-five grains of chrysarobin, nine grains of iodoform, and eighteen grains of extract of belladonna to the ounce of petrolatum. Benzin is said to be useful for removing the stains caused by chrysarobin.

Dose, official, one-half grain (0.032 Gm.).

Off. Prep.—Unguentum Chrysarobini, *U. S., Br.*

CIMICIFUGA. U. S.

CIMICIFUGA Cimicif. [Black Cohosh, Black Snakeroot, Macrotys]

(cim-ĭ-cif'ū-gą)

"The dried rhizome and roots of *Cimicifuga racemosa* (Linné) Nuttall (Fam. *Ranunculaceæ*), without the presence or admixture of more than 2 per cent. of stems or foreign matter." *U. S.*

Cimicifugæ Rhizoma, *Br.*, 1898, Acteæ Racemosæ Radix; Cohosh; Macrotys; Rattleroot; Squaw Root; Rattle Snake Root; Bugbane; Rattle Weed; Richweed; Bugwort, Rattletop; Racine d'Actée à Grappes, *Fr.*; Schwarze Schlangenwurzel, *G.*

Cimicifuga was dismissed from the Br. Pharm., 1914.

Cimicifuga racemosa is a tall stately plant, having a perennial root, and a simple herbaceous stem, which rises from four to eight feet in height. The leaves are large, and ternately decompound, having oblong-ovate leaflets, incised and toothed at their edges. The flowers are small, white, and disposed in a long, terminal, wand-like raceme, with occasionally one or two shorter racemes near its base. The calyx is white, four-leaved, and deciduous; the petals are minute, and shorter than the stamens; the pistil consists of an oval ovary and sessile stigma. The fruit is an ovoid capsule containing numerous flat seeds. The plant grows in shady or rocky woods from Southern New England to Wisconsin and southward, flowering in June and July. The name Cimicifuga is derived from the Latin *Cimex,* bug; and *fugare,* to drive away.

Properties.—It is officially described as follows: "Rhizome horizontal, more or less branching, from 2 to 12 cm. in length, and from 1 to 2.5 cm. in thickness; externally dark brown, slightly annulate from circular scars of bud scale-leaves, the upper surface with numerous stout, erect or somewhat curved branches terminated by deep, cup-shaped scars, each of which usually shows a distinct radiate structure; inferior and lateral portions with numerous root-scars and a few short roots; fracture horny; internally whitish and mealy or dark brown and waxy, bark thin, wood distinctly radiate and of about the same thickness as the pith; odor slight; taste bitter and acrid. Roots somewhat cylindrical or obtusely quadrangular, from 1 to 3 mm. in thickness, externally dark brown, longitudinally wrinkled; fracture short; internally bark dark brown, wood yellowish, 4 to 6-rayed. Under the microscope, sections of the rhizome of Cimicifuga show a yellowish-brown suberized epidermis, a cortex made up of about 30 layers of starch-bearing parenchyma cells; the fibro-vascular bundles collateral, the xylem consisting of tracheæ with bordered pores, and resembling tracheids in that the ends are rather acute; wood-fibers numerous, thin-walled, strongly lignified and with simple, oblique pores, the bundles separated by starch-bearing parenchyma strands from 5 to 30 cells wide; pith cells numerous, resembling those of the cortex. Under the microscope, sections of the root of Cimicifuga show a hairy epidermis, which becomes suberized in older roots; the cortex shows about 12 rows of starch-bearing parenchyma cells; endodermis distinct; fibro-vascular bundles 4 to 6, showing in older roots as separate collateral bundles. The powder is light to dark brown; starch grains numerous, single or compound, the individual grains spherical or more or less polygonal, each with a somewhat central cleft, from 0.003 to 0.015 mm. in diameter; fragments showing tracheæ with bordered pores and lignified wood-fibers; irregular, yellowish-brown fragments of suberized epidermis made up of more or less tabular cells, sometimes elongated and considerably thickened. Cimicifuga yields not more than 10 per cent. of ash." *U. S.*

For a detailed description of the microscopic character of the root, see *A. J. P.*, 1884, 460; also 1895, 121; Holm., *M. R.*, 1911, p. 6.

The roots "exhibit in transverse section from three to five wedge-shaped wood-bundles, separated by as many broad medullary rays. Both rhizome and roots are blackened by *test-solution of ferric chloride* (presence of tannic acid)." *Br.*, 1898.

The odor, though not strong, is peculiar and rather disagreeable, and is gradually lost with age. The drug of commerce is likely to be unintentionally admixed with other species of *Cimicifuga* and *Actæa.* Cimicifuga yields its virtues to boiling water.

Tilghman found gum, starch, sugar, resin, wax, fatty matter, tannic and gallic acids, a black coloring matter, a green coloring matter, lignin, and salts of potassium, calcium, magnesium, and iron. (*A. J. P.*, vi.) It no doubt also contains, when fresh, a volatile principle,

with which its virtues may be in some degree associated. Davis separated by distillation a small proportion of volatile oil having decidedly the peculiar odor of the root. He also found albumen, extractive, and silica. The sugar noticed by him was of the uncrystallizable variety, and the resin of two kinds, one soluble in alcohol but not in ether, the other soluble in both these menstrua. (*A. J. P.*, xxxiii.) A crystallizable principle has been obtained by T. Elwood Conard from a strong tincture of the root by treating with solution of lead subacetate to precipitate resin, tannin, and coloring matters, then filtering, and precipitating the lead by hydrogen sulphide in excess, and allowing the tincture to evaporate spontaneously; and, finally, having treated the residuary powder with petroleum benzin, afterwards washing it with water, dissolving it to saturation in strong alcohol, and treating the solution with alumina. The mixture was allowed to evaporate to a dry mass, which was nearly exhausted with alcohol. The solution, being allowed to evaporate, left behind a crystalline mass, somewhat resembling alum. This substance has little taste, on account of its extreme insolubility in the saliva, but in alcoholic solutions has very strongly the acrid taste characteristic of the fresh root. The crystals are very soluble in cold, and more so in hot alcohol, soluble also in chloroform, and slightly so in ether. They are fusible and inflammable. They are neutral, possessing neither acid nor alkaline properties. Their effects on the system were not determined. (*A. J. P.*, 1871.) L. F. Beach (*A. J. P.*, 1876) obtained from commercial resin of cimicifuga (the so-called cimicifugin or macrotin) a crystalline principle by Conard's process. M. S. Falck (*A. J. P.*, 1884) found in the juice of the fresh plant a crystalline principle resembling the principle announced by Conard. On the other hand, neither F. H. Trimble (*A. J. P.*, 1878) nor Warder and Coblentz were able to obtain a crystalline principle, while C. S. Gallagher obtained crystals of cane sugar from the fluidextract. (*A. J. P.*, 1887.) In view of these facts, it would appear that the active principle is a resinous amorphous body. (See *Drugs and Medicines of North America*, vol. i.) Finnemore reports on the chemical examination of the rhizome of cimicifuga. A systematic examination has resulted in the isolation and identification of *isoferulic acid*, also a minute quantity of an acid whose melting point was unaffected by admixture with salicylic acid. Palmitic, oleic, and other unsaturated acids, and phytosterol, are also present, and distinct reactions for alkaloids have been found, but the amount present is very small. (*P. J.*, 1910, 31 (85), pp. 142–144, 178.)

Uses.—In 1831 cimicifuga was introduced to the notice of the profession by Young. In overdoses it is said to cause general relaxation, vertigo, tremors, decided reduction of the pulse; occasionally it causes vomiting, but its emetic action is never violent, and is probably simply the result of a mild gastric irritation. It certainly, in large doses, produces giddiness, with intense headache and prostration. It has been found by R. Hutchinson to cause in frogs complete anesthesia by a direct action upon the sensory side of the spinal cord. The same observer noted that toxic doses produce in mammals slowing of the pulse and fall of the arterial pressure, results which appear to be due in part to a direct depressant action upon the heart muscle or its ganglia, in part to a paralysis of the vasomotor center. Clinical experience has shown this drug to be a useful remedy in the treatment of *chorea*. It has also been employed, though with less certainty of benefit, in *chronic rheumatism, urticaria, neuralgia,* and *dysmenorrhea*. It is also asserted to act as a specific in *tinnitus aurium*.

In *chorea* it is necessary to give large doses. The proper method of administration is to start with about fifteen minims of the fluidextract three times a day, increasing one minim daily until the occurrence of frontal headache or improvement in the condition. The practitioners calling themselves eclectics use, under the name of *cimicifugin*, or *macrotin*, an impure resin obtained by precipitating a saturated tincture of the root with water; dose, a grain or two (0.065–0.13 Gm.). (See *N. J. Med. Rep.*, viii, 247.)

Dose, of powdered cimicifuga, five to thirty grains (0.3–2.0 Gm.).

Botanical History.

Though the Peruvian bark was introduced into Europe so early as 1640, it was not until the year 1737 that the plant producing it was known to naturalists. In that year La Condamine, on a journey from Quito to Lima, through the province of Loxa, had an opportunity of examining the tree, of which, upon his return, he published a very complete description, with plate, under the name *Quinquina*, stating that three species were recognized. (*Mém. Ac.*, Paris, 1738, p. 226.) Four years later, Linné proposed a new name, *Cinchona*, in honor of the Countess of Chinchon, who first made the bark known in Europe. Linné recognized but one species, which he called *C. officinalis*, and this continued for a long time to be recognized by the Pharmacopœias as the only source of the Peruvian bark of commerce. But a vast number of plants belonging to the Linnæan genus Cinchona were in the course of time discovered; and the list became at length so unwieldy and heterogeneous that botanists were compelled to distribute the species into several groups, each constituting a distinct genus, and all associated in the natural family of Rubiaceæ.

For our knowledge of these plants as they existed naturally, we are chiefly indebted to the following botanists, besides La Condamine, of whom we have before spoken: Joseph de Jussieu, who, in the year 1739, explored the country about Loxa, and gathered specimens which still exist in the cabinets of Europe; Mutis, who in 1772 discovered Cinchona trees in Colombia, and afterwards, aided by his pupil, Zea, made further investigations and discoveries in the same region; Ruiz and Pavon, who in 1777 began a course of botanical inquiries in the central portions of Lower Peru, and discovered several new species; Humboldt and Bonpland, who visited several of the Peruvian bark districts, and published the results of their observations after 1792; Pöppig, who travelled in Peru so late as 1832, and published an account of his journey about the year 1835; Weddell, whose researches in Bolivia are so well known and have been productive of valuable information in relation to the Calisaya bark and allied species; while Karsten, Caldas, Martius, Ledger, Markham, and other intrepid explorers have in later times largely added to our information. At the present time (1917) thirty or forty more or less clearly defined species of Cinchona are recognized. Of all of these probably but four with their cultivated hybrids yield the Cinchona Bark of commerce. The principal sources of information bearing on this phase of the subject are the several reports of the plantations in Java, India, and Jamaica. Howard's *Quinology of the East Indian Plantations*, Markham's *Peruvian Bark*, Kuntze's *Arten, Hybriden und Cultur der Chininbäume*, Hooper in the *Pharmacographia Indica*, several contributions by Trimen to the *Tropical Agriculturist*, and Rusby in the *Pharmaceutical Record*, October, 1887. The literature of the cinchona hybrids is hopelessly confused by the same name being frequently used by different authorities for the different hybrids and the one hybrid having various names. Thus, *C. robusta* of Trimen is known in Ceylon as *C. lanosa*, and in the Neilgherry Hills as *C. magnifolia*, also as *C. pubescens*.

C. Calisaya Weddell, is tall, usually surpassing those about it, the trunk often more than two feet in diameter. Leaves petiolate, the blade ovate-oblong to slightly obovate, 7 to 17.5 cm. long by 2.5 to 7 cm. broad, obtuse, the base acute or slightly attenuated, very thin, smooth, and, especially below, with a satiny luster, above dark green, below emerald-green or deep purple-green, scrobiculate, the glands scarcely visible above. Stipules oblong, about equalling the petioles, very smooth, very obtuse. Panicles ovate to subcorymbose. Calyx pubescent, with a cup-shaped limb and short triangular teeth. Corolla rose-colored (in cultivation often white or nearly so), the tube cylindrical and about 8 mm. long, the laciniæ more deeply colored, the edges white-hairy. Stamens included. Capsule ovate, scarcely as long as the flowers. Seeds elliptical lanceolate, the margin irregularly fimbriate-toothed. Bolivia and Southern Peru, 4000 to 6000 feet. Source of the Calisaya or Yellow Bark. The species presents many forms, and two varieties are recognized.

C. Ledgeriana Moens., formerly recognized as a variety of *C. Calisaya*, differs from the type chiefly in its thicker, narrower, oblong leaves, with attenuate base, often bluish-green below. It yields a thick and remarkably rich bark, and is probably the most valued of all the cinchonas. This species was named in honor of Ledger, who first brought seed of this species from Bolivia.

C. succirubra Pavon, Mss. (Howard in *P. J.*, Oct., 1856, p. 209, with a figure). Extreme size even greater than that of the last. Branches silvery. Petiole pubescent, leaf ovate to oval, acute with a very short point, the base more or less narrowing, often 6 by 9 inches, dark green and smooth above, below paler and pubescent to a variable degree, especially on the veins, not scrobiculate, the margin slightly revolute. Stipules entire, oblong, obtuse, subamplexicaul. Flowers much as in the last, but rather smaller. Fruit lanceolate. Western slopes of Mt. Chimborazo. The source of the Red Bark.

C. officinalis Hooker fil.—Petioles smooth, cylindrical, and, like the veins, reddish; blade 10 to 12.5 cm. long, varying from broadly oval to lanceolate, acute at both ends, the margins usually recurved, smooth and deep green above, paler, but bright green below, scrobiculate, the principal veins pubescent. Stipules equalling the petioles, ovate, acute, entire, pubescent. Flowers and fruit much as in *C. Calisaya*. Widely distributed in the equatorial Andes, at an elevation of from 5000 to 7500 feet. The source of the barks known as Pale, Crown,

Loxa, Cuenca, and Huanuco. This is the original species, upon which the genus *Quinquina* or *Cinchona* was founded. All things considered, it is, perhaps, to be regarded as the principal species of the genus and its variability is extreme.

The specific variations produced by hybridization in the above characters may not be here considered, though it may be stated that they are entirely characteristic. The parentage of a hybrid is ordinarily fully and strongly indicated in its appearance. As a rule, also, the alkaloidal yield takes a mean between that of the parents, but sometimes this is conspicuously not the case. Goris and Reimers (*Trav. Lab. Nat. méd. Ecol. supe. Pharm.*, in *Bot. Centralbl.*, 1906, p. 462) pointed out the use of *Cinchona robusta* Trimen as a collective name for all hybrids of *C. succirubra* and *C. officinalis*. Rosenthaler gives an account of the structural characteristics and alkaloidal content of *C. robusta* and other cinchona hybrids produced by grafting. (*B. P. G.*, 1908, p. 126.)

Geographical Distribution.

The genuine Cinchona trees are natives exclusively of South America. In that continent, however, they are widely diffused, extending from the 19th degree of south latitude, considerably south of La Paz, in Bolivia, to the mountains of Santa Marta, or, according to Weddell, to the vicinity of Caracas, on the northern coast, in about the 10th degree of north latitude. They follow, in this distance, the circuitous course of the great mountain ranges, and for the most part occupy the eastern slope of the second range of the Cordilleras. Except northward from Guayaquil, both the western slope and the plateau are entirely too dry or too cold for these plants, which require a moderate and equable temperature and an abundant and fairly constant supply of water. Irrigation cannot supply the place of a humid climate, for the atmosphere as well as the soil must be well charged with moisture. A certain amount of dry weather is, however, required for the ripening of the capsules. Free drainage is an important condition. Cross and others, who have personally inspected the region in the Andes where the best barks are obtained, have found the Cinchona trees only on the well drained slopes, and never on wet ground. With regard to temperature, Cross found that in the region of the *C. officinalis* the variation was from 1.1° to 21.1° C. (34°–70° F.), a fall below 40° or a rise above 65° being rare, and the mean range being from 45° to 60°.

The limits of altitude and climatic conditions are closely drawn. In the most southern districts, the trees descend to about 2500 feet, while in the warmest regions they scarcely ascend to the 10,000-foot level. The individual species are for the most part rigidly restricted as to altitude and latitude, and, indeed, it has not always been found easy to detect the climatic conditions which would cause one species or variety to thrive while another very near it would languish. This is especially true of the more valuable forms.

It is to be noted that at present the stocks of wild barks have been enormously reduced, as detailed under Commercial History. Indeed, in certain sections, as the Calisaya district, the tree was practically exterminated in the wild state, so far as relates to a bark supply. From the far interior, however, occasional bales of wild Calisaya have been received. The low price of cultivated bark since 1885 has resulted in checking the destruction of the wild trees, which have begun again to multiply, so that they may possibly become once more common or even abundant. The Crown Bark region of Ecuador is still fairly productive, and in Colombia and Venezuela there are vast supplies of more or less inferior barks which await some favorable change in the market—never very likely to take place—that will render their collection profitable. Even at present a limited and irregular supply of one of these barks is furnished. With the exceptions here noticed, our present supplies of bark are entirely the product of cultivation, to which, therefore, we must give our chief attention.

Cultivation and Production.

The alarming prospect of the failure of the supply of Cinchona bark (see Commercial History) induced Europeans, about the middle of the nineteenth century, to turn their attention to the possibility of introducing the trees to cultivation. So early as 1737, La Condamine had collected a large number of young plants, with a view of conveying them to Europe; but, after having descended the Amazon in safety for more than a thousand leagues, they were washed overboard, near the mouth of that river, from the boat containing them, and were all lost. After this failure, though the idea of transplanting the Cinchonas was occasionally suggested, nothing was done until 1846, when Weddell, now celebrated for his successful exploration of the region of the Calisaya bark, sent some seeds to France, which were planted with success in the Jardin des Plantes, and thus supplied some of the conservatories of Europe with specimens of the plant. But the first successful effort with a view to great practical results was made in 1853 by the Dutch government, by which Hasskarl, formerly superintendent of the Botanical Garden in Java, was sent to South America on this important mission. Five hundred Calisaya seedlings were forwarded by him directly across the Pacific to Batavia, which they reached before the close of 1854. From these, and from seeds obtained from other sources, which were planted in the mountains of Java, in sites selected for their supposed conformity in climate with the native locality of the Cinchona, have sprung the most important plantations now in existence.

Stimulated by the suggestions of Royle, and by the partial success of the Dutch, the English

government engaged, in 1859, the services of Clements R. Markham, who proceeded to Bolivia, in South America, and, after almost incredible hardships, arising partly from the nature of the country and partly from the jealousy of the native authorities, succeeded in collecting and transmitting to England upwards of 400 Calisaya plants. Most of these, however, were so much injured on their way from England to India, by the excessive heat of the Red Sea, that very few, on their arrival in Hindostan, had sufficient life remaining to grow when planted. Happily, the deficiency was supplied by seeds of *C. Calisaya* sent from Java, to Calcutta, at the request of the English Governor-General. While Markham was in Bolivia, other agents were collecting other species in Peru and Ecuador, whence seeds of the pale and red bark Cinchonas reached India, and, being planted in the selected sites, proved to be very productive.

Careful attention to the conditions of growth enumerated under Geographical Distribution was found essential in the selection of sites for the plantations. Those selected were near the Sanitary Station of Ootacamund in the Neilgherry Hills of Southern India, at heights varying from 5000 to 7450 feet. These positions unite the peculiar characters of the native regions of the Cinchonas in the Andes, not only as regards elevation and latitude, but also as to atmospheric moisture. Other sites were selected for experimental plantations, and since the first introduction of the Cinchona trees, their culture has been extended to various points from Hakgalla, in the island of Ceylon, to the Himalaya Mountains,—as in the Wynaad, the Coorg, the hills of Travancore, and especially at Peermede in the Presidency of Madras; in Sikkim and Darjeeling in the Presidency of Bengal; at Lingmulla in the Presidency of Bombay; and in the valley of Kangra in the Punjab,—from the southern to the northern extremity of British India. Outside of India and Ceylon, culture by the British has been undertaken in the West Indies, particularly Jamaica, in Guiana, and in the Fiji Islands. The first plants taken by Weddell from Peru to Paris all perished, but the French afterward established plantations in the Isle of Bourbon, at Guadeloupe, and in Algiers, none of which are known now to exist. The Portuguese have established plantations upon the west coast of Africa, and these now yield considerable quantities of bark. Very extensive plantations have been formed, chiefly by the Germans, in Bolivia. A rather large plantation in Colombia is now old enough to be productive. In Mexico and Central America various attempts to introduce the industry have been made. The question of introducing it into the United States has frequently been raised, but it may be stated that there is no spot in North America where the conditions warrant the slightest hope of success in this direction.

The history of Cinchona cultivation affords a striking illustration of the importance of government aid in the establishment of a new industry of this kind. The early and repeated disappointments and failures, owing to the natural obstacles in the way of securing stocks, and to an almost total ignorance of the conditions determining the successful propagation and growth of the plant, and the composition of its bark, were such as to have discouraged the most hopeful of private enterprises. Repeated and expensive expeditions were necessary before the first transplantings were accomplished, and these stocks were preserved and propagated only through the instrumentality of well appointed public gardens and plantations. In Java, after these early difficulties had been surmounted and success apparently attained, it was found that owing to cross fertilization much of the progeny was entirely worthless, and the work of propagation had to be begun anew. The same difficulty was encountered elsewhere, and the slow and expensive method of propagation by cuttings was largely resorted to. In Ceylon the public were slow to become interested, and the officials were obliged not only to give away the young plants, but to solicit experiments with them as a personal favor. In Jamaica a hurricane visited the young and flourishing plantations and almost completely destroyed them. But at length, in spite of all, not only were thriving and permanent government plantations established, but private capital and enterprise upon a vast scale were enlisted. The question of commercial success is dominated not simply by climatological surroundings, but also by the price of labor. It is stated that both in India and Java the natives who work in the cinchona forests are paid from one dollar to one dollar and seventy cents per month, without food, according to the age and sex. The ability to extract the bark upon the spot is capable of largely counterbalancing a lack of market facilities; but it so happens that this advantage also inures to the benefit of the Eastern countries. Originally undertaken in India for the purpose of affording a cheap antiperiodic (the crude alkaloids known as "*febrifuge*" or "*quinetum*") home extraction has become a most important industry, and has assumed various forms. In Java the powdered bark is thrown into a 5 per cent. solution of caustic soda at 50° C. (122° F.) treating this with Java petroleum, separating, treating the petrolic solution with water acidulated with sulphuric acid and evaporating; the result is said to be a quinine containing less than 1 per cent. of cinchonine. (*J. P. C.*, 1901.) It is imported largely into the United States—50,000 kilogrammes a year—but on account of its yellow color is chiefly employed in the making of proprietary medicines rather than tablets. Through the influence of the above conditions the locations of the important industry of Cinchona cultivation have been gradually wrought out, and at present about four-fifths of the cinchona barks of the world, outside of India, are furnished by Java. The first shipment from

Java was of 900 pounds, in 1869. In 1902 it was 14,700,000 pounds and in 1911 over 20,000,000 pounds. India produces annually over 2,000,000 pounds; Ceylon about 400,000 pounds; Portuguese West Africa about 180,000 pounds, and South America 775,000 pounds. Tunmann estimates that the yearly output of cinchona bark is about 10,000,000 kilogrammes, and the production of quinine as about 500,000 kilogrammes. (*Apoth. Zeit.*, 1910, p. 565.)

It is to be remembered that a great part of the Indian product is not exported.

Methods of Cultivation.

The history of Cinchona cultivation teems with evidence as to the difficulty of obtaining pure seeds, owing to the tendency of the plants towards cross-pollination. In every locality where the industry has been established has the disgust of the gardener been excited by the discovery that the plants which he had reared with great care, and upon which he had based great expectations, were contaminated by the admixture of foreign pollen. This was especially true in case of the earlier attempts, before this tendency had become known. Experience at length established the fact that absolute isolation of the seed-trees was essential. One of the curious developments of these experiments was the fact, already referred to, that the value of the progeny was not always assured by the value of its parentage. Some of the hybrids, even when least expected, would develop a surprisingly rich yield; and this tendency has been utilized to develop the most valuable stocks in existence. So certain is it that some of the plants from the best seed will prove worthless, that the careful selection of the seedlings while young is deemed necessary, and in South America, at least, all planting contracts are based upon this expectation, the contractor not being paid for his work until the plants have become old enough to show with certainty the proportion of good plants contained. Both in the selection of the young seedlings and the acceptance of the plantation, the test of identity is found in the leaf. Propagation by cuttings, extensively practised in some localities, has been found too slow and expensive to become general. A thorough preparation of the soil is as beneficial in the case of Cinchona as in that of other crops. Thorough tillage after transplantation is also essential, a free growth of weeds meaning destruction to a large number of the young trees. The cultivation of a secondary crop between the rows of trees is, however, practicable. A large percentage of profit depends upon the selection of a suitable age for collecting the bark. There comes a time when the use of the ground for starting a new crop is more valuable than the gain by permitting the present crop to remain, and after some years an actual deterioration of the bark sets in. This age is not the same for all the trees in the plantation. Several years' difference may occur in the maturing of trees germinated at the same time. In the case of Calisaya it occurs at from six to nine years from seed, and its indication is the "chicken-leg" scaliness of the bark, as described under Classification. The "officinalis" matures somewhat less early. In the Bolivian plantations the most experienced hand is selected as the marker, and the cutters follow him, peeling the trees which he has indicated. How far these careful methods of selection are followed elsewhere, the writer is not informed.

Collection of Bark.

Four principal methods of collecting the bark are in vogue, these being variously modified in different sections. The first is *uprooting*, the most primitive, by which the trees are simply uprooted at the proper age, and the ground replanted. The barks of root, stem, and branches are preserved and marketed separately. The second method is *coppicing*, by which, after peeling a quill from the lower portion of the trunk, the latter is cut a few inches from the ground and the remainder of the stem bark and the branch bark are removed. The "coppice" is formed by a second growth of two shoots from each of the stumps. A second coppice is commonly grown, and this is harvested by uprooting. By the third method, *scraping*, the outer bark is scraped off, leaving the liber untouched. This has been found especially applicable to young trees, in which the second growth of bark is rapidly formed and contains 20 to 30 per cent. more alkaloid than that which has been taken off. It seems to be a general opinion among the planters that scraping checks the growth of the tree after it is five years old, so that from three to five years is the age at which it is best practised. The fourth method is known as *mossing*. It having been noticed that the Cinchona alkaloids, especially in any other form than that of sulphate, were apt, on exposure to the direct light of the sun, to become reddened by the generation of coloring matter, at the expense of the alkaloid, it was a very natural inference that a similar change might take place in the living plant, as a consequence of which the proportion of alkaloids they were capable of producing might be greatly diminished. It was also observed that the bark upon that side of the tree where the sun struck it was less rich than that upon the shady side. To obviate this presumed effect, MacIvor was induced to make the experiment of covering the stems of the growing trees with a layer of moss, so as to completely protect the bark against the influence of sunlight. The result was favorable beyond all expectation, and the yield of alkaloids in the bark thus protected is said to be doubled, tripled, or increased even in larger proportion. A tree can thus be made continuously productive; for if a slip is removed longitudinally from the trunk, from top to bottom, by covering the decorticated portion with moss, the bark is renewed at least as rich as previously in the

alkaloids, while from time to time other strips may be taken, until the whole of the old bark is removed, and the new ready for removal by a repetition of the same process; and the tree is thus preserved indefinitely, probably for the whole normal length of its life. Hooper says that renewed bark is always of greater value than the mossed, and mossed than the natural, so long as the trees are under twenty years old, for it has been found that after that time the bark ceases to thicken, and the alkaloids remain stationary or even decrease. Perhaps twenty years is even too old. The practical difficulty with the process is that it requires skilled workmen, not always attainable, and hence the "coppicing system" still largely prevails in India.

The methods of packing the bark have also undergone important modifications since the early days of cultivation. The extensive adulteration practised when the wild bark brought very high prices led to a demand for it in large pieces which could be readily and quickly examined; hence the appearance of the large *tabla* and *quill* forms, the latter afterwards becoming the standard for the cultivated bark. The bark of the trunk, and sometimes of the branches when very large, is cut into two-foot lengths, and each length removed in a single piece, which in drying rolls up to form a quill. Such peeling can of course be successfully practised only at the appropriate season of the year. The bark or the roots, branches, and dead or dry trunks must be removed by chipping, scraping, or shaving, commonly the latter. The quills, after thoroughly drying, are carefully packed in bales, or preferably in boxes, to avoid breakage, and are marketed in packages of from 100 to 250 pounds. Large quantities of cultivated bark are still marketed in this way, but, increasing competition having lowered prices so that economy in freight has become a very important item, most of the bark is now broken up, and its bulk even reduced by high pressure, and in fact only a trifling amount of wild South American bark comes into commerce. Cultivation has very greatly increased, not only the quantity, but also the quality of bark. For some years, in India the attempt was made largely to increase the general average in total alkaloids rather than in quinine, so as to increase the production of the impure alkaloids which are so largely used as febrifuges in the British East Indies. Of recent years, however, even in India, efforts have been directed to the obtaining of quinine rather than of inferior alkaloids. The barks of Ceylon have always been of poor quality, while those of Java to-day are probably the best that have ever been put upon the market. The effect of the efforts of arborculturists is well shown by the facts that in 1889 the average percentage of quinine in Java bark was 4; in 1893 it had risen to 4.6; while in the five years, from 1900 to 1904 inclusive, the average quinine percentage of all the Java barks sold in the Amsterdam market was 5.37. The result does great credit to Java, for during the early history of her bark enterprise her plantations were stocked with discouraging quantities of poor or even worthless barks, which have been eliminated by the most steady enterprise and patient industry. David Howard presented a comprehensive survey of cinchona barks and their cultivation. (*J. Soc. Ch. Indus.*, 1906, p. 97.) Winkler describes the methods employed in the cultivation of Cinchona in Java, also the manner of collecting the bark and preparing it for market. (*Der Tropenpflanzer*, 1906, p. 222.) Böhringer gives a review of the progress in the cultivation of Cinchona in Ceylon. (*Tropenpflanzer*, 1909, p. 269.) Schneider discusses the possibility of cultivating Cinchona in California. (*W. D.*, 1906, p. 136.)

Commercial History.

The above general history of Cinchona leaves little necessary to be said of its commercial history, except to deduce from the facts already presented certain practical conclusions showing the present conditions of supply and demand, these bearing especially upon our concluding remarks concerning pharmacognosy and classification.

For more than a century after Peruvian bark came into use, it was procured almost exclusively from the neighborhood of Loxa. In a memoir published in 1738, La Condamine speaks of the bark of Riobamba, Cuenca, Ayavaca, and Jaen de Bracomoros. Of these places, the first two, together with Loxa, lie within the ancient kingdom of Quito, at the southern extremity; the others are in the same vicinity, within the borders of Peru.

Towards the end of the eighteenth century, however, the trees were discovered to exist in Colombia, in central Peru, near Lima (whence the name *Lima bark*, at one time applied to the drug) and in Bolivia.

The consequence of these discoveries was a vast increase in the supply of bark, which was now shipped from the ports of Guayaquil, Payta, Lima, Africa, Buenos Ayres, Cartagena, and Santa Marta. At the same time the average quality was probably deteriorated; for, though many of the new varieties were possessed of excellent properties, yet equal care in superintending the collection and assorting of the bark could scarcely be exercised in a field so much more extended. The varieties poured into the market soon became so numerous as to burden the memory if not to defy the discrimination of the druggist, and the best pharmacologists found themselves at a loss to discover any permanent peculiarities which might serve as the basis of a proper and useful classification. More or less perplexity attending the recognition of the barks continued until after the firm establishment of the bark culture and the cheapening of the price, to the exclusion of the worthless varieties, as already described.

One of the most important developments of the modern bark trade is the fixing of the price in accordance with the quality as determined

by assay. The most accurate method of selecting a characteristic sample for assay is a subject which has received much study, without the discovery of any method which does not depend for its value upon the discrimination and care exercised in its employment. The plan which is regarded as the safest, is to take a given weight, say eight ounces, from the inner portion of each package constituting the lot, mix and powder the whole of it, and furnish to applicants the required amount of the resulting powder. If any portion of any bale or bales is damaged, care is taken to add a proportionately large fragment of such portion. The bark is then recorded as containing so many units, a "unit" being each per cent. of quinine contained in a pound of bark. In rich bark the units are of course worth more than in poor, owing to the increased yield of alkaloid for the same cost of manufacture.

In the United States, at least, some difficulty has been experienced by druggists in securing the better grades of bark at regular rates, owing to the activity of the manufacturers in draining the market of the most desirable stock. The finer appearing packages of unbroken bark, having been marketed at greater cost, are necessarily held at higher prices. Possessing no special value for manufacturing purposes, these fall to the share of the druggist, but at higher prices than broken bark of the same richness. This fact has led to the recognition of two distinct classes, known as *manufacturers' bark* and *druggists' bark*. Druggists' bark, though in quills or unbroken pieces, and of a much finer appearance than manufacturers' bark, is on the average, inferior in quinine percentage. The druggists' bark finds its entrance into commerce through various channels but the bulk of the cinchona trade, including practically all that is known as manufacturers' bark, centres in Amsterdam and London; of these marts that at Amsterdam is much the more important. In 1916 there were imported into the United States 3,947,320 pounds of cinchona barks, and 1,791,738 pounds of quinine sulphate and other salts of the cinchona alkaloids. The bark which is sold in Amsterdam comes almost exclusively from Java; that in London from India, Ceylon, and South America. Manufacturers' bark is sold, without respect to its physical characters or place of origin, entirely by its chemical analysis, the buyer in London being furnished with samples of the different lots of the bark sufficient time before the sale to enable him to make his own analysis, while in Amsterdam the percentage of quinine sulphate in any lot is given in the catalogue and often tagged upon the bale.

Formation of the Alkaloids.—In a very careful series of experiments made at the Java governmental cinchona plantations, Lotsy (*Bull. Inst. Botanique Buitenzorg*, 3, 1900) found that the seeds of *C. succirubra* and *C. Ledgeriana* contain no alkaloids, but that these alkaloids appear in the cotyledons shortly after they become green. They exist chiefly in the bark in combination with a tannic acid. Lotsy found that the percentage of alkaloids is ten times greater in young than in old leaves; also that the petioles are richer in alkaloids than is the blade, and that the branch bark contains more than the trunk bark, and that the root bark is practically free from alkaloids. During the active life of the parenchymatous cells of the leaves, wood, and cortex, the alkaloids can always be found in the active protoplasmic contents, but when these cells pass into the inactive condition, are deposited in the cell-walls. The alkaloids found in the leaves are, however, never crystalline, hence it would appear that these organs produce by direct synthesis, probably as the result of the action of cinchonic acid with ammonia, a fundamental alkaloidal base, which probably in the cambium layer of the tree, and during its deposition in the growing bark, is elaborated into the true cinchona alkaloids.

Classification.

Extreme difficulty attended the earlier attempts to classify the Cinchona barks of commerce,—difficulties not probably encountered elsewhere in the Materia Medica. The varieties have, however, been reduced to a very few, and the whole subject decreased greatly in importance by the chemical method of the sale now in vogue. Most of the discarded barks will be found described in previous editions of this work. We find it necessary to enumerate and describe here only the Pale bark, from *C. officinalis*, the Red bark, from *C. succirubra*, the Yellow bark, from *C. Calisaya* and its var. *Ledgeriana*, and the Hard Yellow or Maracaibo bark, and to refer briefly to the hybrid forms. First, a few words concerning the forms in which Cinchona bark occurs. We have (1) the large flat pieces or chips of irregular shape and size,—this referring at present almost wholly to the Maracaibo variety; (2) the small chips or broken bark, referring in large part to the root bark, and to other bark broken for close packing; (3) the shaved bark, referring to some root bark and to stem bark taken from dry stems, but chiefly to branch bark; (4) the quill bark, referring to natural bark taken from the stem and root in quill form, this including the uncultivated pale bark and all the varieties of cultivated bark; and (5) the renewed and mossed bark, which may be of any cultivated variety. The classification of all varieties and forms into druggists' and manufacturers' barks enables us to dispense in great part with a description of some of these forms. The manufacturer cares nothing for form, appearance, or structure, and but little for the variety of his supplies. He is interested wholly in its composition, and this he determines by assay. For this reason most of the broken bark goes to him. The druggist requires the quill or large chip bark; so that the great bulk of the branch bark is also thrown, at low prices, upon the hands of the manufacturer.

As regards the root barks, no classified description is available. In their structure they correspond very closely to the stem barks of the same variety. They can be readily distinguished from the latter by being thinner, having lighter external and darker inner color, greater softness, and twisted or contorted structure. They occur in short, irregular quills or chips, or sometimes as shavings, and contain very much more dust than any other form. Except partly as regards structure, the description of stem barks will not apply to branch barks of the same variety, for the characteristic markings do not appear in the young condition. The branch bark appears in shavings, to the inner surfaces of many of which more or less wood adheres. If the branches were shaved while yet fresh, these shavings will be more or less rolled up and curled; but if dry before being removed, this rolling and curling will not occur. Shaved bark taken from living trees is thin, soft, and brittle, consisting of the outer bark only. The large quills are of uniform length from the same plantation, but not necessarily so from different plantations or different sections. They are commonly from two to three feet in length, but some have been marketed having a length of five feet. Usually they represent the entire circumference of the stem, but occasionally only half of it. In drying they roll up very tightly from one or both edges, and rarely one will be wholly or partly involved in another. The periderm, with all its markings, remains intact, and no other form so well displays the natural appearance as this. Mossed bark differs from natural stem bark in its great thickness and weight, less breadth of the quills, freedom from lichens, very dark color, and rough, corrugated or warty surface. The outer bark or cellular portion bears a greater ratio to the inner or fibrous portion than in natural bark. Renewed bark is lighter, both in color and weight, thinner, soft and brittle, and marked by a very peculiar external smoothness, sometimes very marked indeed. In its general appearance it is strikingly like a root bark, except for the relative straightness of its fibres. Like the mossed bark, it is in narrow, only partly rolled quills or bands, and is entirely free from lichens.

As they differ so greatly among themselves in coloration, lichen-growth, degree and form of exfoliation, structure and consequent fracture, there are but few characters which can be combined in a general description of the Cinchona barks which we consider. The external color varies from light ashy gray to nearly black, the inner varies less in its shades of yellow-brown and red-brown. All are more or less bitter, and most are astringent, but only Loxa bark has a distinctive odor. The fracture is never very long-splintery and never tough. As to structure, the bast fibers are loosely arranged, the radial rows being neither continuous nor very long. The fibers themselves are always unbranched, which distinguishes the true from the false barks, are rather short and obtuse, brittle, and usually easily detached from the bark. Laticiferous ducts and stone-cells may or may not be present. The former become less conspicuous as the bark grows older, so that their relative absence becomes indicative of a stage in which the due proportion of alkaloid should have been acquired.

It may be noted here that by far the greater portion of the alkaloid, particularly quinine, is stored in the outer bark, though that in the inner bark is in a purer state. The latter is not stored in the fibers, but in the cellular tissue between them.

As regards the former classification of barks by color, it referred only in small part to the external color, chiefly to the powder. These colors were never regarded as absolutely characteristic, as the three barks, yellow, red and pale, exhibited gradations by which they mingled at their extremes. Under present conditions, the lines of demarcation have become even more indistinct, and, as a matter of fact, in the market the terms "yellow" and "red" are used with great looseness. It is true that we receive much pure-blooded Yellow Bark, *Ledgeriana* from the East, and *Calisaya* both from there and from South America; but it is also undeniable that much of the bark sold under the several names is of mixed hybrid, and the typical characters are often greatly obscured. The presence in our market of these mixed forms has made the terms even less valuable than they once were, and dealers cannot be found to agree as to the character of many samples. Nevertheless, the occurrence of the typical forms, and appearance in a hybrid of the blended characters, render it desirable to preserve this classification, and to group the new forms around the types.

Yellow or Calisaya Bark. Cinchona Flava.

The official description is as follows: "In quills or curved pieces of variable length, bark from 3 to 5 mm. in thickness, or in small broken fragments or in transversely curved pieces from 3 to 7 mm. in thickness, externally gray, rarely brownish-gray, with numerous intersecting transverse and longitudinal fissures having nearly vertical sides, and usually with patches of foliaceous lichens with their small, brownish-black apothecia; when the outer bark is absent, the color externally is cinnamon-brown; inner surface light cinnamon-brown, finely striate; fracture of the outer bark short and granular, of the inner bark finely splintery; odor faintly aromatic; taste very bitter and somewhat astringent. The powder is reddish-brown; bast-fibers spindle-shaped, yellowish, from 0.3 to 1.35 mm. in length, with thick, strongly lignified, lamellated walls having slit-like, oblique pores; starch grains single or 2- to 5-compound, the individual grains spherical or plano-convex and from 0.003 to 0.015 mm. in diameter; sphenoidal micro-crystals of calcium oxalate numerous. Heat 1 Gm. of powdered Cinchona in a dry test tube; a tarry distillate forms, having a

purplish color and a somewhat granular appearance." *U. S.*

Its lichens are thin and closely adherent, not rendering it shaggy. External markings very characteristic, consisting of a very light longitudinal ridging or none at all, but of numerous transverse and longitudinal fissures or cracks, the presence and arrangement of which constitute the chief characteristic of Calisaya. Upon the young stems and branches they do not appear. The first to appear are the usually large primary fissures, which encircle the stem at the nodes, or points where pairs of leaves once stood. Subsequently, numerous smaller secondary transverse fissures appear upon the internodes, and these quickly become connected and crossed by longitudinal cracks, thus dividing the periderm up into more or less quadrangular checks, which may remain attached or fall away. This gives to mature Calisaya bark an appearance of scaliness like that upon the tarsus of a fowl, and this is known to the South American collectors by a term which signifies the "chicken-leg appearance." It has also been spoken of as a "carving-like" marking. Like the roughness upon a musk-melon, its great development is regarded as an indication of high quality, and especially is this true of a close proximity of the primary fissures. This roughness is also regarded as a sure indication of maturity. There are excellent distinctions between these and the somewhat similar fissures upon the bark of *C. officinalis*. In the latter they are coarser and more gaping. Even more important is the absence from Pale Bark of most of the longitudinal cracks, so that it does not become "chicken-legged," or at most only very slightly so. The external color of Yellow Bark is lighter than that of the Pale Bark. Longitudinal ridges are few if any, short, irregular, and inconspicuous. In fine South American bark some very small bright-red spots can be detected upon the periderm. East Indian Calisaya can commonly be recognized by its somewhat dingy or brownish shade of gray, the gray of the South American bark being bright and somewhat bluish-steel-colored.

In structure, the zone of large, rather numerous laticiferous ducts just outside the bast is conspicuous in young, and therefore inferior, samples. The rather small bast fibers are loosely scattered, almost uniformly single or a radial arrangement being apparent. The fracture is rough-splintery, though not coarse. Stone cells few or none. Odorless, more bitter, and less astringent than the Pale Bark. Ledger bark is the same as Calisaya in all its essential characters, but does not reach so great a size. In hybrids of Calisaya with succirubra the characters and quality of the latter appear to predominate.

This bark is scarcely collected in a wild state, but cultivated in all plantations. It is the largest quinine yielder, its amount being 70 to 80 per cent. of the total alkaloids contained in the bark. The var. *Ledgeriana* yields a very valuable hybrid bark with *C. succirubra*. *C. Calisaya* also hybridizes with the latter species. Hartwich describes the microscopical characteristics of Cinchona and related barks in *S. W. P.*, 1909, p. 249. Grutterink discusses the microchemistry of Cinchona alkaloids, with illustrations in *Zeit. anal. Chem.*, 1912, p. 215. Rosenthaler reviews the pyro-analytical results that have been obtained with Cinchona bark and describes the crystals found in the tar. (*B. P. G.*, 1911, p. 203.)

Red Bark. Cinchona Rubra.

This bark is recognized by the U. S. and Br. Pharmacopœias (for definition, see page 333). It is described in the U. S. P. IX as "in quills or curved pieces of variable length, bark from 2 to 4 mm. in thickness, or in small broken fragments or in transversely curved pieces from 3 to 7 mm. in thickness; externally gray, grayish-brown, or reddish-brown, more or less rough from corky protuberances, occasionally with transverse fissures which are rarely numerous or much intersected, and having their sides sloping, and with occasional patches of foliaceous lichens; inner surface reddish or orange-brown, distinctly striate; fracture short and granular in the outer bark, shortly and rather coarsely splintery in the inner bark; odor slight; taste very bitter and astringent. The powder is light brown; bast-fibers and sphenoidal micro-crystals of calcium oxalate, resembling those in cinchona; starch grains resembling those of cinchona relatively few, from 0.003 to 0.01 mm. in diameter. Heat 1 Gm. of powdered Red Cinchona in a dry test tube; a tarry distillate forms having a bright red color." *U. S.*

In the British Pharmacopœia it is described as "In quilled or curved pieces, length varying from 5 to 30 cm. or more; usually from about 2.5 to 6 mm. thick; cork brownish or reddish-brown, with longitudinal ridges which are most apparent in the branch bark, and sometimes with reddish warts; inner surface brick-red or deep reddish-brown, irregularly and coarsely striated; fracture shortly fibrous in the smaller, and finely fibrous in the larger, pieces. In transverse section in the cortex, cells filled with minute crystals of calcium oxalate, and also large secretion tubes; in the bast numerous, large, strongly-thickened fibers usually 0.050 to 0.070 mm. wide and about 1 mm. long, isolated or in small groups. The powdered Bark is brownish or reddish-brown, exhibits abundant parenchymatous tissue with brownish cell-walls, and often with brownish contents, small starch grains, and large isolated bast fibers about 0.060 mm. in diameter, with distinctly striated walls. No marked odor; taste bitter and somewhat astringent."

The quills are similar to those of Calisaya, though running somewhat broader and thicker. Externally of a dingy brown gray, less lichen-bearing than either of the others. Inner surface of a more reddish cinnamon-brown than in Calisaya. Powder reddish-brown.

The important characteristic of red bark is the prominent longitudinal ridges, many of them short and confluent, with intervening furrows or elongated meshes. The ridges are suberous, bear numerous small warty protuberances, and may be traversed by faint fissures. Transverse fissures may or may not be present in red bark. If so, they are few, short, and irregularly disposed, and not connected by longitudinal cracks to give the checkered appearance of Calisaya. Hybrids with "officinalis" display numerous transverse fissures, and the external color is lighter and more dingy. Fracture short-splintery, not coarse. Odor none. Taste bitter and astringent.

It is scarcely collected in a wild state, but cultivated in all plantations except those of South America. Demand and production rapidly decreasing. A large alkaloid yielder, but of this only about 20 per cent. is quinine. Largely hybridized with *C. officinalis*. Also hybridized with *C. Calisaya* and its var. *Ledgeriana*.

Pale Bark.

Varieties and Synonyms.—Crown Bark, Loxa or Loja Bark, Cuenca Bark, Huanuco Bark. Derived from *C. officinalis*. Collected in a wild state above Loxa and other parts of Ecuador, and cultivated in all plantations except the South American, especially in India. Demand and production decreasing. Quinine constitutes 60 to 70 per cent. of the total alkaloids. Largely hybridized with *C. succirubra*.

Description.—Quills single or double, irregularly broken or entire, attaining a length of nearly 2 dm., a width of nearly 2.5 cm., and having a very wide range in thickness, the natural mostly 2 to 4 mm. thick. Shaggy, with more abundant lichens than in any other species, the abundance of these having been considered, not entirely without reason, as an indication of the relative quality. Color of periderm darker than in the other species, but varying much from a brown gray to nearly black. Inner surface of a paler brown than in the other species, finely striate. Color of powder pale brown. The external markings consist of transverse fissures and longitudinal ridges, some of them wart-bearing. It is only in the thinner samples, in which the warts and fissures scarcely appear, that the ridges are continuous and conspicuous. In the prominence and breadth of its fissures and the inconspicuousness of its ridges, this bark is most distinct from the Red Bark. These characters are yet sufficiently distinct from the somewhat similar ones of Calisaya, as noted in describing that bark.

Fracture short, the inner fibrous zone sharp and narrow. Taste not so bitter as in the others. Odor of the genuine Loxa variety peculiar and characteristic. Its structure shows the rather short and not numerous bast fibers in short interrupted single or double radial rows, and much disposed to occur in bundles of three to six or more. Stone cells rarely seen, and laticiferous ducts conspicuous only when young.

Hard Yellow, or Maracaibo Bark. Puerto Cabello Bark.

Derivation not at all certain. Collected only in a wild state in the mountains of Southern Colombia, and yielding almost the whole of the inferior wild bark now collected for market. Importation and sale in the United States quite irregular and unimportant. One of the best of the lower-grade barks, but not to be compared with any of those already described. Said to yield about 2 per cent. of crystallizable sulphates, three-fourths of which is quinine sulphate, but a characteristic specimen assayed for this investigation by Virgil Coblentz yielded 2.65 per cent. of total alkaloids, only a trace of which was quinine. Contains a large amount of resin. The common or commercial names by which have been designated the several barks of the northern countries related to this one are of very irregular application. At the time when the trade in them was large and important, the term "Maracaibo Bark" was restricted to the less resinous variety, derived from *C. cordifolia*. It was also formerly sold simply as "Yellow Bark," and it is not impossible that it was sometimes accepted, under this synonym, for Calisaya. The investigations of Morgenthau into the value of certain derivatives of cuprein may give these barks a real value. For a description of *Cuprea Bark*, see 19th ed., *U. S. D.*, p. 349.

Description.—Rusby described it as occurring in irregular broken pieces, mostly from 5 to 15 cm. long, 2.5 to 7 cm. broad, and 3 to 10 mm. thick. Formerly it included many much smaller fragments as well as much dust, but these portions are now mostly sifted and winnowed out before marketing. The pieces are more or less flat, the thinner and narrower ones somewhat incurved, the broader and thicker recurved. The bark is compact, heavy, and fibrous. Most of the pieces display upon the outer surface more or less of the periderm, forming silvery-white or yellowish-white patches, very thin and rather soft. Occasionally the periderm is instead dark, hard, very rough, and much fissured. From many pieces the entire periderm is absent, disclosing the outer face of the bast, very similar to the inner face. This is compactly and rather finely fibrous, of a deep yellow, with a slight rust-brown tinge. Throughout, the bast is of this structure and color. Between it and the periderm there may be seen with varying distinctness, in most pieces, a characteristic resinous band of irregular width, dark reddish-brown and waxy-lustrous on the cut surface. The radial rows of bast fibres are irregular. The fracture is long-fibrous. The odor is distinct, and the taste quite bitter.

Chemical History.

In the analysis of Cinchona bark, the attention of chemists was at first directed exclusively to the action of water and alcohol upon it, and to the determination of the relative proportions of its gummy or extractive and resinous matter.

The presence of tannin and of various alkaline or earthy salts in minute quantities was afterwards demonstrated. Fourcroy made an elaborate analysis, which proved the existence of other principles in the bark besides those previously ascertained. Westring was the first who attempted the discovery of an active principle in the bark, on which its febrifuge virtues might depend; but he was not successful. Seguin afterwards pursued the same track, and endeavored, by observing the effects of various reagents, to discover the relative value of different varieties of the drug; but his conclusions were not supported by subsequent experiment. Deschamps, an apothecary of Lyons, obtained from the bark a crystallizable salt of lime, the acid of which Vauquelin afterwards separated, and called *kinic acid* (*quinic acid*). The latter chemist also pushed to a much greater extent the researches of Seguin as to the influence of reagents, and arrived at the conclusion that those barks were most efficient which gave precipitates with tannin or the infusion of galls. Ruess, of Moscow, succeeded in isolating a peculiar coloring matter from red bark, which he designated by the name of *cinchonic red,* and obtained a bitter substance which probably consisted in part of the peculiar alkaline principles subsequently discovered. The first step, however, towards the discovery of cinchonine and quinine appears to have been taken by Duncan of Edinburgh, so early as 1803. He believed the precipitate afforded by the infusion of cinchona with that of galls to be a peculiar vegetable principle, and accordingly denominated it *cinchonin.* Gomez, a Portuguese physician, convinced that the active principle of bark resided in this cinchonin, but mixed with impurities, instituted experiments upon some pale bark, which resulted in the separation of a white crystalline substance, considered by him to be the pure *cinchonin* of Duncan. It was obtained by the action of potassium hydroxide upon an aqueous infusion of the alcoholic extract of the bark, and was undoubtedly the principle now universally known by the name of *cinchonine* or *cinchonia.* But Gomez was ignorant of its precise nature, considering it to be analogous to resin. Laubert afterwards obtained the same principle by a different process, and described it under the name of *white matter,* or *pure white resin.* To Pelletier and Caventou was reserved the honor of crowning all these experiments, and applying the results which they obtained to important practical purposes. In 1820 they demonstrated the alkaline character of the principle discovered by Gomez and Laubert, and gave it definitively the name of *cinchonine.* They discovered in the yellow or Calisaya bark another alkaline principle, which they denominated *quinine.* Both these bases they proved to exist in the bark, combined with *quinic* or *kinic acid.* It was, moreover, established by their labors that the febrifuge property of bark depends upon the presence of these two principles. In 1833, O. Henry and Delondre discovered a new alkaloid, but afterwards, finding its composition in its anhydrous state the same as that of quinine, concluded that it was a hydrate of that base. About 1844, Winckler announced anew the existence of the same principle, which he considered distinct, and named *chinidine,* and, under the similar title of *quinidine,* it has now taken its place among the cinchona alkaloids. In 1853, Pasteur found that what had been considered as quinidine consisted in fact of two alkaloids, for one of which he retained the name of quinidine, and called the other *cinchonidine,* and, on pushing his investigations further, he ascertained that no less than six alkaloids may be obtained from different varieties of Peruvian bark,—namely, *quinine* and *quinidine* isomeric with each other, *cinchonine* and *cinchonidine* also isomeric, and two others, derivatives from the preceding through the agency of heat, viz., *quinicine* from quinine, and *cinchonicine* from cinchonine, each being isomeric with the alkaloid from which it is derived.

The table (page 344) of the natural Cinchona bases is given by A. H. Allen on the authority of Paul and Cownley. In it the alkaloids are arranged according to formulas.

Besides these natural bases we have a number of alkaloids formed by the alteration or treatment of these natural bases, or in some cases molecular compounds of two of the natural bases. They will be noted later in the description of individual bases.

Chinoidine or *Quinoidine* is a term now applied to the resinous substance consisting not only of the *amorphous* natural alkaloids, but of those which are produced artificially through the action of the heat and acids upon the crystalline alkaloids. It was formerly official, but was dropped at the 1890 revision. The following list of bases from Cinchona or allied sources is arranged alphabetically.

APOQUINAMINE. See *Homocinchonine.*

ARICINE, $C_{23}H_{26}N_2O_4$. *Cinchovatine.*—This alkaloid, found in cusco bark and in Cuprea bark, was formerly believed by Hesse to be identical with cinchonidine. Pelletier and Corriol obtained *aricine* as far back as 1829 (see note, p. 308, 14th ed., *U. S. D.*). Its separate existence is now not doubted. It crystallizes in prisms, and its salts are of sparing solubility.

CHAIRAMIDINE, $C_{22}H_{26}N_2O_4 + H_2O$, is an alkaloid obtained from *Remijia Purdieana.*

CHAIRAMINE, $C_{22}H_{26}O_4N_2$, discovered by Hesse in *Remijia Purdieana,* occurs in white needles which are readily soluble in ether and chloroform. (*Ann. Ch. Ph.*, ccxxv, p. 211.)

CINCHAMIDINE, $C_{19}H_{24}ON_2$, is identical with hydrocinchonidine.

CINCHONAMINE, $C_{19}H_{24}ON_2$.—This alkaloid was discovered in 1881 by Arnaud in *Remijia Purdieana* (false cuprea bark). It exists in the proportion of 0.2 per cent., and is usually associated with cinchonine. His process is to treat the bark with milk of lime, dry the mixture, exhaust with boiling alcohol, distil off the

alcohol, and take up the residue with diluted hydrochloric acid; cinchonamine hydrochloride crystallizes out, cinchonine hydrochloride remaining in solution. Cinchonamine is insoluble in cold water, soluble in thirty parts of alcohol, more soluble in hot alcohol, and in 100 parts of ether. It is dextrogyrate. For formulas for salts of cinchonamine, see *A. J. P.*, 1884, 156. Physiologically, cinchonamine, according to the experiments of Sée and Bochefontaine, has six times the toxic power of quinine, and has decided sialagogue properties. (*P. J.*, 1885, 791.)

CINCHONICINE, $C_{19}H_{22}ONa$, being a derivative of cinchonine, will be treated elsewhere. (See Index.)

CINCHONIDINE, $C_{19}H_{22}ONa$.—This alkaloid is treated under the head of its sulphate, which is official in both the U. S. and Br. Pharmacopœias.

CINCHONINE, $C_{19}H_{22}ONa$, was dismissed from the U. S. (8th Rev.) but its sulphate has been retained and a description of it will be found on page 353.

CINCHOTINE, $C_{19}H_{24}ONa$, is isomeric with cinchonamine and hydrocinchonine; it dissolves very sparingly in ether.

CONCHAIRAMIDINE, $C_{22}H_{26}O_4N_2 + H_2O$, crystallizes in white needles, and is very soluble in ether, chloroform, alcohol, benzene and acetone. (*Ann. Ch. Ph.*, CCXXV, p. 211.)

CONCHAIRAMINE, $C_{22}H_{26}O_4N_2 + H_2O + C_3H_8O$, also discovered by Hesse, crystallizes with both water and alcohol of crystallization. It is soluble in hot alcohol, ether, and chloroform. The alcoholate dissolves in sulphuric acid containing molybdic acid, giving a brown coloration, which soon becomes intensely green. (*Ann. Ch. Ph.*, CCXXV, p. 211.)

CONCUSCONINE, $C_{23}H_{26}O_4N_2$, discovered by Hesse, occurs in the barks of *Remijia*. It is tasteless.

CONQUINAMINE, $C_{19}H_{24}O_2N_2$, occurs with quinamine. According to Allen, it is easily soluble in ether, chloroform and benzene and closely resembles quinamine.

CUPREINE, $C_{19}H_{22}O_2N_2$, was discovered by Paul and Cownley in the bark of *Cinchona cuprea*, or *Remijia pedunculata*, on the upper

Alkaloid.	Formula.	Melting Point, °C.	Optical Rotation, SD.[1]	Chief Source.
I. *Cinchonine Class:*				
Paricine	$C_{16}H_{18}N_2O$	130	0	*C. lutea* and *C. succirubra* from Darjeeling.
Cinchotine	$C_{19}H_{24}N_2O$	277	+	Crude cinchonine sulphate
Cinchonamine		194	+121.1	*Remijia Purdieana.*
Hydrocinchonine		256	. .	*C. cuprea.*
Hydrocinchonidine, (Cinchamidine)		. . . 229	—98.4	Mother liquors of homocinchonidine.
Cinchonine	$C_{19}H_{22}N_2O$	255	+226.5	Various species of *cinchona.* Almost always present.
Cinchonidine		202	—70	Especially *C. rubra.*
Homocinchonidine		207	—107	With cinchonidine.
Cinchonicine		50	+20.1	By heating cinchonine.
Paytine	$C_{21}H_{24}N_2O$	156	—49.5	From white bark of Payta.
Paytamine		. .	. .	
II. *Quinamine Class:*				
Quinamine	$C_{19}H_{24}N_2O_2$	172	+104.5	*C. succirubra* from British India and Java.
Conquinamine		121	+204.6	*C. officinalis, C. Calisaya.*
Javanine		. . .	. .	*C. Calisaya* from Java.
Cupreine	$C_{19}H_{22}N_2O_2$	198	—175.3	*C. cuprea* or *Remijia pedunculata.*
III. *Quinine Class:*				
Hydroquinine	$C_{20}H_{26}N_2O_2$	168	—142.2	In mother liquors from quinine sulphate.
Hydroquinidine		166	+	
Quinine	$C_{20}H_{24}N_2O_2$	172	—145.2	*Calisaya officinalis*, etc.
Quinidine		168	+236.8	
Quinicine		60	+44	By heating quinine sulphate.
IV. *Cusconine Class:*				
Chairamine	$C_{22}H_{26}N_2O_4$	233	+100	*Remijia Purdieana* (Cusco or False Cuprea Bark).
Conchairamine		120	+68.4	
Chairamidine		127	+7.3	
Conchairamidine		114	—60	
Concusconine		144	+40.8	
Aricine	$C_{23}H_{26}N_2O_4$	188	—58.2	
Cusconine		110	—54.3	
Cusconidine	$C_{23}H_{28}N_2O_4$	. .	. .	
Cuscamine	. . . . .	218	. .	*C. Pelletierana.*
Cuscamidine		. .	. .	
V. *Anhydro-bases:*				
Dicinchonicine	$C_{38}H_{44}N_4O_2$	40	+66	*C. rosulenta* and *C. succirubra.*
Diquinicine	$C_{40}H_{46}N_4O_2$	. .	+	*C. rosulenta* and "quinoidine."

[1] The values for the specific rotatory power refer to solutions of the free alkaloids in nearly absolute alcohol.

Orinoco. It crystallizes from alcohol in anhydrous form, but from ether in prisms with $2H_2O$. Cupreine is sparingly soluble in ether or chloroform, but readily soluble in alcohol. This solution is lævogyrate, alkaline, gives a dark reddish-brown color with ferric chloride, and responds to the thalleioquin test. It forms with sodium hydroxide a definite crystallizable compound, $C_{19}H_{21}N_2O.ONa$, from the solution of which the alkaloid cannot be extracted by ether. This cupreine-soda is important as furnishing a synthesis of quinine, according to the reaction:

$$C_{19}H_{21}N_2O.ONa + CH_3I = C_{20}H_{24}N_2O_2 + NaI$$

(See *Optochin*, Part II.)

CUSCAMIDINE, obtained from *C. Pelletierana.*

CUSCAMINE, obtained from *C. Pelletierana.*

CUSCONIDINE is an amorphous alkaloid found in cusco bark, accompanying cusconine.

CUSCONINE, $C_{23}H_{26}O_4N_2.2H_2O$.—This was discovered by Leverköhn. It is a constituent of the *cusco bark* (*C. pubescens* var. *Pelletierana*), and Hesse has found it in Cuprea bark. It is nearly insoluble in water, soluble in thirty-five parts of ether, more easily in alcohol, very soluble in chloroform. It may be distinguished from other cinchona alkaloids by forming with sulphuric acid a neutral sulphate, which is amorphous, gelatinous, and yellow, and insoluble in an excess of the acid.

DICINCHONICINE, $C_{38}H_{44}O_2N_4$, *dichonchinine* or *apodicinchonine*, is prepared from cinchonine and cinchonidine, and found in commercial chinoidine. It probably exists in bark in an amorphous condition.

DICINCHONINE, $C_{38}H_{44}O_2N_4$, exists in the bark of *C. rosulenta* and *C. succirubra*, and may also be obtained by fractional precipitation from the mixed amorphous alkaloids before melting, but not from commercial chinoidine.

DIHOMOCINCHONINE, $C_{38}H_{44}O_2N_4$, is an amorphous alkaloid obtained from *C. rosulenta*. It is dextrogyrate.

DIQUINICINE, $C_{40}H_{46}O_3N_4$, also termed *disconchinine* and *apodiquinidine*, is one of the chief amorphous alkaloids in commercial chinoidine; its formula indicates its relation to quinine or quinidine. By deducting one molecule of water from a double molecule of either there results diquinicine, thus:

$$2C_{20}H_{24}O_2N_2 - H_2O = C_{40}H_{46}N_4O_3$$

DIQUINIDINE, *dichonchinine* of Hesse, $C_{40}H_{46}N_4O_3$, is found principally in chinoidine which has been obtained from barks containing quinine and quinidine. It is dextrogyrate, produces a fluorescent solution with diluted sulphuric acid, and responds to the thalleioquin reaction.

HOMOCINCHONICINE is prepared from homocinchonidine just as cinchonicine and quinicine are prepared from cinchonine and quinine—*i.e.*, by heating their sulphates.

HOMOCINCHONIDINE, $C_{19}H_{22}ON_2$, is also obtained from *C. rosulenta*. It crystallizes in large prisms, and forms a neutral sulphate containing six molecules of water, and may be found in commerce. Its existence is denied by Skraup.

HOMOCINCHONINE, $C_{19}H_{22}ON_2$, *cinchonidine of Koch*, is obtained from the bark of *C. rosulenta;* it is lævogyrate, and crystallizes from its alcoholic solution in large prisms. It has been mistaken for *aricine*. Homocinchonine is isomeric with *apoquinamine*, which is prepared by boiling quinamine or quinamidine with hydrochloric acid for a short time. It is white, amorphous, soluble in ether, alcohol, and diluted hydrochloric acid.

HOMOQUININE, $C_{39}H_{46}O_4N_4 + 4H_2O$, was discovered in 1881 simultaneously by D. Howard and J. Hodgkin, B. H. Paul, A. J. Cownley, and T. G. Whiffen (*P. J.*, 1881, p. 497; 1882, p. 905.) It was first noticed by Paul and Cownley on account of the readiness with which it crystallized from its ethereal solution, and is now recognized as a molecular compound of quinine and cupreine of the formula $C_{20}H_{24}O_2N_2.C_{19}H_{22}O_2N_2 + 4H_2O$, and can be obtained by precipitating a solution of sodium cupreinate with one of quinine hydrochloride. It can be resolved into its constituent parts by precipitating the solution with solution of sodium hydroxide, when the quinine may be shaken out with ether, while the cupreine remains in the alkaline liquid as sodium cupreinate. It is freely soluble in alcohol and chloroform, sparingly in ether, from which it crystallizes in proportion as it can take up water. (Hesse.) It is also soluble in diluted sulphuric acid, producing fluorescence, and gives with chlorine water and ammonia a green coloration (thalleioquin). The sulphate coincides exactly in properties with quinine sulphate, except in its behavior with ether. Its tartrate closely resembles cinchonidine tartrate. Homoquinine and its salts behave towards polarized light like quinine.

HYDROCINCHONIDINE, $C_{19}H_{24}N_2O$, bears the same relation to cinchonidine that hydroquinine does to quinine. It is found associated with homocinchonidine in commercial cinchonidine. (*A. J. P.*, 1883, p. 20.)

HYDROCINCHONINE, $C_{19}H_{24}ON_2$, discovered by Caventou, is obtained by treating cinchonine with potassium permanganate. It is soluble in 1300 parts of water, more soluble in alcohol and in ether. The statement that it may be found in commercial cinchonine has not been confirmed. Hesse states that it may be found in Cuprea bark. It is also called *cinchotine*. Von Arlt has shown that the *pseudocinchonine* of Hesse is identical with hydrocinchonine.

HYDROQUINICINE, $C_{20}H_{26}O_2N_2$, an amorphous alkaloid obtained by fusing dry hydroquinine sulphate.

HYDROQUINIDINE (*hydroconchinine*), $C_{20}H_{26}O_2N_2 + 2\frac{1}{2}H_2O$, is found in commercial quinidine and may be separated by potassium permanganate treatment. It is crystalline, dissolving freely in hot alcohol and in chloroform, but less freely in ether. It gives the thalleioquin reaction like quinine. (*P. J.*, 1882, p. 904.)

HYDROQUININE, $C_{20}H_{26}O_2N_2$, was discovered by Hesse in the mother liquors from which quinine sulphate has been crystallized; he afterwards found it in the commercial quinine salt to the extent of 4 per cent. Quinine cannot be perfectly freed from hydroquinine even by repeated crystallization of the neutral sulphates, but the hydroquinine can be completely separated by converting the alkaloid into the acid sulphate and recrystallizing this from water or alcohol, when the hydroquinine remains in the mother liquor. (Allen.) According to Hesse, it dissolves freely in alcohol and ether, and, ac-

cording to Allen, also in chloroform, benzene and ammonia water, and gives the thalleioquin reaction with chlorine water and ammonia like quinine. (*P. J.*, 1882, p. 904.)

JAVANINE, obtained by Hesse from *C. Calisaya* var. *javanica.*

PARICINE, $C_{18}H_{18}ON_2$, is found with quinamine in the bark of *C. succirubra* of Darjeeling, and, according to Hesse, it may be separated from all the cinchona alkaloids with which it associates in solution by treating with sodium carbonate, which precipitates paricine first.

PAYTAMINE, $C_{20}H_{24}ON_2$, is an amorphous alkaloid accompanying paytine.

PAYTINE, $C_{21}H_{24}O_2N_2,H_2O$, was discovered by Hesse in the white Payta bark.

PROTOQUINAMICINE (see *Quinamicine*).

QUINAMICINE is isomeric with quinamidine; it with protoquinamicine is an artificial base, they are both amorphous, and are produced by heating quinamine in contact with diluted sulphuric acid. If the action of sulphuric acid be continued at 120° C. (248° F.) to 130° C. (266° F.), an amorophous brownish substance is formed which may be precipitated by sodium carbonate, and is insoluble in ether. Hesse has named this protoquinamicine.

QUINAMIDINE, *Quinidamia* (*Conchinamine of Hesse*), $C_{19}H_{24}O_2N_2$, is found in *C. rosulenta* and *C. succirubra,* and probably exists in other species of red bark. It crystallizes in long, brilliant prisms, which melt at 123° C. (253.4° F.). A crystalline hydriodide has been produced. Its gold salt like that of quinamine soon decomposes. It may be formed in acid solutions of quinamine through decomposition.

QUINAMINE, *Quinamia,* $C_{19}H_{24}O_2N_2$.—Hesse discovered this cinchona alkaloid in the bark of *C. succirubra* from Darjeeling in 1872. He has since found it in all the East Indian succirubra barks, as well as in the barks of *C. nitida, C. Calisaya,* var. *Schuhkraffti, C. erythrantha, C. erythroderma, C. rosulenta,* and *C. Calisaya* (Para bark), and particularly in *C. Ledgeriana.* De Vrij (*L'Union Pharm.*, 1877, p. 204; *N. R.*, 1877, p. 300) published a process for its preparation. It crystallizes in very long, asbestos-like, white prisms, without water of crystallization. It is nearly insoluble in cold water and in solution of potassium or ammonium hydroxides, more easily in boiling water; is readily dissolved by hot alcohol, which deposits it in crystals, and less readily by diluted alcohol. Ether, petroleum benzin, and benzene dissolve it rather easily at ordinary temperature, more readily when boiling hot, and give it up crystallized on cooling and evaporation. In alcoholic solution it has an alkaline reaction. It neutralizes sulphuric and hydrochloric acids, forming with the latter an amorphous salt, but with the former one that crystallizes with difficulty in hexagonal scales and short prisms. Its solution is dextrogyrate. Quinamine is almost tasteless, but its solutions in acids are very bitter. Its sulphuric acid solution unlike that of quinine is not fluorescent. Its reaction with gold chloride is very characteristic, the solution of the chloride producing with it a yellowish-white precipitate, which soon becomes purple, and separates gold, the supernatant liquid assuming a purplish-red and afterwards a brown color. (For other characters, see *A. J. P.*, 1872, p. 302.)

QUINIDINE, $C_{20}H_{24}O_2N_2$, is isomeric with quinine. It was discovered in 1833 by O. Henry and Delondre, but they afterwards concluded that it was quinine hydroxide, as it had the same composition as quinine. Winckler, in 1844, announced anew the existence of the same alkaloid, which he considered distinct, and named it "*chinidine*"; this substance was not pure, and Pasteur, in 1853, proved that it really consisted of two alkaloids, one of which he called *cinchonidine,* and the other *quinidine.* This view is now generally accepted, although Hesse insists on calling quinidine "*conchinine*"; but the latter name is used to only a limited extent in Germany, and scarcely at all elsewhere.

Quinidine crystallizes from alcohol with $2\frac{1}{2}H_2O$ in large lustrous monoclinic prisms or needles, efflorescent in the air; from ether, permanent rhombohedra with $2H_2O$ are obtained; from boiling water permanent plates with $1\frac{1}{2}H_2O$. (Hesse.) It effloresces on exposure to the air. It is sublimable by heat without change, and is condensed in a crystalline form. It resembles quinine not only in composition, but also in its chemical relations with chlorine and ammonia, being rendered green by the successive action of those agents. According to Herapath, it resembles it also in causing a fluorescent appearance when dissolved in water, which is not the case with either cinchonine or cinchonidine, or is so, at least, in a much less degree. It differs, however, in its greater facility of crystallization, in its much less solubility in ether, and in its influence on polarized light, quinidine producing deviation to the right, and quinine to the left. De Vrij states, as the result of his observation, that quinidine forms a salt of very difficult solubility with hydriodic acid, and that, consequently, when a solution of potassium iodide is added to a solution of quinidine sulphate a white precipitate is deposited. By this test quinidine may be distinguished from the other cinchona alkaloids, and detected when mixed with them in solution, no other yielding a precipitate with potassium iodide. (See *A. J. P.*, xxix, 233.) Herapath proposes another test to distinguish this alkaloid from quinine. If to a solution of quinine sulphate in acetic acid, tincture of iodine be added, and the mixture heated and then allowed to cool, a beautiful emerald-green compound is formed, while quinidine sulphate treated in the same way yields a brown precipitate. When the mixture of this alkaloid with cinchonidine is exposed to hot air, the crystals of quinidine effloresce, and may be distinguished from the others by their opaque whiteness. Vreven (*C. D.*, March 5, 1898, 400) states that

the crystals yielded by Marmé's reagent (potassio-cadmium iodide) with quinidine are different from those obtained from any of the other cinchona alkaloids. They are seen under the microscope to consist of bundles of fine needle-like crystals quite different from those of quinine, cinchonine, and cinchonidine.

Commercial quinidine, consisting generally of quinidine with a much larger proportion of cinchonidine, and sometimes, there is reason to believe, exclusively, or nearly so, of the latter alkaloid, was carefully examined by H. G. Leers. It readily crystallizes from its alcoholic solution, by spontaneous evaporation, in hard, shining, colorless crystals, which are easily pulverized and yield a snow-white powder. They melt without decomposition or loss of water at 175° C. (347° F.), and on cooling concrete into a grayish-white crystalline mass. At a higher heat they take fire, and burn with an odor resembling that of the volatile oil of bitter almond. Their taste is bitter, but less intensely so than that of quinine. Quinidine is soluble, according to Hesse, in 2000 parts of water at 15° C. (59° F.); in 750 parts of boiling water; in 26 parts of 80 per cent. alcohol at 20° C. (68° F.); in 22 parts of ether of sp. gr. 0.729 at 20° C. (68° F.), or in 35 parts of the same at 10° C. (50° F.) (Hesse, 1868); according to Dragendorff, in 76.4 parts of ether at 10° C. (50° F.); but the solubilities of commercial quinidine vary more or less according to the relative quantities of quinidine proper and cinchonidine contained in it. With the acids it forms salts, most of which are beautifully crystallizable, and much more soluble than those of quinine. There are, as of quinine and cinchonine, two classes of the salts of quinidine, which may be considered either as neutral and acid or as basic and neutral. It differs from quinine by its much slighter solubility in ether. From the aqueous solution of its salts the alkalies and their carbonates and bicarbonates throw down pulverulent precipitates not soluble in an excess of the precipitant. With sodium phosphate, silver nitrate, and mercuric chloride it forms white, with gold trichloride light yellow, and with platinic, orange-yellow precipitates. It may be obtained by first precipitating it from the solution of one of its salts by an alkali, and then repeatedly dissolving in alcohol and crystallizing, until it is entirely freed from a greenish-yellow resinous substance which is apt to attend it. From quinine it may be separated by repeated washing with ether.

The sulphate of this alkaloid was official in the U. S. P. 1890, and described as follows:

QUINIDINÆ SULPHAS. U. S. 1890, *Quinidine Sulphate.* $(C_{20}H_{24}N_2O_2)_2H_2SO_4.2H_2O = 780.42$.

"The neutral sulphate of an alkaloid obtained from the bark of several species of Cinchona (fam. *Rubiaceæ*). Quinidine Sulphate should be kept in well-stoppered bottles, in a dark place." *U. S.* 1890.

Quinidine sulphate is obtained from the quinidine barks by the same process as that by which quinine sulphate is procured from the quinine-yielding barks. When the two alkaloids are contained in the same bark, the quinidine sulphate (commercial) remains in the mother waters in consequence of its greater solubility. By the addition to its solution of a quantity of sulphuric acid equal to that which it already contains, it is converted into fine acicular crystals like asbestos, and possessing the formula $C_{20}H_{24}N_2O_2H_2SO_4 + 4H_2O$. Quinidine sulphate was officially described as in "white, silky needles, odorless, and having a very bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 100 parts of water, and in 8 parts of alcohol; in 7 parts of boiling water, and very soluble in boiling alcohol; also in 14 parts of chloroform, and in acidulated water; almost insoluble in ether. When heated to 120° C. (248° F.), the salt loses its water of crystallization (4.6 per cent.). Upon ignition, it is slowly consumed, leaving no residue. The salt is neutral or faintly alkaline to litmus paper. An aqueous solution of the salt, when acidulated with sulphuric acid, has a decided, blue fluorescence. On treating 10 mils of an aqueous solution (about 1 in 1600) of the salt with 2 drops of bromine water, and then with an excess of ammonia water, the liquid will acquire an emerald-green color. With proper adjustment of the reagents, more dilute solutions will give a paler tint, while more concentrated ones will acquire a deeper color, or deposit a green precipitate. A cold, saturated aqueous solution of the salt yields a white precipitate with potassium iodide test-solution (difference from *quinine sulphate*). An aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate insoluble in hydrochloric acid. Quinidine Sulphate should not impart more than a faintly yellowish tint to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*), nor produce a red color with nitric acid (difference from *morphine*). If a small quantity of ammonia water be added to 3 mils of an aqueous solution of the salt saturated at 15° C. (59° F.), a white precipitate (quinidine) will be produced, which requires more than 30 mils of ammonia or more than 30 times its weight of ether to dissolve it (absence of more than small proportions of *other cinchona alkaloids*)." *U. S.* 1890.

The action of quinidine sulphate upon the system is similar to that of quinine, but is less powerful in the proportion of three to two.

QUINICINE, $C_{20}H_{24}O_2N_2$, being a derivative of quinine, will be treated under that head.

QUININE, $C_{20}H_{24}O_2N_2 + 3H_2O$.—This alkaloid has been made official, as have its sulphate, bisulphate, hydrobromide, hydrochloride, salicylate, and sulphate, and they will be treated under separate heads. (See Index.)

The following additional substances have been found in Cinchona bark: *Quinic* or *Kinic*, *Quinovic* or *Kinovic*, *Quinotannic* or *Cinchotannic acids*, *Quinovin* or *Kinovin*, *Cinchonic red*, volatile butyraceous oil, in small quantity,

and red and yellow coloring matter. These constituents, arranged alphabetically, will now be considered in detail.

CINCHOCEROTIN, $C_{27}H_{48}O_2$.—This substance was discovered by Kerner in flat Calisaya bark from South America. He obtained it in white, very light, crystalline scales. It is not soluble in boiling water, nor in hydrochloric, diluted sulphuric, or glacial acetic acid, but dissolves readily in ether, chloroform, and alcohol. (*A. J. P.*, 1883, p. 357.)

CINCHOFULVIC ACID.—The *cinchonic red* of Reuss, identical with the *insoluble red coloring matter* of Pelletier and Caventou, $C_{12}H_{14}O_7$, is reddish brown, insipid, inodorous, largely soluble in alcohol, especially when hot, and almost insoluble in ether or water, though the latter dissolves a little at the boiling temperature. The acids promote its solubility in water. It precipitates tartar emetic, but not gelatin; but if treated with a cold solution of potassium or sodium hydroxide, or with ammonia, lime, or baryta with heat, and then precipitated by an acid, it acquires the property of forming an insoluble compound with gelatin. It yields protocatechuic acid, $C_7H_6O_4$, when fused with potassium hydroxide. It is most abundant in the red bark (over 10 per cent.), and least so in the pale.

CINCHOTANNIC ACID. *Cinchotannin*, $C_{14}H_{16}O_9$.—*Tannic acid, tannin*, or *soluble red coloring matter* of Pelletier and Caventou, has been considered as possessing all the properties which characterize the proximate vegetable principles associated together under the name cinchotannic acid. It is a glucoside existing in cinchona barks in the proportion of 3 to 4 per cent. It has a brownish-red color and an austere taste, is soluble in water and alcohol, combines with metallic oxides, and produces precipitates with the salts of iron, which vary in color according to the variety of bark, being deep green with the pale bark, blackish-brown with the yellow, and reddish-brown with the red. It also forms white precipitates with tartar emetic and gelatin, and readily combines with atmospheric oxygen, becoming insoluble. It must, however, differ materially from the tannic acid of galls, which could not exist in aqueous solutions containing cinchonine and quinine without forming insoluble compounds with them. Rembold has shown that when cinchotannic acid is boiled with diluted sulphuric acid, cinchonic red is produced, sugar being formed at the same time.

FATTY MATTER.—This was first obtained pure by Laubert, and is of a greenish color as obtained from the pale bark, orange yellow from the yellow. It is insoluble in water, soluble in boiling alcohol, which deposits a part of it on cooling, very soluble in ether, even cold, and saponifiable with the alkalies.

QUINIC ACID (*Hexahydrotetraoxybenzoic acid*), $C_7H_{12}O_6$.—This acid was isolated as early as 1790 by Hofmann, an apothecary of Leer, who obtained it from the calcium salt from cinchona. It exists in a number of important plants—ivy, oak, elm, ash, coffee, etc. It may be desirable to procure the alkaloids in the state of saline combination in which they exist in the bark, since it is possible that they may exert an influence over the system in this state somewhat different from that produced by their combinations with sulphuric or other mineral acids. As it is impossible to procure the quinates immediately from the bark in a pure state, it becomes necessary first to obtain the quinic acid separately, which may thus become of some practical importance. We shall, therefore, briefly describe the mode of procuring it, and its characteristic properties. It is usually prepared from calcium quinate, the residue obtained in the manufacture of quinine sulphate (see *Quininæ Sulphas*) by decomposing an aqueous solution of calcium quinate with oxalic acid, filtering out the precipitated calcium oxalate, and evaporating the filtrate to the crystallizing point; or by evaporating the infusion of bark to a solid consistence, and treating the extract with alcohol, we have in the residue a viscid matter consisting chiefly of mucilage with calcium quinate, which is insoluble in alcohol. If an aqueous solution of this substance be formed, and allowed to evaporate at a gentle heat, crystals of the quinate will be deposited, which may be purified by a second crystallization. The salt thus obtained, being dissolved in water, is decomposed by means of oxalic acid, which precipitates the lime and leaves the *quinic acid* in solution. This may be procured in the crystalline state by spontaneous evaporation, though as usually prepared it is in the form of a thick syrupy liquid. The crystals are transparent and colorless, sour to the taste, soluble in 2 parts of water, but less soluble in alcohol, and almost insoluble in ether. By heating quinic acid or a quinate with manganese dioxide and sulphuric acid, we get yellow crystals of *kinone*, better known as *quinone*, $C_6H_4O_2$, a reaction which may be used for ascertaining the presence of quinic acid. The cinchonine and quinine quinates may be obtained either by the direct combination of their constituents, or by the mutual decomposition of the sulphates of those alkaloids and calcium quinate. *Cinchonine quinate* has a bitter and astringent taste, is very soluble in water, is soluble also in alcohol, and is crystallized with difficulty. *Quinine quinate* is also very soluble in water, but less so in rectified alcohol. Its taste is very bitter, resembling that of yellow bark. It crystallizes in beautiful stellate groups, which are opaque or semi-transparent. The salt is with difficulty obtained free from color, and only by employing the ingredients in a state of extreme purity. (*Ann. Ch. Phys.*, Juillet, 1829.) Lautemann found, in experiments upon himself, that quinic acid, when taken into the system, undergoes a conversion into hippuric acid and in this state escapes with the urine. (*Ann. Ch. Ph.*, cxxv, 9.) Rabuteau has investigated the physiological properties of quinic acid, and has found it closely to resemble the

ordinary vegetable acids, being harmless in its effects on the system, and forming with water a refreshing drink like lemonade. Like other vegetable acids, also, it is decomposed in the system, forming, when taken in the state of an alkaline salt, a carbonate of the alkali in the blood, and rendering that fluid alkaline. (*A. J. M. S.*, Oct., 1872, p. 524.) Quinic acid is said by Zwenger to have been found in the leaves of *Vaccinium Myrtillus* L. (*A. J. P.*, March, 1861, p. 128.) Several esters of quinic acid and compounds with synthetic bases have been introduced into medicine, viz.—*chinotropin, sidonal, new sidonal, urosin,* and *ural.* (See Part II.)

Quinovin, *Kinovin,* or *Chinovin. Kinovic bitter,* $C_{36}H_{62}O_{11}$.—Originally discovered in the false bark called *quinquina nova,* or new bark, this substance has since been found in Calisaya bark, and probably exists, in greater or less proportion, in all the Cinchona barks. It was detected by De Vrij not only in the bark but also in the wood and leaves of *C. Calisaya* and *C. lucumæfolia.* (*J. P. C.*, April, 1860, pp. 225, 258.) It is white, uncrystallizable, almost insoluble in water, but readily dissolved by alcohol and ether. It is very bitter, and, as it is asserted to have no febrifuge virtues, may on this account mislead the judgment in relation to the activity of the bark in which it may be found. Some barks are said to owe their bitterness mainly to this ingredient. Winckler gives, as a certain test of its presence in any bark, copper sulphate, which is indifferent to infusion of bark containing none of this principle, but detects the smallest proportion of it by producing a dirty-green color, soon followed by the deposition of a fine similarly colored powder. This is a salt of copper, and has a very bitter and metallic taste. (See *A. J. P.*, xxv, 343.)

Quinovin in alcoholic solution was shown in 1859 by Hlasiwetz to be resolved by means of hydrochloric acid gas into quinovic acid, $C_{24}H_{38}O_4$, and an uncrystallizable sugar, *mannitan,* $C_6H_{12}O_5$, by assimilation of H_2O. The formation of quinovic acid takes place more easily if kinovin is placed in contact with sodium amalgam and spirit of wine, when after 12 hours mannitan and sodium quinovate are formed. (*Pharmacographia,* 2d ed., p. 364.)

Liebermann and Giesel (*Ber. d. Chem. Ges.*, xvi, 987) believe that two modifications exist, *α-quinovin and β-quinovin,* the former in Cinchona, the latter in Cuprea bark: α-quinovin is a white crystalline powder, nearly insoluble in cold and hot water, but soluble in caustic alkalies, lime water, ammonia water, and glacial acetic acid, soluble with difficulty in chloroform, ether, and petroleum benzin; it dissolves in 57 parts of nearly absolute alcohol. β-quinovin closely resembles α-quinovin, but is not soluble in ether, and crystallizes readily from diluted alcohol.

De Vrij proposes the following method of isolating quinovin. Macerate powdered cinchona with a very weak solution of potassium or sodium hydroxides, precipitate the filtered liquid with an acid, redissolve the precipitate in milk of lime to separate the cinchonic red, filter and precipitate the solution boiling hot with hydrochloric acid, separate the precipitate, wash it, express as much as possible, and lastly dry it on porous stones, and powder it. For a process for preparing quinovin from by-products, see Allen's *Organic Analysis,* 1892, vol. iii, Part II, p. 443. Thus prepared, the quinovic bitter forms soluble compounds with magnesia and lime, and has been employed, in this mode of combination, as a tonic. (*J. P. C.*, April, 1860, p. 258.)

Quinovic Acid (*Kinovic Acid*).—Resulting from the decomposition of quinovin, and possessing the formula $C_{32}H_{48}O_6$; in white, rhomboidal crystals, insoluble in water, but slightly soluble in ether, somewhat more so in boiling alcohol, but very soluble in ammonia and the fixed alkalies, the solutions frothing like soap water. On adding an acid to an alkaline solution of quinovic acid, a hydrate of quinovic acid is thrown down as a very voluminous jelly, the whole contents of the vessel gelatinizing. Kerner (*Deutsche Klin.*, xx, 81) recommends quinovic acid as an excellent tonic, which produces no narcotic symptoms. He prefers it in the form of calcium quinovate, of which forty grains (2.6 Gm.) is the average dose. (*Am. J. M. S.*, Oct., 1869, 543.)

By the experiments of Henry, Jr., and Plisson, it may be considered as established that the alkaloids of the different varieties of bark are combined at the same time with quinic acid and with one or more of the coloring matters which, in relation to these substances, appear to act the part of acids. This idea was originally suggested by Robiquet. (*J. P. C.*, xii, 282, 369.) The compounds of quinine, cinchonine, etc., with the coloring matter are scarcely soluble in water, while their quinates are very soluble.

The odor of bark appears to depend on a *volatile oil,* which Fabroni and Trommsdorff obtained by distillation with water. The oil floated on the surface of the water, was of a thick consistence, and had a bitterish, acrid taste, with the odor of bark.

Yellow Coloring Matter.—This has little taste, is soluble in water, alcohol, and ether, precipitates neither gelatin nor tartar emetic, and is itself precipitated by lead subacetate.

Incompatibles.—Of the relations of bark to the several solvents employed in pharmacy we shall speak hereafter, under the heads of its tincture and other preparations, where we shall also have an opportunity of mentioning some of the more prominent substances which afford precipitates with its liquid preparations. It is sufficient at present to state that all the substances which precipitate the infusion of bark do not by any means necessarily affect its virtues, as it contains several inert ingredients which form insoluble compounds with bodies that do not disturb its active principles.

As *tannic acid* forms with the alkaloids compounds insoluble in water, it is desirable that substances containing this acid in a free state should not be prescribed in connection with the infusion or decoction of bark; for, though these insoluble tannates might be found efficacious if administered, yet, being precipitated from the liquid, they would be likely to be thrown away as dregs, or at any rate would communicate, if agitated, an unpleasant turbidity. The same may be said of the *tincture* and *compound solution of iodine,* which form insoluble compounds with all the cinchona alkaloids, and of the *alkalies, alkaline carbonates,* and *alkaline earths,* which precipitate them from their aqueous solution.

Estimation of Value.—*Grahe's Test.*—A test of the cinchona barks containing one or more of their characteristic alkaloids has been proposed by Grahe. It is founded on the fact that when these barks are exposed to destructive distillation a product is obtained of a bright carmine color, which is yielded by no other bark under the same circumstances, and not by cinchona unless it contain one or more of its peculiar alkaloids. Nor do the pure alkaloids afford it; but, if mixed with a little acetic, quinic, tannic, citric, or tartaric acid, they exhibit the reaction, showing that in the bark it takes place between the alkaloids and organic acids contained in it. Grahe applies the test by heating a piece of the bark weighing from five to ten grains in an ordinary test tube, and gradually increasing the heat to redness. Whitish smoke, and aqueous vapor condensing on the surface of the tube, are first given off, which are soon followed by the appearance of redness in the fumes, and by the deposition, an inch above the heated part, of a red pulverulent film, which is gradually changed into a thick, oily liquid, running down the glass in drops or streaks of a fine carmine color. (*Ch. Cb.,* Feb. 17, 1858, p. 97.)

It is impossible to state with accuracy the relative proportion of the active ingredients in the different varieties of cinchona, as the quantity is by no means uniform in different specimens of the same variety. The results of the most recent experiments have been already stated under the head of the several varieties of bark described. But the medicinal efficiency is measured by the quantity of the peculiar cinchona alkaloids it may contain. In 1880 the U. S. Pharmacopœia for the first time in its history gave a process for assaying cinchona bark; this was deemed necessary because of the impossibility of judging of the quality of the bark by its physical appearances.

Assay.—The Pharmacopœial assay for cinchona is as follows: "Introduce 5 Gm. of Cinchona, in No. 40 powder, into a 500 mil flask and add 200 mils of a mixture of chloroform, 1 volume, and ether, 2 volumes. Stopper the flask, shake it well, and let it stand ten minutes. Then add 5 mils of ammonia water, shake the flask frequently for one hour, and let it stand from eight to ten hours. Now add 10 mils of distilled water, shake the mixture vigorously and when the drug has settled, decant 160 mils of the solution, representing 4 Gm. of Cinchona. Filter it through a pledget of purified cotton into a separator, and rinse both cylinder and cotton with ether. Completely extract the alkaloids from the chloroform-ether solution by shaking out repeatedly with weak sulphuric acid. Collect the acid solutions in a separator, add ammonia water until the solution is distinctly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with chloroform. Filter each portion of chloroform as it comes from the separator through a pledget of purified cotton into a tared flask, and wash the funnel and cotton with chloroform. Evaporate the chloroform on a water bath, add 5 mils of alcohol to the residue, and again evaporate. Repeat the evaporation with alcohol and dry the residue at 100° C. (212° F.) to constant weight. The weight will be the amount of total alkaloids from 4 Gm. of Cinchona. (See Proximate Assays, Part III.)" *U. S.*

Under Red Cinchona the U. S. requirements are: "Proceed as directed under *Cinchona,* using 5 Gm. of Red Cinchona;" the British directions are as follows:

Test.—"Red Cinchona Bark when used for official purposes other than the preparation of alkaloids or their salts, is required to yield from 5 to 6 per cent. of total alkaloids, of which not less than one-half consists of quinine and cinchonidine, as determined by the following process: Mix 10 grammes of Red Cinchona Bark, in No. 60 powder, with 6 grammes of *calcium hydroxide;* add 22 millilitres of *water,* mix intimately in a small porcelain dish or mortar, and set aside for an hour or two. Transfer this mixture to a suitable flask fitted with a reflux condenser, add 130 millilitres of *benzolated amylic alcohol,* boil for about half an hour, and then decant the liquid on to a filter, leaving the sediment in the flask; add more of the *benzolated amylic alcohol* to the sediment, and boil and decant as before; repeat this operation a third time; then transfer the contents of the flask to the filter, and wash by percolation with more of the *benzolated amylic alcohol* until the Bark is exhausted. Introduce the collected filtrate, while still warm, into a stoppered glass separator; add to it 2 millilitres of *diluted hydrochloric acid,* mixed with 12 millilitres of *water;* shake well together, and allow the liquids to separate; draw off the acid liquid, and repeat the process with *water* slightly acidified with *hydrochloric acid,* until the alkaloids have been completely removed. Carefully and exactly neutralise the acid liquid, while warm, with *solution of ammonia,* and concentrate by evaporation to the bulk of 16 millilitres. To the concentrated solution add about 1.5 grammes of *sodium potassium tartrate,* dissolved in twice its weight of *water,* stirring with a glass rod; after about one hour collect the precipitate, wash dry at 100° C. (212° F.)

and weigh; the weight in grammes multiplied by 8 gives the percentage of quinine and cinchonidine in the Bark. To the mother-liquor and washings from the preceding process add *solution of ammonia* in slight excess and shake with three successive portions of 10 millilitres of *chloroform;* evaporate the mixed chloroformic solutions to dryness, dry the residue at 110° C. (230° F.) and weigh. The weight in grammes multiplied by 10 and added to the percentage of the quinine and cinchonidine, gives the percentage of total alkaloids." *Br.*

The German Pharmacopœia gives the following method: "The powdered bark is assayed as follows: Shake 20 Gm. of it strongly and repeatedly with a mixture of 10 Gm. of water of ammonia, 20 Gm. of alcohol, and 170 Gm. of ether, and, after a day, decant 120 Gm. of the clear liquid. To this liquid add 3 Cc. of volumetric hydrochloric acid, remove the ether by distillation or evaporation, and again add, if necessary, enough hydrochloric acid to render the solution acid. Then filter, and mix the cold filtrate with 3.5 Cc. of volumetric solution of potassa. When the alkaloids have subsided, drop more of the solution of potassa into the clear supernatant liquid, until nothing more is thrown down. Finally, collect the whole of the precipitate on a filter, and wash it repeatedly with small portions of water, until drops of the wash water allowed to come in contact with the surface of a cold, aqueous, neutral, saturated solution of sulphate of quinine no longer produce a turbidity. When the alkaloids have drained, press them gently between bibulous paper, and, having dried them sufficiently in the air to permit their being removed to a watch-glass, dry them completely, first over sulphuric acid, and, finally, by means of a water-bath. The weight of alkaloids procured by this method should not be less than 0.42 Gm. When a small portion of the same is boiled with 300 parts of water, the filtrate, after cooling, should yield flakes of quinine. When to 5 parts of this solution, after being cooled and decanted, 1 part of chlorine water is added, and water of ammonia immediately dropped in, the liquid should acquire a beautiful green color." For E. R. Squibb's method of assay, see *U. S. D.*, 18th ed., p. 412.

It is usually sufficient to ascertain the quantity of total alkaloids in bark, for this is really a test of the efficacy of the bark for pharmaceutical purposes, since all the organic alkaline principles contained in it are efficient as medicines, and in all probability in a nearly equal degree. But for manufacturing purposes it is necessary to push the investigation further, and ascertain the proportion of the several alkaloids in the mixture.

De Vrij obtained from bark of *C. officinalis* grown at Ootacamund total alkaloids as high as 11.96 per cent. (9.1 per cent. of which was quinine). The highest yield yet recorded was obtained by De Vrij from Ootacamund bark, 13.5 per cent., the great part of which was quinine. Between these and the barks of lowest value there is every grade of productiveness, down to a mere trace of alkaloidal matter. Under the name of *quinetum* a compound is produced in India and other Eastern countries, which consists of the mixed alkaloids of Red Bark, the object being to produce a cheap febrifuge which will answer all practical purposes and save the cost of refining. (See U. S. Dispensatory, 19th edition, p. 359.) *Febrifuge.*—Under this name, the British Indian government introduced a manufactured product, designed to furnish a cheap but valuable substitute for quinine sulphate. It is largely produced at Sikkim, India, by a modification of Dubreuil's process, which consists in extracting the powdered mixed barks with hydrochloric acid, precipitating the alkaloids by the addition of solution of sodium hydroxide, and shaking out with petroleum, adding to the petroleum solution a calculated quantity of diluted sulphuric acid, evaporating and crystallizing.

Uses.—This valuable remedy was unknown to the civilized world until about the middle of the seventeenth century, though the natives of Peru are generally supposed to have been long previously acquainted with its febrifuge powers. Humboldt, however, is of a different opinion. In his memoir on the Cinchona forests, he states that it is unknown as a remedy to the Indians inhabiting the country where it grows, and, as these people adhere pertinaciously to the habits of their ancestors, he concludes that it never was employed by them. They have generally the most violent prejudices against it, considering it poisonous, and in the treatment of fever prefer the milder indigenous remedies. Ruiz and Pavon, however, ascribe the discovery to the Indians; and Tschudi states, in his *"Travels in Peru"* (Am. ed., ii, 280), that the inhabitants of the Peruvian forests drink an infusion of the green bark as a remedy in intermittent fever. On the other hand, the statements of Humboldt have been confirmed by the travellers Markham and Spence, the former remarking that the native Indian doctors did not use the bark, and the latter that the Cascarilleros of Ecuador believed that their red bark is used solely for dyeing. It is uncertain whether, as Jussieu stated in 1739, the Jesuit fathers received their knowledge from the Indians, or, as Humboldt believes, discovered the virtues of the drug for themselves, having been led to make trial of it by its extreme bitterness. The Countess Chinchon, wife of the Viceroy of Peru, having in her own person experienced the beneficial effects of the bark is said, on her return to Spain in the year 1640, to have first introduced the remedy into Europe. Hence the name of *pulvis Comitissæ*, by which it was first known. After its introduction it was distributed and sold by the Jesuits, who are said to have obtained for it the price of its weight in silver. From this circumstance it was called *Jesuits' powder*, a title which it long retained. In 1653, Chifflet, physician to the Archduke Leopold, directed

the attention of all Europe to the bark by his work entitled *Pulvis Febrifugus Orbis Americani.* This gave rise to a very active controversy, the high price of the drug aiding very greatly those who opposed its introduction. According to Sturm, twenty doses in 1658 cost sixty florins. It seems first to have been advertised in England for sale in 1658 by a James Thomson, and by 1660 it was much employed. It still, however, encountered much prejudice and ignorance, and was not made official in the London Pharmacopœia until 1677. Sir Robert Talbot (or Talbor) used it as a secret remedy with so much address and success that in 1679 he cured Charles II of a tertian, and subsequently sold his secret to Louis XIV of France, who published it in 1681.

When taken into the stomach, the bark usually excites in a short time a sense of warmth in the epigastrium, which often diffuses itself over the abdomen and even the breast, and is sometimes attended with considerable gastric and intestinal irritation. Nausea and vomiting are sometimes produced, especially if the stomach was previously in an inflamed or irritated state; and its action is not unfrequently accompanied by purging. If the dose of the cinchona bark has been large enough, the symptoms of cinchonism may result. (See *Quinina.*) At one time cinchona bark and its preparations were used as antiperiodics, but at present for such purpose one of its alkaloids is always selected. The best preparation for use as a tonic is the compound tincture.

Dose, ten grains to one drachm (0.65–3.9 Gm.).

CINCHONIDINÆ SULPHAS. U. S.

CINCHONIDINE SULPHATE Cinchonid. Sulph.

(cĭn-ĉhǫ-nĭ-dĭ'næ sŭl'phās)

"The sulphate [$(C_{19}H_{22}ON_2)_2.H_2SO_4 + 3H_2O = 740.53$] of an alkaloid obtained from the bark of several species of cinchona. Preserve it in well-closed containers protected from light." *U. S.*

Cinchonidinum sulfuricum; Sulphate of Cinchonidine; Schwefelsaures Cinchonidin, Cinchonidinsulfat, *G.;* Sulfate de Cinchonidine basique, *Fr.;* Solfato di cinconidina, *It.*

This salt is prepared from the mother liquors obtained in the manufacture of quinine sulphate, and is separated from the sulphates of the other alkaloids by fractional crystallization. The British-India and Javanese cultivated red barks usually contain large quantities of cinchonidine. Of the South American barks, probably the Colombian varieties yield the largest proportion of cinchonidine. Owing to some confusion in naming cinchonidine and quinidine, this alkaloid is sometimes incorrectly called in Germany *chinidine.* Skraup's researches on the composition of cinchonine and cinchonidine (1879) established the correctness of the formula $C_{19}H_{22}ON_2$, instead of the long-accepted formula of Pasteur (1853), $C_{20}H_{24}ON_2$. Skraup's formula has been confirmed by Hesse, and is generally accepted by chemists.

Properties.—Cinchonidine sulphate occurs in "white, glistening, silky needles or prisms; odorless and having a very bitter taste; permanent in the air. One Gm. of Cinchonidine Sulphate dissolves in 65 mils of water, 90 mils of alcohol, and in 620 mils of chloroform at 25° C. (77° F.); also in 22 mils of water at 80° C. (176° F.), and in 41 mils of alcohol at 60° C. (140° F.); nearly insoluble in ether. A saturated aqueous solution of the salt is neutral or faintly alkaline to litmus and is lævorotatory. When anhydrous it melts at about 200° C. (392° F.) with partial decomposition. An aqueous solution of Cinchonidine Sulphate yields with barium chloride T.S., a white precipitate, insoluble in hydrochloric acid. Add ammonia water to 25 mils of an aqueous solution of the salt, 1 in 80; a white precipitate (*cinchonidine*) is produced, which is but slightly soluble in ammonia water, but which, when freshly precipitated, dissolves in 5 mils of ether, the greater part afterwards separating in crystals. When dried to constant weight at 100° C. (212° F.), Cinchonidine Sulphate loses not more than 12 per cent. of its weight. Incinerate about 1 Gm. of Cinchonidine Sulphate; not more than 0.1 per cent. of ash remains. Add 2 mils of sulphuric acid to about 0.1 Gm. of the salt; not more than a faint, yellow color is developed (*readily carbonizable impurities*). Ten mils of a solution of the salt (1 in 1000) in diluted sulphuric acid exhibits only a faint, blue fluorescence. Macerate 0.5 Gm. of Cinchonidine Sulphate, with frequent agitation, at the ordinary temperature, with 20 mils of distilled water, then add 0.5 Gm. of potassium and sodium tartrate and continue the maceration with repeated agitation for one hour at 15° C. (59° F.), and filter the mixture. The addition of 1 drop of ammonia water to the filtrate produces not more than a slight turbidity (*cinchonine or quinidine sulphate*).

Cinchonidine.—The alkaloid itself is not official; as usually seen it is in white, light, pulverulent masses. It is crystallizable, soluble in 1680 parts of cold and in a somewhat smaller quantity of hot water, in about 20 parts of alcohol, and in 70 parts of ether. It melts at 206.5° C. (404° F.), and on cooling becomes a solid mass of crystals at 190° C. (374° F.). The *acid sulphate* (sometimes called *bisulphate*) is much more soluble in water than the official sulphate. *Cinchonidine salicylate* is neutral and crystalline, insoluble in cold water, sparingly

in hot water, easily soluble in alcohol and diluted alcohol. It may be prepared by the direct combination of salicylic acid with the alkaloid. The *hydrobromide* has been employed by Gubler hypodermically. Königs and Husmann having claimed to have converted cinchonine into cinchonidine by the long-continued action of boiling amyl alcohol and solution of potassium hydroxide, Paul and Cownley have investigated this treatment. They failed to get such conversion, and consider that the cinchonine used by Königs and Husmann must have been impure. (*P. J.*, Feb. 20, 1897.)

Uses.—So far as our knowledge goes, this alkaloid influences the system similarly to quinine, the only difference being that it is less powerful. It may be given in doses one-third greater than those of quinine, but should not be relied on in severe cases.

Dose, five to ten grains (0.32–0.65 Gm.).

CINCHONINÆ SULPHAS. U. S.

CINCHONINE SULPHATE Cinchonin. Sulph.

(cĭn-ĉhŏ-nī'næ sŭl'phăs)

"The sulphate [$(C_{19}H_{22}ON_2)_2.H_2SO_4 + 2H_2O = 722.51$] of an alkaloid obtained from the bark of several species of cinchona. Preserve it in well-closed containers protected from light." *U. S.*

Cinchoniæ Sulphas, *Pharm.* 1870; Sulfate de Cinchonine basique, *Fr. Cod.*; Schwefelsaures Cinchonin, Cinchoninum Sulfuricum, Cinchoninsulfat, *G.*; Solfato cinchonico, *It.*; Sulfato de cinconina, *Sp.*

The U. S. P. 1870 process for making Cinchonine Sulphate was as follows: "Take of the mother-water, remaining after the crystallization of Sulphate of Quinine, in the process for preparing that salt, a *convenient quantity;* Solution of Soda, Alcohol, Diluted Sulphuric Acid, Animal Charcoal, in fine powder, each *a sufficient quantity.* To the mother-water add gradually, with constant stirring, Solution of Soda, until the liquid becomes alkaline. Collect on a filter the precipitate formed, wash it with water, and dry it. Then wash it with successive small portions of alcohol, to remove other alkaloids which may be present. Mix the residue with eight times its weight of water, and, having heated the mixture, add gradually Diluted Sulphuric Acid until it is saturated and becomes clear. Then boil the liquid with Animal Charcoal, filter it while hot, and set it aside to crystallize. Lastly, drain the crystals, and dry them on bibulous paper. By evaporating the mother-liquid, more crystals may be obtained." *U. S.* 1870.

In consequence of its greater solubility, cinchonine sulphate remains behind in the mother water, when quinine sulphate crystallizes, in the process for preparing the latter salt. To separate it from other substances contained in the mother water, it is decomposed by solution of soda, which is preferable to potassa, as it forms a very soluble salt with sulphuric acid, whereas the potassium sulphate, being of difficult solubility, might fall with the precipitated cinchonine. The precipitate may be safely washed with small portions of alcohol, as the alkaloid is almost insoluble in that liquid when cold. It is next reconverted into the sulphate, and the solution, having been boiled with *unpurified* animal charcoal to decolorize it, and at the same time neutralize any possible excess of sulphuric acid which might interfere with the crystallization of the salt, is filtered while hot, and then allowed to stand. It is particularly important that there should be no excess of sulphuric acid while the solution is exposed to heat, as under this influence the alkaloid is much disposed to become uncrystallizable. Hence the advantage of using unpurified animal charcoal or bone black, as the calcium carbonate contained in it neutralizes any excess of the acid. The cinchonine sulphate, held in solution by the liquid while hot, is deposited by it, upon cooling, in crystals.

It may be also prepared by first obtaining cinchonine directly from one of the barks, treating this with water acidulated with sulphuric acid, added gradually until the alkaloid is dissolved, then boiling with purified animal charcoal, filtering the solution while hot, and setting it aside to crystallize.

There are two cinchonine sulphates, the neutral and the acid sulphate. The official salt is the neutral sulphate. It is in "white, lustrous prismatic crystals; odorless, and having a very bitter taste; permanent in the air. One Gm. of Cinchonine Sulphate dissolves in 60 mils of water, 12.5 mils of alcohol, 47 mils of chloroform, and in 3230 mils of ether at 25° C. (77° F.); also in 33 mils of water at 80° C. (176° F.), and in 7 mils of alcohol at 60° C. (140° F.). A saturated aqueous solution of the salt is neutral or slightly alkaline to litmus and is dextrorotatory. An aqueous solution of Cinchonine Sulphate (1 in 100) yields with barium chloride T.S. a white precipitate insoluble in hydrochloric acid. Dried to constant weight at 100° C. (212° F.) Cinchonine Sulphate loses not more than 5 per cent. of its weight. Incinerate about 1 Gm. of Cinchonine Sulphate; not more than 0.1 per cent. of ash remains. Ten mils of a solution of the salt (1 in 1000) in diluted sulphuric acid exhibits only a slight, blue fluorescence. One-tenth Gm. of the powdered salt dissolves completely or nearly so when shaken with 10 mils of chloroform at ordinary temperatures (*quinine or cinchonidine sulphate*). Add 0.1 Gm. of the salt to 2 mils of sulphuric acid; it imparts not more than a faint, yellow tinge to the acid (*readily carbonizable, organic impurities*)." *U. S.* The *acid sulphate*, or *bisulphate*, $C_{19}H_{22}ON_2.H_2SO_4.3H_2O$, is prepared by adding sulphuric acid to the neutral sulphate. According to Baup, 100 parts are soluble in 45 parts of absolute alcohol; it is insoluble in ether. It crystallizes in rhombic octohedrons.

Cinchonine (Cinchonina *U. S.*, 1890), $C_{19}H_{22}ON_2 = 294.20$, was introduced into the U. S. P., 1880, but not admitted in the 8th or 9th Revisions. Several processes have been employed for the preparation of cinchonine. One of the simplest is the following: Powdered pale bark is submitted to the action of sulphuric or hydrochloric acid very much diluted, and the solution obtained is precipitated by an excess of lime. The precipitate is collected on a filter, washed with water, and treated with boiling alcohol. The alcoholic solution is filtered while hot, and deposits the cinchonine when it cools. A further quantity is obtained by evaporation. If not perfectly white, it may be made so by converting it into a sulphate with diluted sulphuric acid, then treating the solution with animal charcoal, filtering, precipitating by an alkali, and redissolving in alcohol in the manner already mentioned. It may also be obtained from the mother waters of quinine sulphate by diluting them with water, precipitating with ammonia, collecting the precipitate on a filter, washing and drying it, and then dissolving it in boiling alcohol, which deposits the cinchonine in a crystalline form upon cooling. It may be still further purified by a second solution and crystallization. Its formula is now generally accepted as $C_{19}H_{22}ON_2$, the molecular weight of which is 292.03, as proposed by Skraup, instead of the older formula, $C_{20}H_{24}ON_2$, of Pasteur. This alkaloid occurs in "white, lustrous prisms or needles, without odor, at first almost tasteless, but soon developing a bitter after-taste; permanent in the air. Soluble, at 15° C. (59° F.), in 3760 parts of water, and in 116 parts of alcohol; in 3500 parts of boiling water, and in 26.5 parts of boiling alcohol. Also soluble in 526 parts of ether, and in 163 parts of chloroform. At 240° C. (464° F.) the crystals fuse together, and at 258° C. (496.4° F.) they melt, forming a brown liquid. When ignited, they are consumed without leaving a residue. When placed on moistened, red litmus paper, Cinchonine shows an alkaline reaction. On adding to a neutral or not more than faintly acid solution of Cinchonine, or of any of its salts, enough potassium ferrocyanide test-solution to redissolve the precipitate first formed, and afterwards an acid, a golden-yellow precipitate will be formed, which, when redissolved by gently warming the liquid, will separate, on cooling, in minute scales or needles. On adding an excess of ammonia water to a solution of Cinchonine in a diluted acid, the alkaloid will be precipitated. The precipitate is but feebly soluble in ammonia, and should require not less than 300 parts of ether for solution. A solution of Cinchonine (1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (absence of more than traces of *quinine* or *quinidine*). Cinchonine should not impart more than a faintly yellowish tinge to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*)." *U. S.* 1890. Waddington found it to sublime readily, without change, in perfectly characteristic crystals. (*P. J.*, March, 1868, p. 414.) Its alkaline character is very decided, as it neutralizes the strongest acids. Of the salts of cinchonine, the sulphate, nitrate, hydrochloride, phosphate, and acetate are soluble in water. The neutral tartrate, oxalate, and gallate are insoluble in cold water, but soluble in hot water, alcohol, or an excess of acid. Winckler has shown that cinchonine is rendered uncrystallizable or amorphous by sulphuric acid in excess, aided by heat, a fact of importance in the preparation of the sulphate of this alkaloid. Cinchonine is but little more soluble in carbonic acid water than in pure water, and does not, like quinine, yield crystals of the carbonate on exposure of its carbonic acid solution. It differs from quinine by its rotating the plane of polarization to the right, by the want of fluorescence in its solutions, and by its failing to respond to the thalleioquin test.

Exposed to the air, cinchonine does not suffer decomposition, but very slowly absorbs carbonic acid gas, and acquires the property of effervescing slightly with acids. It is precipitated sulphur yellow by gold trichloride. Chlorine water dissolves it or any of its salts without change; but if ammonia be now added, a white precipitate is produced. It is thus distinguishable from quinine. (See *Quinina.*) J. W. Bill, U. S. A., proposed potassium, ferrocyanide as a very delicate test of cinchonine. If added to the solution of a salt of this alkaloid, it produces a yellowish-white curdy precipitate, which is dissolved upon the application of a gentle heat, but is again deposited, when the liquid cools, as an abundant crop of golden-yellow crystals. No other alkaloid exhibits the same reaction. A cloudy precipitate is produced by the same reagent with a salt of quinine; but this does not happen when the ferrocyanide is in excess; and, if the precipitate be dissolved by heat, no subsidence takes place on cooling. Hence, in the application of this test to cinchonine, a slight excess of the ferrocyanide should be added.

By the action of potassium permanganate cinchonine is decomposed, with the effect of producing, at first, an entirely distinct neutral principle, *cinchotenine*, $C_{18}H_{20}O_3N_2 + 3H_2O$, and an alkaloid, which the authors named *hydrocinchonine*, $C_{19}H_{24}ON_2$, as it differs from cinchonine (cinchonia) only in having two additional atoms of hydrogen. The cinchotenine, when further oxidized by the same reagent, yields quinoline and pyridine derivatives (see Part II), as *cinchonic* (quinoline-carboxylic) *acid*, $C_9H_6N(COOH)$, and *cinchomeronic* (pyridine-dicarboxylic) *acid*, $C_5H_3N(COOH)_2$.

Uses.—Cinchonine sulphate has the same remedial properties as quinine sulphate, but must be given in somewhat larger dose. It may be taken in pill, or in solution made by the addition of diluted sulphuric acid in the proportion of a minim or two drops for each grain of the salt. To lessen the bitterness in taste, it may

be given suspended in syrup, without the use of any acid or with a few grains of powdered licorice added to the mixture.

Dose, tonic, a grain or two (0.065–0.13 Gm.) three or four times a day; antiperiodic dose, fifteen to forty grains (1.0–2.6 Gm.) between the paroxysms.

Both *cinnamomum* and *cassia* were terms employed by the ancients, but whether exactly as now understood it is impossible to determine. The term *cassia*, or *cassia lignea*, has been generally used in modern times to designate the commoner barks of *Cinnamomum Cassia* (Nees) Blume. The barks sold as cinnamon and cassia in different parts of the world are derived from various species of Cinnamomum.

Cinnamomum zeylanicum is a tree about 20 or 30 feet high, covered with a thick, scabrous bark. The branches are numerous, strong, horizontal, and declining, and the young shoots are beautifully speckled with dark green and light orange colors. The leaves are petiolate, opposite for the most part, coriaceous, entire, ovate or ovate-oblong, obtusely pointed, and three-nerved, with the lateral nerves vanishing as they approach the point. There are also two less obvious nerves, one on each side arising from the base, proceeding towards the border of the leaf, and then quickly vanishing. In one variety the leaves are very broad and somewhat cordate. When mature, they are of a shining green upon their upper surface, and lighter-colored beneath. The flowers are small, white, and arranged in axillary and terminal panicles. The fruit is an oval berry, which adheres like the acorn to the receptacle, is larger than the black currant, and when ripe has a bluish-brown surface, diversified with numerous white spots. The tree emits no odor perceptible at any distance. The bark of the root has the odor of cinnamon with the pungency of camphor, and yields this principle upon distillation. The leaves have a spicy odor when rubbed, and a hot taste. A volatile oil has been distilled from them. The petiole has the flavor of cinnamon. It is a singular fact that the odor of the flowers is to most persons disagreeable, being compared by some to the scent exhaled from newly-sawed bones. The fruit has a terebinthinate odor when opened, and a taste in some degree like that of juniper berries. A fatty substance, called *cinnamon-suet*, is obtained from it when ripe, by bruising it and then boiling it in water, and removing the oleaginous matter which rises to the surface, and concretes upon cooling. It is the prepared bark that constitutes the genuine cinnamon.

This species is a native of Ceylon, where it has long been cultivated. It is said also to be a native of the Malabar Coast, and has at various periods been introduced into Java, the Isle of France, Bourbon, the Cape Verds, Brazil, Cayenne, several of the West India islands, and Egypt, and in some of these places is at this time highly productive, especially in Cayenne, where the plant was flourishing so early as 1755. It is exceedingly influenced, as regards the aromatic character of its bark, by the circumstances of soil, climate, and mode of culture. Thus, we are told by Marshall that in Ceylon, beyond the limits of Negombo and Matura, in the western and southern parts of the island, the bark is never of good quality, being greatly deficient in the aromatic flavor of the cinnamon, and that even within these limits it is of unequal value, from the various influences of exposure, soil, shade, and other circumstances. Cinnamon closely resembling Ceylon cinnamon is said to have been sent to Europe from Brazil.

Cassia Cinnamon which was formerly official is the product of *Cinnamomum Cassia* (Nees) Blume, a tree resembling *C. Zeylanicum* but distinguished by the hairiness of the young twigs, petioles and under surfaces of the leaves. The tree is indigenous to and cultivated in southern China, Annam and Cochin-China. It is also cultivated in Sumatra, Ceylon, Japan, Mexico and South America. The bark is known in commerce as *China* or *Canton Cassia* and the commonest or cheapest grade as "*Cassia lignea.*"

Besides the two species above described, others have been thought to contribute to the cinnamon and cassia of commerce. In 1839 (*Madras Journ. Lit. and Sci.*, No. 22), Wight stated that in his belief cinnamon was derived from 12 to 18 specifically distinct trees. *C. inners*, Reinw., is distinguished from *C. zeylanicum* by the nervation of its leaves, which are also paler and thinner than those of the official plant, of which, however, it is probably only a variety.

It yields the so-called *wild cinnamon* of Japan. *C. obtusifolium* Nees, growing in Ceylon, Java, and on the mainland of India, is said to have been the chief source of the drug known formerly by the name of *Folia Malabathri* and consisting of the leaves of different species of Cinnamomum mixed together. *C. Culilawan* Blume of the Moluccas yields the aromatic bark called culilawan, noticed in Part II of this work; and similar barks are obtained from *C. Sintoc* of Java. *Massoy bark,* from which an aromatic volatile oil is obtained called *oil of massoy,* is the product of *Sassafras Goesianum* Leijom. In the mountains of Eastern Bengal, at a height of 1000 to 4000 feet, flourish *C. obtusifolium* Nees, *C. pauciflorum* Nees, and *C. Tamala* Nees et Ebern, and these, with other unknown species, afford quantities of bark which are shipped from Calcutta, Java, Timor, etc., to Europe under the name of *wild cassia.* The bark of the *C. pedatinervium* Meissn, a tree indigenous to Fiji, yields nearly one per cent. of a white aromatic volatile oil, with a pungent spicy taste. For constitution, etc., see *Proc. Chem. Soc.,* xix. These barks are mostly highly aromatic, resembling cinnamon more or less closely in flavor, and are distinguished by yielding to cold water an abundant mucilage. Holmes described the bark of *C. pedativum* Meis., and concludes that it might be of value as a source of safrol and linalool in *P. J.,* 1904, p. 892.

Cassia Buds.—This spice consists of the calyx of *Cinnamomum Cassia* (Nees) Blume, surrounding the young ovary, and, as stated by Martius, on the authority of the elder Nees, about one-quarter of the normal size. It is produced in China; and Reeves states that great quantities of it are brought to Canton from the province which affords cassia. Cassia buds have some resemblance to cloves, and are compared to small nails with round heads. The enclosed ovary is sometimes removed, and they are then cup-shaped at top. They have a brown color, with the flavor of cinnamon, and yield an essential oil upon distillation. They may be used for the same purposes as the bark.

Culture, Collection, Commerce, etc.—In Ceylon, cinnamon bark was originally collected exclusively from the tree in a wild state; but the Dutch introduced the practice of cultivating it, which has been continued since the British came into possession of the island. The principal cinnamon gardens are in the vicinity of Colombo, but the plant is grown from the sea-level up to a considerable elevation, giving the finest product, however, on the sandy soil of the coast line. The seeds are planted in a prepared soil at certain distances, and, as four or five are placed in a spot, the plants usually grow in clusters like the hazel-bush. In favorable situations they attain the height of five or six feet in six or seven years; and a healthy bush will then afford two or three shoots fit for peeling, and every second year afterwards from four to seven shoots in a good soil. The cinnamon harvest commences in May and continues until late in October. The first object is to select shoots proper for decortication, and those are seldom cut which are less than half an inch or more than two or three inches in diameter. Before decortication these shoots are trimmed up, and the small pieces, when dried, constitute *cinnamon chips.* The bark is divided by longitudinal incisions, of which two are made in the smaller shoots, several in the larger, and is then removed in strips by means of a suitable instrument. The pieces are next collected in bundles, and allowed to remain in this state for a short time, so as to undergo a degree of fermentation, which facilitates the separation of the epidermis. This, with the green matter beneath it, is removed by placing the strip of bark upon a convex piece of wood and scraping its external surface with a curved knife. The bark now dries and contracts, assuming the appearance of a quill. The peeler introduces the smaller tubes into the larger, and connects them also endwise, thus forming a congeries of quills which is about forty inches long. When sufficiently dry, these cylinders are collected into bundles weighing about thirty pounds and bound together by pieces of split bamboo. The commerce in Ceylon cinnamon was formerly monopolized by the East India Company; but the cultivation is now unrestricted, and the bark may be freely exported upon the payment of a fixed duty. It is assorted in the island into three qualities, distinguished by the designations of *first, second,* and *third.* The inferior kinds, which are of insufficient value to pay the duty, are used for preparing oil of cinnamon.

The importations of *cassia buds* into the United States in 1916 amounted to 197,056 pounds, and of *cassia* and *cassia leaves* to 7,487,156 pounds, valued at $493,161. Immense quantities of cinnamon barks are exported from China, the finest of which is little inferior to that of Ceylon, though the mass of it is much coarser. It passes in commerce under the name of *cassia,* was formerly official, and is said by Reeves to be brought to Canton from the province of Kwangse, where the tree producing it grows very abundantly. It is, indeed, asserted that true cinnamon of very fine grade occurs in China, although it never enters foreign commerce, because of the high price which it commands at home. (*P. J.,* xxi, 1890.) These fine cinnamons are said to be produced in the mountainous district of Annam, or Cochin-China. Cinnamon of good quality is said to be collected in Java, and considerable quantities of inferior quality have been thrown into commerce, as *cassia lignea,* from the Malabar Coast. Manila and the Isle of France are also mentioned as sources whence this drug is supplied. Little, however, reaches the United States from these places. The island of Martinique, Cayenne, and several of the West India islands yield to commerce considerable quantities of cinnamon of various qualities. That of Cayenne is of two kinds, one of which closely resembles, though it does not quite equal, the aroma of Ceylon, the other resembles the Chi-

nese. The former is supposed to be derived from plants propagated from a Ceylonese stock, the latter from plants which have sprung from a tree introduced from Sumatra. By far the greater proportion of cinnamon brought to this country is imported from China. It is entered as *cassia* and *Saigon cassia* at the custom house.

From what source the ancients derived their cinnamon and cassia is not certainly known. Neither the plants nor their localities, as described by Dioscorides, Pliny, and Theophrastus, correspond precisely with our present knowledge; but in this respect much allowance must be made for the inaccurate geography of the ancients. It is probable that the Arabian navigators at a very early period conveyed this spice within the limits of the Phenician and Grecian and subsequently of Roman commerce.

Properties.—*Saigon cinnamon* takes its name from Saigon, the capital of French Cochin China. It is a thick cassia bark, which has come into European commerce, and was recognized for the first time by the U. S. P., 1890. It is officially described as "in quills attaining a length of 30 cm., and from 3 to 30 mm. in diameter; the bark from 0.5 to 3 mm. in thickness; outer surface light brown to dark purplish-brown with grayish patches of foliaceous lichens and numerous bud-scars; finely wrinkled, especially the bark of younger twigs, otherwise more or less rough from corky patches surrounding the lenticels; inner surface reddish-brown to dark brown, granular, and slightly striate; fracture short; inner bark porous, owing to the presence of large oil cells and mucilage cells, and separated by a continuous layer of stone cells from the outer bark; odor aromatic; taste sweetish, aromatic and pungent. Under the microscope, sections of the older bark of Saigon Cinnamon show a thin layer of more or less lignified cork cells; a narrow layer of starch-bearing parenchyma with scattered stone cells; a nearly continuous zone, several layers wide, of stone cells, among which are small groups of bast-fibers with thickened and slightly lignified walls; a wide inner bark with medullary rays 1 to 3 cells in width, isolated bast-fibers, mucilage cells, oil cells and parenchyma, the cells of the latter either filled with starch grains or containing very small raphides of calcium oxalate; the lumina of parenchyma cells, stone cells and bast-fibers frequently filled with an amorphous reddish-brown substance, which is for the most part insoluble in the ordinary reagents. In the bark of young twigs there is an epidermal layer with a thick yellowish cuticle, fewer stone cells in the zone associated with bast-fibers, and the inner bark is narrower and with fewer secretion cells than in the older bark. The powder is yellowish- or reddish-brown; starch grains numerous, single or compound, the individual grains being somewhat ellipsoidal or polygonal and from 0.003 to 0.02 mm. in diameter; fragments, with colorless stone cells, rather prominent, the cells being very irregular in shape and the lumina containing either air or a reddish-brown amorphous substance; bast-fibers from 0.3 to 1.5 mm. in length and usually in groups of from 2 to 20 with very thick and scarcely lignified walls; numerous cellular, reddish-brown fragments in which the oil cells are not readily distinguishable. Saigon Cinnamon yields not less than 2 per cent. of volatile extractive, soluble in ether. (See Part III, Test No. 12.) Saigon Cinnamon yields not more than 6 per cent. of ash. The amount of ash insoluble in diluted hydrochloric acid does not exceed 2 per cent. of the weight of Saigon Cinnamon taken." *U. S.*

"In closely rolled quills, each about nine millimetres in diameter, and containing numerous smaller quills or channelled pieces. Dull, pale yellowish-brown, darker on the inner surface; thin, brittle and splintery; entirely free from cork; marked with small scars or holes and with faint, shining, wavy longitudinal lines. The powdered Bark exhibits abundant parenchymatous tissue with brown cell-walls, isolated bast-fibers not more than 30 microns in diameter, small simple or compound starch grains and thick-walled sclerenchymatous cells, but no cork or fragments of wood. Fragrant odor; taste warm, sweet and aromatic. Ash not more than 5 per cent." *Br.*

The odor of this cinnamon is fragrant, the taste is highly aromatic, markedly that of cinnamon, and, in the specimens that we have seen, only slightly astringent. It also occurs in commerce much broken, in which state it commands a somewhat smaller price than in quills. The Saigon buds also are brought into the port of New York. The quality of Saigon cassia, as it is commonly termed in trade journals, is distinctly superior to that of other cassias, and the price which it commands much higher. It is obtained from an undetermined species of Cinnamomum but is sometimes ascribed to *Cinnamomum Loureirii* of Nees, the *Laurus Cinnamomum* of Loureiro, a tree which grows in Cochin-China and Japan. According to Siebold, the bark of the large branches is of inferior quality and is rejected; that from the smallest branches resembles the Ceylon cinnamon in thickness, but has a very pungent taste and odor, and is little esteemed, while the intermediate branches yield an excellent bark, about 2 mm. in thickness, which is even more highly valued than the cinnamon of Ceylon, and yields a sweeter and less pungent oil. It yields about 2 per cent. of a volatile oil, *the oil of Nikkei*, having an odor resembling that of cinnamon and consisting of citral, having a specific gravity at 15° C. (59° F.) of 0.9005, and containing about 27 per cent. of aldehyde, chiefly citral.

Ceylon cinnamon occurs "in closely rolled double quills, composed of from 7 to 12 thin layers of separate pieces of bark, from 30 to 50 cm. in length and from 8 to 13 mm. in diameter; the bark attaining a thickness of 1 mm.; outer surface pale yellowish-brown, smooth, longitudinally striate with narrow yellowish groups of bast-fibers, and showing circular

or irregular brownish patches, occasionally with perforations marking the nodes; inner surface light brown, with faint, longitudinal striations; fracture short with projecting bast-fibers; odor agreeably aromatic; taste sweetish and warmly aromatic. Under the microscope, sections of Ceylon Cinnamon usually show no cork but an almost continuous outer layer of stone cells, among which are small groups of bast-fibers resembling those found in *Saigon Cinnamon;* in the inner bark occur numerous bast-fibers singly or in small groups, medullary rays 1 to 2 cells in width, usually with raphides of calcium oxalate; parenchyma with either reddish-brown contents or more or less filled with starch grains; scattered throughout the parenchyma occur oil secretion cells and mucilage cells. The powder is light brown or yellowish-brown; starch grains numerous, varying from spherical to polygonal, from 0.003 to 0.02 mm. in diameter, frequently in small aggregates; bast-fibers from 0.3 to 0.8 mm. in length, usually single, spindle-shaped, with attenuated ends, the walls being very thick and but slightly lignified; colorless stone cells resembling those of *Saigon Cinnamon;* numerous cellular fragments with yellowish-brown walls or contents; cork cells few or none; calcium oxalate in raphides, from 0.005 to 0.008 mm. in length. Ceylon Cinnamon yields not less than 0.5 per cent. of volatile extractive, soluble in ether. (See Part III, Test No. 12.) Ceylon Cinnamon yields not more than 6 per cent. of ash. The amount of ash insoluble in diluted hydrochloric acid does not exceed 2 per cent. of the weight of Ceylon Cinnamon taken." *U. S.*

When distilled Ceylon Cinnamon affords but a small quantity of essential oil, which, however, has an exceedingly grateful flavor. It is brought to this country from England, but it is costly. The inferior sorts are browner, thicker, less splintery, and of a less agreeable flavor, and are little if at all superior to the best Chinese. The finer variety of *Cayenne cinnamon* approaches in character that above described, but is paler and in thicker pieces, being usually collected from older branches. That which is gathered very young is scarcely distinguishable from the cinnamon of Ceylon.

Chinese cinnamon, or *Cassia* (*Cinnamomum Cassia, Cassia Cinnamon,* U. S., 1890), occurs in quills, usually single, sometimes double, very rarely more than double, from 30 to 60 cm. long, 2 to 5 cm. wide, and 0.2 to 3 mm. thick. In some instances the bark is rolled very much upon itself, in others is not even completely quilled, forming segments more or less extensive of a hollow cylinder. It is of a redder or darker color than the finest Ceylon cinnamon, thicker, rougher, denser, and breaks with a shorter fracture. It has a stronger, more pungent and astringent but less sweet and grateful taste, and though of a similar odor, is less agreeably fragrant. It is the kind almost universally kept in our shops. Of a similar character is the cinnamon imported directly from various parts of the East Indies. But under the name of cassia have also been brought to us very inferior kinds of cinnamon, collected from the trunks or large branches of the trees, or injured by want of care in keeping, or perhaps derived from inferior species. It is said that cinnamon from which the oil has been distilled is sometimes fraudulently mixed with the genuine. These inferior kinds are detected, independently of their greater thickness and coarseness of fracture, by their deficiency in the peculiar sensible properties of the spice. Chinese cinnamon is "in quills of varying length and about 1 mm. or more in thickness; nearly deprived of the corky layer; yellowish-brown; outer surface somewhat rough; fracture nearly smooth; odor fragrant; taste sweet, and warmly aromatic." *U. S.* 1890. Cassia is no longer official in the U. S. P., it having been dropped at the 8th Revision.

Powdered cinnamon is often grossly adulterated with sugar, ground walnut shells, galanga rhizome and various other substances. Galanga, according to Schmitz-Dumont, may be detected by the presence of small club-shaped, rod-shaped, partly bent, microscopic pieces of resinotannol. (*Zeit. oeff. Chem.,* 1903, No. 2.) Powdered cassia buds are frequently added to the inferior cinnamon powders, but can hardly be looked upon as an adulterant, as they contain a larger proportion of volatile oil than the lower grades of cinnamon.

The *Pharmacographia* gives the following tests for distinguishing powdered cassia from powdered cinnamon, and for recognizing the inferior varieties of cassia. Make a decoction of powdered cinnamon of known genuineness, and one of similar strength of the suspected powder; when cool and strained, test a fluidounce of each with one or two drops of tincture of iodine. A decoction of cinnamon is but little affected, but in that of cassia a deep blue-black tint is immediately produced. The cheap kinds of cassia known as *cassia vera* may be distinguished from the more valuable Chinese cassia as well as from cinnamon by their richness in mucilage; this can be extracted by cold water; it is a thick glairy liquid, giving dense ropy precipitates with corrosive sublimate or neutral lead acetate, but not with alcohol.

Microscopic Structure.—Ceylon cinnamon usually consists simply of the inner bark, the outer coatings having been stripped off during its preparation for market. Three layers are distinguishable in the liber. "1. The external surface, which is composed of one to three rows of large thick-walled cells, forming a coherent ring; it is only interrupted by bundles of bast fibres, which are obvious even to the unaided eye. 2. The middle layer is built up of about 10 rows of parenchymatous thin-walled cells, interrupted by much larger cells containing deposits of mucilage, while other cells not larger than those of the parenchyma itself are filled with essential oil. 3. The innermost layer exhibits the same thin-walled but smaller cells, yet inter-

sected by narrow somewhat darker medullary rays, and likewise interrupted by cells containing either mucilage or essential oil, instead of bundles of bast fibres. Fibres mostly isolated are scattered through the two inner layers, the parenchyma of which abounds in small starch granules accompanied by tannic and on a longitudinal section the length of the liber fibres becomes more evident, as well as the oil-cells and mucilage cells." (*Pharmacographia.*)

The coarser cassia bark, or *cassia lignea,* usually has some of the external or corky layer adherent to it, and always the parenchymatous mesophlœum or middle bark, but the inner bark constitutes the chief mass. Isolated bast fibers and thick-walled stone cells are scattered even through the outer layers of a transverse section. In the middle zone they are numerous, but do not form a coherent sclerenchymatous ring as in Ceylon cinnamon. The innermost part of the bast shares the structural character of cinnamon, with differences due to age, as, for instance, the greater development of the medullary rays. Oil cells and mucilage cells are likewise distributed among the parenchyma of the former. The finest cassia or Chinese cinnamon has the three layers described in Ceylon cinnamon, but is distinguished by the adherent outer parenchymatous and suberous layer. For an excellent description of the microscopical structure of the commercial cinnamon see Winton and Moeller, "*The Microscopy of Vegetable Foods.*" Spaeth gives the microscopical characteristics of the several kinds of cinnamon, discusses the adulterants of powdered cinnamon and the means of detection in *Ph. Centralh.*, 1908, pp. 724, 729. Rosenthaler and Reis give an excellent pharmacognostical study of Seychelles Cinnamon in *Ber. d. pharm. Gesellsch.*, Berl., 1909, p. 490.

Chemical Composition.—According to the analysis of Vauquelin, cinnamon contains a peculiar volatile oil, tannin, mucilage, a coloring matter, an acid, and lignin. The tannin is of the variety which yields a greenish-black precipitate with the salts of iron. Thos. R. Thornton (*A. J. P.*, 1895, 400) has examined the tannin of *C. Cassia.* He found it to amount to about 3.90 per cent., as an average of three different determinations on different samples. He found it impossible to extract the tannin by any one of several methods tried, and concludes that it either has the phlobophene (anhydride) character as it exists in the drug or acquires such character when brought into contact with water. Jas. A. Ferguson (1887), in the laboratory of the Philadelphia College of Pharmacy, determined the ash of several samples of Ceylon cinnamon, finding an average of 4 per cent., while in powdered *cassia cinnamon* he found 2.8 and 2.5 per cent. (*A. J. P.*, 1887, 278, 279.) The oil obtained from the Cayenne cinnamon was found to be more biting than that from the Ceylon. Bucholz found in 100 parts of *cassia lignea* 0.8 of volatile oil, 4.0 of resin, 14.6 of gummy extractive (probably including tannin), 64.3 of lignin and bassorin, and 16.3 of water, including loss.

This aromatic yields its virtues wholly to alcohol, and less readily to water. At the temperature of boiling alcohol very little of the oil rises, and an extract prepared from the tincture retains, therefore, the aromatic properties. For an account of the volatile oil, see *Oleum Cinnamomi.*

Uses.—Cinnamon is among the most grateful and efficient of the aromatics. It is warm and cordial to the stomach, carminative, distinctly astringent, and, like most other substances of this class, more powerful as a local than as a general stimulant. It is seldom prescribed alone, though, when given in powder or infusion, it will sometimes allay *nausea,* check *vomiting,* and relieve *flatulence.* It is chiefly used as an adjuvant, and enters into a great number of official preparations. It is often employed in *diarrhea,* in connection with chalk and astringents.

Dose, of powder, ten to twenty grains (0.65 to 1.3 Gm.).

COCAINA. U. S., Br.

COCAINE Cocain.

(cō-cą-ĭ'ną)

"An alkaloid [$C_{17}H_{21}O_4N$ or $C_6H_{11}(C_6H_5CO)ON.COOCH_3$=303.18] obtained from *Erythroxylon Coca* Lamarck and its varieties (Fam. *Erythroxylaceæ*). Preserve it in well-closed containers protected from light." *U. S.* "Cocaine, $C_{17}H_{21}NO_4$, is an alkaloid obtained from the leaves of Erythroxylum Coca, *Lam.*, and its varieties." *Br.*

Benzoyl-ecgonine-methyl-ester; Benzoyl-methyl-ecgonine Cocainum; Cocaïne, *Fr. Cod.;* Cocain, Kokain, *G.*

Owing to the small yield, it is found more profitable to manufacture cocaine in South America and export it, thus saving the expense of transporting the bulky coca leaves.

Properties.—It is officially described as in "large, colorless, four-sided, or six-sided monoclinic prisms, or as a white crystalline powder; odorless. One Gm. of Cocaine dissolves in about 600 mils of water, 6.5 mils of alcohol, 0.7 mil of chloroform, 3.5 mils of ether and in 12 mils of olive oil at 25° C. (77° F.), also in

270 mils of water at 80° C. (176° F.); very soluble in warm alcohol; slightly soluble in liquid petrolatum. It melts between 96° and 98° C. (204.8° and 208.4° F.). On neutralizing carefully an alcoholic solution of Cocaine with diluted hydrochloric acid and evaporating the solution to dryness, the residue responds to the tests for identity and purity under *Cocainæ Hydrochloridum.*" *U. S.*

The British Pharmacopœia gives the following description and tests: "In colorless monoclinic prisms. No odor; taste bitter, followed by a sensation of tingling and numbness. Soluble in 10 parts of *alcohol* (90 per cent.), in 4 parts of *ether,* in 0.5 part of *chloroform,* and in 24 parts of *olive oil;* almost insoluble in *water.* Melting point 98° C. (208.4° F.). The dry salt obtained by dissolving Cocaine in *water* acidified with *hydrochloric acid,* and evaporating the solution, responds to the tests described under 'Cocainæ Hydrochloridum.'" *Br.*

The following was Niemann's process for making cocaine: The leaves were exhausted with 85 per cent. alcohol acidulated with 2 per cent. of sulphuric acid; the tincture was treated with milk of lime and filtered; the filtrate was neutralized with sulphuric acid, and the alcohol distilled off. The syrupy residue was treated with water to separate resin, and then precipitated by sodium carbonate. The deposited matter was exhausted by ether, and the ethereal solution, after most of the ether had been distilled, was allowed to evaporate spontaneously. The cocaine was thus obtained in colorless crystals, mixed with a yellowish-brown matter of a disagreeable odor, which was separated by washing with cold alcohol. E. R. Squibb's process for cocaine and its hydrochloride is as follows: Coarsely ground coca leaves are repercolated with an aqueous five per cent. solution of sulphuric acid, and a very dense, slightly acid percolate is obtained; this is thoroughly agitated with pure coal oil and an excess of sodium carbonate; the liberated alkaloid is retained by the coal oil, and is nearly free from coloring matter; the oily solution is then agitated with acidulated water, and again precipitated by sodium carbonate in the presence of ether. The ethereal solution of cocaine is treated with diluted hydrochloric acid fractionally, and the nearly colorless solutions of cocaine hydrochloride are cautiously evaporated in shallow porcelain pans almost to dryness. The product is in the form of a white, crystalline, granular powder, and is a nearly pure anhydrous salt. (*Ephem.,* 1887, 906.) For Henrique's process see *Proc. A. Ph. A.,* 1895, 999. Pure cocaine is in colorless, transparent prisms, inodorous, of a bitterish taste, soluble in 704 parts of cold water, more soluble in alcohol, and freely so in ether. The solution has an alkaline reaction and a bitterish taste, leaving a peculiar numbness on the tongue. The alkaloid melts at 98° C. (208.4° F.), and on cooling congeals into a transparent mass, which gradually becomes crystalline. Heated above this point it changes color, and is decomposed. It is inflammable, burning with a bright flame, and leaving charcoal. With the acids it forms soluble and crystallizable salts, which are more bitter than the alkaloid itself. The formula is $C_{17}H_{21}NO_4$. (See *Cocainæ Hydrochloridum,* p. 361.) Niemann also obtained wax, a variety of tannic acid (*cocatannic acid*), and a concrete volatile odorous substance. The presence of *hygrine* in coca leaves is not confirmed. A considerable number of closely allied alkaloids, all of which appear to be derivatives of ecgonine, are found in the leaves of *Erythroxylon Coca.* The following list is given in Allen (*Com. Org. Anal.,* 2d ed., vol. iii, Part II, 271), on the authority of Paul and Cownley:

$C_9H_{13}NO_2$, *Anhydro-ecgonine.*
$C_9H_{15}NO_3$, *Ecgonine.*
$C_{16}H_{19}NO_4$, *Benzoyl-ecgonine.*
$C_{17}H_{21}NO_4$, *Benzoyl-ecgonine methyl ester* (*cocaine*).
$C_{18}H_{21}NO_4$, *Cinnamyl-ecgonine.*
$C_{19}H_{23}NO_4$, *Cinnamyl-ecgonine methyl ester.*
$C_{38}H_{46}N_2O_8$, *Cocayl-ecgonine methyl ester* (*cocamine*).
$C_{40}H_{50}N_2O_8$, *Homo-cocamine.*
$C_{17}H_{19}NO_2$, *Benzoyl-pseudotropine* (*tropacocaine*).

With the exception of ecgonine and anhydroecgonine, all of the bodies in the foregoing list are saponifiable, splitting up when heated to from 80° to 100° C. (176°–212° F.) with hydrochloric acid, or when boiled with alcoholic potassium hydroxide.

As the separation of cocaine from the accompanying alkaloids and products of hydrolysis is difficult, Liebermann (*Ber. d. Chem. Ges.,* xxi, 3196) has proposed a synthetic method which avoids these difficulties and at the same time utilizes the amorphous by-products. The mixed bases are boiled with hydrochloric acid, whereby they all suffer hydrolysis with formation of ecgonine; then, by passing dry hydrochloric acid into a solution of ecgonine hydrochloride in methyl alcohol, the hydrochloride of ecgonine methyl ester is formed, which on concentrating the alcoholic solution crystallizes out in prisms. Cocaine is formed when this compound is heated on the water bath with an equal weight of benzoyl chloride until the mixture becomes homogeneous and the evolution of hydrochloric acid ceases. The melted mass is poured into water and separated from the insoluble benzoic acid, when the cocaine is precipitated by ammonia and recrystallized from alcohol. Hesse investigated addition products of ecgonine and produced a crystalline compound of ecgonine and methyl iodide, $C_9H_{15}NO_3$, $CH_3I + H_2O$, and a methyl chloride compound, $C_9H_{15}NO_3,CH_3Cl + H_2O$. (*P. J.,* 1902, 275.) He also extracted four definite compounds, not alkaloids, from the leaves of coca obtained from Java. These bodies are 1. *Cocacitrin,* $C_{23}H_{32}O_{17}$, a yellow crystalline compound with three molecules of water, melting at 186° C. (366.8° F.). This appears to be a glucoside,

yielding a sugar, *cocaose,* which may be identical with *dextrotalose,* since its *osazone* melts at 180° C. (356° F.). 2. *Cocaeetin,* $C_{16}H_{12}O_7$, forming yellow needles with three molecules of water of crystallization. This melts at 260° to 265° C. (500°–509° F.). 3. *Cocaflavin,* $C_{34}H_{38}O_{19}$, which forms yellow crystals with four molecules of water. It yields dextrose and galactose on hydrolysis with diluted sulphuric acid, and is, therefore, probably a glucoside. 4. *Cocaflavetin,* containing two methoxy groups, forms greenish-yellow needles with three molecules of water and melts at 230° C. (446° F.). (*P. J.,* April, 1903, 585.) The tannin of coca leaves strikes a green-black with ferric salts, and has received the name of *cocatannic acid.* Romburgh detected traces of *methyl salicylate* in the distillate from coca. (*Chem. Ztg.,* 1895, 130.)

Uses.—(See p. 362.) For ordinary purposes cocaine hydrochloride is almost universally preferred, other salts of cocaine, however, have been used in medicine. *Cocaine borate* has been recommended for ophthalmological uses. *Cocaine hydriodide* which occurs in colorless crystals moderately soluble in water, has been recommended by R. Marcus as being especially suitable for use by cataphoresis for the production of anesthesia. For medicinal uses, see *Cocaine Hydrochloride.*

Dose, one-eighth to one-fourth grain (0.008–0.016 Gm.).

COCAINÆ HYDROCHLORIDUM. U. S., Br.

COCAINE HYDROCHLORIDE Cocain. Hydrochl. [Cocainæ Hydrochloras, U. S. 1890, Cocaine Hydrochlorate, Cocaine Chloride, Cocainum Hydrochloricum P. I.]

(cō-cą-ī′næ hȳ-drǫ-ȼhlō′rį-dūm)

"The hydrochloride [$C_{17}H_{21}O_4N.HCl$ = 339.65] of the alkaloid cocaine." *U. S.* "Cocaine Hydrochloride, $C_{17}H_{21}NO_4,HCl$, is the hydrochloride of the alkaloid cocaine." *Br.*

Hydrochlorate of Cocaine; Chlorhydrate de Cocaine, *Fr. Cod.;* Cocainum hydrochloricum, *P. G.;* Cocainhydrochlorid, *G.;* Cloridrato di cocaina, *It.*

Preparation.—Cocaine hydrochloride may be made "by agitating with ether an aqueous solution of an acidulated alcoholic extract of coca made alkaline with sodium carbonate; separating and evaporating the ethereal liquid; purifying the product by repeating the treatment with acidulated water, sodium carbonate, and ether; decolorizing; neutralizing with hydrochloric acid, and recrystallizing." *Br.* 1885. It is also made by dissolving cocaine in ether or petroleum benzin, and passing dry hydrochloric acid gas into the solution, when the hydrochloride will separate, this may then be dissolved in alcohol and recrystallized.

Properties.—It is officially described as: "Cocaine Hydrochloride occurs in colorless, transparent, monoclinic prisms; in flaky, lustrous leaflets or as a white, crystalline powder; odorless; permanent in the air. One Gm. of Cocaine Hydrochloride dissolves in 0.4 mil of water, 3.2 mils of alcohol, and in 12.5 mils of chloroform at 25° C. (77° F.); also in 2 mils of alcohol at 60° C. (140° F.); soluble in glycerin, insoluble in ether. An aqueous solution of the salt (1 in 20) is neutral to litmus and is lævorotatory. It melts between 183° and 191° C. (361.4° and 375.8° F.), the higher melting point indicating greater purity. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 100), a white precipitate insoluble in nitric acid. Add 5 drops of a solution of chromium trioxide (1 in 20) to 5 mils of a solution of Cocaine Hydrochloride (1 in 50); a yellow precipitate is produced which redissolves on shaking the mixture; on now adding 1 mil of hydrochloric acid, a permanent, orange-colored, crystalline precipitate is formed. Dissolve about 0.1 Gm. of the salt in 1 mil of sulphuric acid; not more than a slight yellow tint is produced (*readily carbonizable impurities*). Keep this solution at a temperature of 100° C. (212° F.) for five minutes, then cautiously mix it with 2 mils of distilled water; the aromatic odor of methyl benzoate is noticeable and, on cooling, crystals of benzoic acid form, which dissolve on the careful addition of alcohol. A solution of about 0.01 Gm. of Cocaine Hydrochloride in 1 mil of distilled water yields, on the addition of 2 mils of tenth-normal potassium permanganate V.S., a violet, crystalline precipitate which appears brownish-violet when collected on a filter, and shows characteristic, crystalline aggregates under a low power microscope. Incinerate 0.5 Gm. of Cocaine Hydrochloride; no weighable ash remains. Mix 5 mils of an aqueous solution of the salt (1 in 50) with 0.3 mil of normal sulphuric acid V.S. and 0.1 mil of tenth-normal potassium permanganate V.S.; a violet tint is produced which does not disappear entirely within half an hour (*cinnamyl-cocaine*). Dilute 5 mils of an aqueous solution of the salt (1 in 50), in a beaker, with distilled water to make 85 mils, add 0.2 mil of ammonia water and stir the solution vigorously during five minutes, with occasional rubbing of the sides of the beaker with a stirring rod. A crystalline precipitate of cocaine is formed and the supernatant liquid is clear (*isatropyl-cocaine*). The presence of 0.5 per cent. of isatropyl-cocaine will prevent the formation of nearly all of the precipitate, and will cause the supernatant liquid to be milky." *U. S.*

"In colorless prismatic crystals, or a crystalline powder. No odor; taste bitter, followed by a sensation of tingling and numbness. Soluble in 0.5 part of *water,* and in 3 parts of *alcohol* (90 per cent.); insoluble in *olive oil.* Melting point 182° to 186° C. (359.6°–366.8° F.). Yields the *reactions* characteristic of chlorides. An aqueous solution is neutral to *litmus,* and when applied to the eye dilates the pupil. When moistened with *nitric acid,* the mixture evaporated to dryness, and 1 millilitre of *alcoholic solution of potassium hydroxide* added, a characteristic odor is evolved, recalling pepper-

mint. The addition of 3 drops of *N/10 solution of potassium permanganate* to a solution of 0.1 gramme of the salt in 5 millilitres of *water* to which 3 drops of *diluted sulphuric acid* have been added, gives a violet color, which, if dust is excluded, does not fade in half an hour (absence of cinnamyl-cocaine and certain other coca alkaloids). If 0.1 gramme is dissolved in 100 millilitres of water in a glass beaker, 0.25 millilitre of *solution of ammonia* stirred in, and the mixture set aside for fifteen minutes, the sides of the beaker being occasionally and not too vigorously rubbed with a glass rod, a crystalline deposit separates, leaving the supernatant liquid clear (limit of amorphous alkaloid). 0.05 gramme dissolves in 1 millilitre of cold *sulphuric acid* or cold *nitric acid* without coloration, but with hot *sulphuric acid* the salt chars, evolving an agreeable odor and yielding a sublimate of benzoic acid. Loses not more than 1 per cent. of its weight when dried at 100° C. (212° F.). No appreciable ash." *Br.*

D. Scherbatschew recommends for differentiating cocaine and several of its commoner substitutes placing three drops of the aqueous solution of the suspected substance on a glass slide and adding one drop, respectively, of each of the following reagents: (1) Ten per cent. solution of NH_3. (2) Ten per cent. solution of KOH. (3) A saturated solution of $NaHCO_3$. Stovaine and holocaine give precipitates with all three reagents; betaeucaine gives only a slight precipitate with KOH and none with the other two; nirvanine gives a precipitate with NH_3 and a slight one with KOH but none with $NaHCO_3$; alypine precipitates decidedly with NH_3 and KOH, but not with $NaHCO_3$; novocaine precipitates with KOH but not with the other two. Cocaine and tropacocaine are identified by Hankin's $KMnO_4$ test.

Uses.—It is necessary to distinguish clearly between the local and systemic effects of cocaine. When locally applied cocaine is a paralyzant to the peripheral ends of the sensory nerves, and to a lesser degree to the motor nerves, and stimulating to the muscular coats of the blood vessels. As a result of these actions when painted over mucous membranes it causes a blanching of the part and diminished sensation. It produces not only lessened sensibility to pain and touch but also of the acuity of the special senses, thus it diminishes in the mouth the power of taste and in the nose that of smell.

Systemically it is a stimulant to all parts of the central nervous system including the brain, the spinal cord, and the medulla. Its effects upon the brain are shown by an exaltation of the intellectual faculties similar to that which is produced by caffeine. In overdose it produces a delirium somewhat suggesting that of atropine to which it is chemically related. Its action upon the spinal cord is shown by increased activity of the reflexes but the convulsions which are seen in cocaine poisoning both in the lower animals and in man seem to be due to an action upon the motor area of the brain, rather than to its effect on the cord. The effects on the medullary centers are shown by an increased rapidity of the respiration and sometimes also of its depth. After toxic doses the primary stimulation is followed by a depression of the respiratory center. The blood pressure is elevated chiefly through an action upon the vasomotor center, although there is some evidence that it also stimulates the heart. Concerning the changes in the pulse rate there is difference of opinion. According to Reichert (*P. M. J.*, 1902) small doses slow the pulse rate by stimulating the cardio-inhibitory center, moderate quantities increase the rate by depressing the inhibitory mechanism, while after large toxic doses there may be a second slowing of the heart through depression of its motor ganglia. Cocaine in moderate quantities also stimulates both the voluntary and involuntary muscle fibers. It appears also to have some effect upon the nutritive processes since it causes a marked rise in the bodily temperature. Whether this increase in temperature is due to a direct action upon the thermogenic centers or is simply the result of muscular activity, is as yet not definitely settled. When instilled into the eye it causes dilatation of the pupil, usually without paralysis of accommodation. The widening of the pupil seems to be the result of an action upon the peripheral ends of the sympathetic nerve and can be further increased by the instillation of atropine.

Cocaine is used in medicine both as a local and a systemic remedy. Internally it is of value as a circulatory and respiratory stimulant and is occasionally of use as a cerebral stimulant or as a tonic. Its employment, however, in any condition which requires prolonged administration of the drug is fraught with so great danger of formation of a habit that it is rarely justifiable. In *narcotic poisonings* the simultaneous stimulation of the respiration, circulation, and cerebrum makes it a remedy of particular value.

The most important use of cocaine is as a local application to mucous membranes either for the purpose of contracting the blood vessels or lessening sensation. For the former reason it is useful to relieve congestions such as *hay fever, coryza,* or *laryngitis,* and to control or prevent *hemorrhage* from the nose and throat. There are two great drawbacks to cocaine in this use, the first that the primary contraction of the blood vessels is liable to be followed by a reactive relaxation, and the second is the ever present peril of habit-formation. As a local anesthetic it is useful in operations on the eye, nose, throat, etc., in painful *hemorrhoids, fissure in ano, vomiting, gastralgia,* and other painful diseases of the mucous membranes. While cocaine passes through all mucous membranes with greater or less ease, the unbroken skin offers a practically impassable barrier. Nevertheless, the drug is often used as a local anesthetic, especially for operative purposes, in all parts of the body. To obtain its action it is

necessary that the drug be introduced beneath the skin in some manner; it may be either simply injected hypodermically or introduced into the vicinity of the large nerve trunks, or even injected into the spinal canal. The methods of using cocaine as a local anesthetic are too numerous and complex for consideration in this work and the reader is referred to treatises on Surgery. There is a widespread belief among both pharmacists and physicians that solutions of cocaine cannot be sterilized by heat without danger of decomposition, but a number of chemists have shown that if the solution is not allowed to become alkaline the degree of hydrolysis is insignificant.

Cocaine is also useful for the purpose of dilating the pupil, where paralysis of accommodation is not desired, as for example in ophthalmoscopy.

For local application to mucous membranes an aqueous solution of one of the salts of cocaine, ordinarily the hydrochloride, is usually preferred; Gross, however (*A. E. P. P.*, 1910, lxiii, p. 80) presents evidence that the basic cocaine is a much more powerful anesthetic than its salt and some authorities give preference to oily solutions of basic cocaine.

Toxicology.—As has been pointed out by Kamenzove (*A. I. P. T.*, 1911, xxi, p. 5) there are two distinct types of cocaine poisoning, one characterized by circulatory failure and the other by neurotoxic symptoms. The first type is usually seen after relatively small doses of the drug in persons who possess an idiosyncrasy against it. The prominent symptoms are pallor of the face, vertigo, nausea, failure of the pulse, and usually more or less complete loss of consciousness. The treatment of this type of poisoning is to place the patient in a horizontal position, give rapidly acting stimulants such as hypodermic injections of ammonia or camphor. If the theory of Kamenzove that these symptoms are due to arterial spasm causing anemia of the brain is correct, then the use of amyl nitrite or nitroglycerin would be a rational procedure. The other group of cocaine poisonings is characterized by delirium, increased reflexes, more or less violent convulsions, the pulse usually being rapid and fairly strong but later may become weak, and syncope and cyanosis may intervene. The delirium is frequently associated with hallucinations and at times the patient may develop a violent mania of even homicidal character, as in a case reported by Mattison. In this type of poisoning morphine may be used cautiously to quiet the delirium and chloral or chloroform to quiet the convulsions, and stimulants as indicated. As the cocaine rarely enters the system through the alimentary canal, emptying the stomach and the use of chemical antidotes is generally not indicated.

The habitual use of cocaine as a narcotic stimulant seems to be approaching an extent of sociological importance. In the United States the conditions under which it may be prescribed or dispensed are strictly limited both by Federal, and in many states, by state laws. Koch (*Midland Druggist*, 1911, xlv, p. 211) estimates that there is 130,000 ounces of cocaine used annually by its victims. The cocaine habit is not only one of the most seductive but also one of the most rapidly injurious and difficult of eradication of all drug habits. The characteristic symptoms are changes in the mental and moral qualities, especially characterized by alternate periods of exaltation and depression, loss of appetite and of weight, peculiar pallor of the skin, insomnia, and general failure of health. A symptom which is seen in many cases and is said to be characteristic of chronic cocaine poisoning, is a sensory hallucination, as of some foreign body under the skin or of insects crawling over the person.

Dose, of the salts of cocaine, from one-fourth to one-half grain (0.016–0.03 Gm.).

COCHINEAL

(cŏc′cŭs)

"The dried female of the insect *Coccus cacti* Linné (Fam. *Coccidæ*), enclosing the young larvæ." *U. S.* "Cochineal is the dried fecundated insect, Coccus cacti, *Linn.*" *Br.*

Coccionella; Cochenille, *Fr. Cod.;* Scharlachwurm, *G.;* Cochinilla, *Sp.*

The Cochineal insect is indigenous to Mexico and Central America and in general appearance resembles a wood louse. It is usually found growing upon certain flat-stemmed forms of the Cactus family, chiefly species of Nopalea. The red dye found in the remains of the female insect has been long esteemed by the old races in these sub-tropical countries. Indeed, not only did they appreciate its value, but in order to increase the supplies, the cacti with the insects were successfully cultivated many years before even Cortez landed in Mexico in the early part of the sixteenth century.

The cochineal insect belongs to the order *Hemipteræ*, suborder *Homoptera*, family *Coccidæ*. The latter includes the scale-like insects which are characterized by the fact that the wingless female dies shortly after producing her eggs, the latter being covered up by her dead scale-like body. In the case of the cochineal insect the larvæ are found, as will be shown later on, within her inflated body. In the group of the *Coccidæ* we find a number of interesting scale insects. Here we find the lac insect from which stick-lac of commerce is produced, the latter being a resinous substance excreted by a species of *Coccus* (*Carteria*) *lacca* which inhabit the branches of several tropical trees. From the bodies of these insects also certain coloring agents known as "lac dyes" are produced. China wax, the excretion of an

insect known as "Pela" (*Ericerus pela*) is also the product of a scale insect belonging to this family. Comstock states that there are many species of the *Coccidæ* which excrete wax in considerable quantity.

The cochineal insect was first described by Hernandez in 1651. It is ordinarily in scientific works referred to as *Coccus Cacti* Linné. In the eighth edition of the U. S. Pharmacopœia the name was changed to *Pseudococcus Cacti* (Linné) Burmeister. In a "Catalogue of The Coccidæ of the World," Maria E. Fernaldo gives preference to the name *Dactylopius Coccus* Costa. In Pharmacopœial work we are justified, however, in using the Latin title that has been given precedent by usage, namely *Coccus Cacti*, as otherwise we might change the name with each revision as our knowledge of these insects is extended.

The cochineal insect feeds upon various species of the *Cactaceæ*, more especially the Nopal plant, *Nopalea* (*Opuntia*) *coccinellifera* (Mill.) S.-Dyck, a native of Mexico and Peru. It has spread into other parts of South and Central America and has been introduced into the West Indies, East Indies, Canary Islands, Southern Spain, Algeria, and is said to be found in Florida and California.

The cultivation of cochineal is rather simple in a tropical climate, all that is necessary is to have the cochineal insects and the proper cacti. Senor Santiago da Cruz e Goncalves, a surgeon established in Teneriffe over seventy years ago, and who was appointed by the Spanish Government to superintend the cultivation of cochineal in that island, wrote an interesting article on "The Cultivation of Cochineal." This was translated with some additional notes by G. J. de Nobrega in the *P. J.*, 1848–9, pp. 342–348. Roxburgh has described the cochineal culture in India (*A. J. P.*, 1842, p. 137) and C. J. Sage the cultivation in the Canary Islands, from which most of our commercial supplies are now obtained. Probably the most complete work on the distribution and cultivation of the cochineal insect is by de Ruuscher which was translated into German by Mylius in 1751 and is included in his work entitled "Physikalische Belustigungen." In speaking of the culture of cochineal insects he says, all that is necessary is for one to raise small nests upon potted Nopal plants growing in the house. Then when they are ready to propagate, the insects are transferred to the Nopal plants growing in the fields. In a few days the female lays her eggs, dying shortly thereafter. The young develop under the mother and when mature they creep up the Nopal stems seeking always the juiciest and greenest parts. Recently there has been published by Leon Diquet an article on "The History of The Cochineal Insect of Mexico," and which contains a number of illustrations of the Nopal plantations as well as very much information concerning the cultivation of cochineal in that country.

Kraemer has written an extended monograph on the nature and structure of cochineal (*A. J. P.*, 1913, p. 444), and gives the following facts concerning the life history of the cochineal insect. The female insect is without wings, about 2 mm. in length and consists of from 9 to 12 segments. It is somewhat globular, becoming later distinctly ovoid. In general appearance, as it creeps over the cactus stems, it is convex on the upper, that is the dorsal surface, and somewhat flattened or concave below, that is, on the ventral surface. It is covered with glaucous dust being a coat of wax. This wax is a protective secretion and is formed as a glandular secretion by the "wax pores" and wax hairs, the anatomy of which has been worked out by Mayer. The antennæ are rather short, consisting of 8 parts. The threadlike beak or proboscis, forming a sucking apparatus, is very fully developed. There are 3 pairs of legs which in the commercial article do not show more than 3 joints. Projecting from the posterior portion of the abdomen there are 2 short hairs or bristles, which are wanting in the commercial article.

The male is more elongated and ellipsoidal in outline and is provided with 2 transparent wings which reach beyond the extremity of the abdomen and cross each other longitudinally on the back. The head is distinguished from that of the female in being furnished with a rudimentary beak and with 2 long feathery antennæ. It is said that the male insect is reproduced in large numbers; the larvæ in the commercial cochineal does not show this to be the case. As a matter of fact, actually only one male is necessary for about 300 females. Upon performing their functions the male insects die and are blown away. They are therefore never seen in the commercial article.

The female insect after fecundation grows larger as the young larvæ develop, becoming eventually about twice her original size. She meanwhile attaches herself to the surface of the stems of the cacti, her body penetrating into the upper layer of cells. The upper dorsal surface becomes more or less cartilaginous in structure and more or less convex in shape. The lower surface is drawn toward the upper surface and in this membranous cradle the larvæ are developed. It requires about eight days for the larvæ to become full grown, when they are said to resemble the parents with the exception that they are covered with a short hairy coating. In another week they attain maturity and the females of the new generation are ready to form broods in their turn. The life history of the cochineal insect is completed in about six weeks, two weeks being required for the development of the mature insect from the egg; during the next two weeks the female crawls over the fleshy stems of the cacti, the male in the meanwhile being able to fly about; then the female attaches herself to the tissues of the Nopal plants, her body becoming a membranous cradle for the larvæ of the next generation,

and after which she dies. From three to five generations of the cochineal insect may be produced in a single year. The first generation usually is richer in coloring matter and is considered the most valuable. It is estimated that from an area of about an acre of Nopal plants approximately 100 kilos of cochineal may be gathered; this would represent about 14,000,000 of the membranous cradles with larvæ, or the dried insects of commerce.

Cochineal is defined in the U. S. Pharmacopœia as follows: "Somewhat ovate in outline, convex above, concave beneath, from 3.5 to 5 mm. in length, consisting of from 9 to 12 segments; externally grayish-purple or grayish; in the shell-like, somewhat horny abdomen lie numerous larvæ less than 1 mm. in diameter; the mature larvæ with antennæ consisting of eight joints, 3 pairs of legs, the lower having from 6 to 8 segments, and a characteristic beak or rostrum composed of 4 thread-like parts which pair off into two coils. Cochineal is easily pulverizable and yields a dark red powder, with a characteristic odor and slightly bitter taste. When masticated it colors the saliva red, due to the coloring principle, carminic acid, which is soluble in water, alcohol, or alkalies and slightly soluble in ether, but insoluble in fixed or volatile oils. Alkalies change the color of solutions of Cochineal to purple, while acids change it to reddish-yellow. When Cochineal is macerated in water no insoluble powder separates. Cochineal yields not more than 6 per cent. of ash." *U. S.*

"About five millimetres long; somewhat oval in outline, flat or concave beneath, convex above, transversely wrinkled, purplish-black or purplish-grey; easily reduced to powder, which is dark-red or puce-colored. Macerated in *water*, no insoluble powder is separated. Ash not more than 6 per cent." *Br.*

As found in commerce, the finer cochineal, *grana fina* of Spanish commerce, is in irregularly circular or oval, somewhat angular grains, about one-eighth of an inch in diameter, convex on one side, concave or flat on the other, and marked with several transverse wrinkles. Two varieties of this kind of cochineal are known to the druggist, distinguished by their external appearance. One is of a reddish-gray color, formed by an intermixture of the dark color of the insect with the whiteness of a powder by which it is almost covered, and with patches of a rosy tinge irregularly interspersed. From its diversified appearance, it is called by the Spaniards *cochinilla jaspeada.* It is the variety commonly found in commerce. The other, *cochinilla renegrida,* or *grana nigra,* is dark-colored, almost black, with only a minute quantity of the whitish powder between the wrinkles. The two are distinguished in our markets by the names of *silver grains* and *black grains.* Some suppose the difference to arise from the mode of preparation, the gray cochineal consisting of the insects destroyed by a dry heat; the black, of those destroyed by hot water, which removes the external whitish powder; it is also said that cochineal is blackened by placing the insects with black sand in a bag and swinging backward and forward until some of the juice exudes. According to Faber, who derived his information from a merchant residing in the neighborhood where the cochineal is collected, the silver grains consist of the impregnated female just before she has laid her eggs; the black, of the female after the eggs have been laid and hatched. (*A. J. P.,* xviii, 47.) There is little or no difference in their quality. *Cake cochineal* is the name given to a variety of the drug produced in Argentina. A specimen examined by Stark was in flat cakes about one-fourth of an inch thick, and, under the microscope, was seen to consist chiefly of the cochineal insect, mixed with small portions of the thorns and epidermis of the cactus, in consequence of careless gathering. It is inferior for dyeing purposes to the ordinary variety. (*P. J.,* xiv, 346.) Another and much inferior variety is the *grana sylvestra,* or wild cochineal, consisting partly of very small separate insects, partly of roundish or oval masses, which exhibit, under the microscope, minute and apparently new-born insects, enclosed in a white or reddish cotton-like substance. It is scarcely known in our drug market.

Cochineal has a faint heavy odor and a bitter, slightly acidulous taste.. Its powder is of a purplish-carmine color, tingeing the saliva intensely red. According to Pelletier and Caventou, it consists of a peculiar coloring principle, a peculiar animal matter constituting the skeleton of the insect, stearin, olein, an odorous fatty acid, and various salts. Tyrosin has also been found by De la Rue, and its presence in cochineal confirmed later on by von Miller and Rohde. (*Ber. d. Chem. Ges.,* xxvi, 2660.) It was also analyzed by John, who called the coloring principle *cochinilin.* It is, however, universally known now as *carminic acid.* Hlasiwetz and Grabowski (*Ann. Ch. Ph.,* 141, 329) gave it the formula $C_{17}H_{18}O_{10}$, and considered it to be a glucoside, which was decomposed by boiling with diluted sulphuric acid into a non-fermentable sugar and *carmine red,* $C_{11}H_{12}O_7$. The incorrectness of this view has, however, been demonstrated by von Miller and Rohde (*loc. cit.*), who have shown that the purified carminic acid is a dioxymethyl-*a*-naphthoquinone of the formula $C_{12}H_{11}O_7$, or the double formula $C_{24}H_{22}O_{14}$, and that the carmine red is identical with it. Schunk and Marchlewski (*Ber. d. Chem. Ges.,* xxvii, 2979) have confirmed these results of von Miller and Rohde, and have shown that the reason that the carminic acid as freshly extracted from the cochineal gave the apparent glucoside reaction was that it is impure. They prepared the pure crystallized carminic acid, its anilide, and identified its character as a naphthoquinone derivative. (Recent writers, without modifying the formula above given, have classified carminic acid as a derivative of *hydri-*

odene, C_9H_{10}.) It shows no sharp melting point, beginning to decompose at 130° C. (266° F.). Carminic acid is of a brilliant purple-red color, unalterable in dry air, is very soluble in water, soluble in cold and more so in boiling alcohol, insoluble in ether, and without nitrogen. It is obtained by macerating cochineal in ether, and treating the residue with successive portions of boiling alcohol, which on cooling deposits a part of the carminic acid, and yields the remainder by spontaneous evaporation. It may be freed from a small proportion of adhering fatty matter by dissolving it in official alcohol and then adding an equal quantity of ether. The pure carminic acid is deposited in the course of a few days. Chlorine readily destroys the carminic acid, and nascent hydrogen reduces it to a leuco body, which again becomes red on exposure to the air. Liebermann found that the coating of the silver cochineal consisted of a peculiar wax, which he named *coccerin,* $C_{30}H_{60}(C_{31}H_{61}O_3)_2$; this is soluble in benzene, but nearly insoluble in ether. (*P. J.,* 1885, 186; from *Ber. d. Chem. Ges.*) The aqueous infusion of cochineal is of a violet-crimson color, which is brightened by the acids and deepened by the alkalies. The coloring matter is readily precipitated. The salts of zinc, bismuth, and nickel produce a lilac precipitate, and those of iron a dark purple approaching to black. The salts of tin, especially the nitrate and the chloride, precipitate the coloring matter of a brilliant scarlet, and form the basis of those splendid scarlet and crimson dyes which have rendered cochineal so valuable in the arts. With alumina the coloring matter forms the pigment called *lake.* The finest lakes are obtained by mixing the decoction of cochineal with fresh gelatinous alumina.

The pigment called *carmine* is the coloring matter of cochineal precipitated from the decoction by acids, the salts of tin, etc., or by animal gelatin, and when properly made is of the most intense and brilliant scarlet. Cochineal-carmine requires for its production a decoction of cochineal itself, and not of carminic acid, the nitrogenized matters being essential to its formation. Liebermann (*Ber. d. Chem. Ges.,* xviii, p. 1971) considers cochineal carmine to be no ordinary compound of a coloring matter with alumina, but to be an alumina albuminate of the carmine coloring matter comparable in some respects to the product from alizarin and alumina with "Turkey-red oil." (See *C. D.,* 1893, 199; *Zeit. angew. Chem.,* 1894.) J. J. Hess proved that if fatty matters found in cochineal were removed by treatment with alcohol, a much more brilliant carmine could be produced. (Dingler, *P. J.,* 235, 88; *N. R.,* 1880, 338.) The degree of coloring power in cochineal may be approximately measured by the decolorizing effect produced by solution of potassium permanganate. For a method of applying this process, the reader is referred to a paper by J. M. Merrick, of Boston, in *A. J. P.,* 1871, 263; from *Amer. Chem.,* April, 1871. The Pharmacopœias require that when cochineal is macerated in water no insoluble powder shall be separated, and that when incinerated with free access of air it shall yield not more than 6 per cent. of ash.

Cochineal has been adulterated by causing certain heavy substances, such as powdered talc, lead carbonate, and barium sulphate, by shaking in a bag or otherwise, to adhere, by means of some glutinous material, to the surface of the insects, and thus increase their weight. Cochineal yields 1.5 per cent. of ash. Five specimens of the drug have been examined, which left in their ashes respectively 8, 12, 16, 18, and 25 per cent. of the salt of barium. (*A. J. P.,* 1870, p. 220.) The fraud may be detected by the absence, under the microscope, of a woolly appearance which characterizes the white powder upon the surface of the unadulterated insect. Metallic lead, which is said frequently to exist in fine particles in the artificial coating, may be discovered by powdering the cochineal and suspending it in water, when the metal will remain behind. Grains of a substance artificially prepared to imitate the dried insect have been mixed with the genuine in France. A close inspection will serve to detect the difference. (*J. P. C.,* 3e sér., ix, 110.) Vermilion and chrome-red (lead dichromate) are said also to have been largely used in the adulteration of carmine, to the extent sometimes of 60 or even 70 per cent. (*P. J.,* 1860, p. 547.) There can be no difficulty in detecting them by the appropriate tests. Starch has been used, according to Maisch, for the same purpose in the United States, and in one specimen he found 57.14 per cent. (*A. J. P.,* xxxiii, 18.) Artificial cochineal, prepared by coloring exhausted cochineal powder with rosaniline and forming it into grains has been found in commerce. It may be recognized by the facility with which it forms a paste with water.

The importations of cochineal have diminished, owing to the gradual replacement of this dye by the newer azo colors. In 1889, 550,000 lbs. were brought into the United States; in 1902, 1903, and 1904, the importations were 140,756 lbs., 114,326 lbs., and 162,395 lbs., respectively. The reduction in price has been such that at present the production in the Canaries is said not to be remunerative.

Uses.—Cochineal is supposed by some to possess anodyne properties, but is probably useless. In pharmacy it is employed to color tinctures and tooth powders. To infants with *whooping cough,* cochineal in substance is given in the *dose* of about one-third of a grain (0.021 Gm.) three times a day. The *dose,* of a tincture (one part in ten parts of diluted alcohol), is for an adult from twenty to thirty minims (1.3–2.0 mils). In *neuralgia,* Sauter gave half a tablespoonful (7.5 mils) with asserted cure.

CODEINA. U. S., Br.

CODEINE Codein. [Methylmorphine]

(cō-dē-ī'nȧ)

"An alkaloid [$C_{18}H_{21}O_3N + H_2O$ or $C_{17}H_{18}(CH_3)O_3N + H_2O = 317.19$] obtained from opium, or prepared from morphine by methylation. Preserve it in well-closed containers protected from light." *U. S.* "Codeine, $C_{18}H_{21}NO_3,H_2O$, is an alkaloid obtained from opium or prepared from morphine." *Br.*

Codeia, Methylmorphine; Codeinum, Codéine, *Fr. Cod.*; Codein, Kodein, *G.*; Codeina, *It., Sp.*

Preparation.—*Codeine* was discovered in 1832 by Robiquet in morphine hydrochloride prepared according to the process of Gregory. It exists in opium combined like morphine with meconic acid, and is extracted along with that alkaloid in the preparation of the hydrochloride. (See *Morphina.*) When the solution of the mixed morphine and codeine hydrochlorides is treated with ammonia, the former alkaloid is precipitated, and the codeine, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them and yields the codeine in colorless crystals on spontaneous evaporation. Codeine is the methyl derivative of morphine, as shown in the formula $C_{17}H_{18}(CH_3)NO_3$. It may be formed artificially from morphine by treating this latter successively with methyl iodide and fixed alkali. (Grimaux, 1881, *J. Chem. S.*, xliv, 358.) Codeine may be made synthetically by the following process: Morphine, 285 Gm., and nitrosomethylurethane, 132 Gm., are dissolved in 1 kilo. of methyl alcohol. With the solution is mixed, constantly stirring, a solution made by mixing 50 Gm. of potassium hydroxide in 800 Gm. of methyl alcohol. When the reaction is complete, the methyl alcohol is distilled off, and codeine is extracted from the residue with benzene, from which it afterwards separates in characteristic crystals. (*C. D.*, 1898, 237.)

Properties.—Codeine occurs in "colorless, translucent, rhombic prisms, or as a crystalline powder; odorless and slightly efflorescent in warm air. One Gm. of Codeine dissolves in 120 mils of water, 2 mils of alcohol, 0.5 mil of chloroform, and in 18 mils of ether at 25° C. (77° F.); also in 1.2 mils of alcohol at 60° C. (140° F.). A saturated aqueous solution of Codeine is alkaline to litmus and is lævorotatory. Codeine, rendered anhydrous, melts between 154° and 156° C. (309.2° and 312.8° F.). When heated in an insufficient amount of water for complete solution, it melts to oily drops, which crystallize on cooling. Sulphuric acid containing 0.005 Gm. of selenous acid in each mil produces with Codeine a green color, changing rapidly to blue, then slowly back to grass-green. About 0.01 Gm. of Codeine dissolves in 5 mils of sulphuric acid (free from nitrous compounds) without showing other than a transient, pinkish tint; on the addition of a drop of ferric chloride T.S., the solution becomes blue when warmed and changes to red on the further addition of a drop of nitric acid. When dried to constant weight at 80° C. (176° F.), Codeine loses not more than 6 per cent. of its weight. No weighable ash remains on incinerating 0.5 Gm. of Codeine. Dissolve about 0.05 Gm. of potassium ferricyanide in 10 mils of distilled water, add 1 drop of ferric chloride T.S., and then 1 mil of a neutral or slightly acid aqueous solution of Codeine (1 in 100), made with the aid of sulphuric acid; no blue color is produced at once (*morphine*)." *U. S.*

"Colorless or nearly colorless crystals. Soluble in 80 parts of *water*, and in 80 parts of *solution of ammonia*, readily soluble in *alcohol* (90 per cent.), and in *chloroform*. The aqueous solution has a bitter taste and an alkaline reaction. Melting point 155° to 156° C. (311°–312.8° F.). 0.1 gramme dissolves in 1 millilitre of cold *sulphuric acid* without coloration or with the production at most of a faint pink tinge; but when the solution is gently warmed with a trace of *ammonium molybdate* or of *ferric chloride* a deep bluish-violet color is developed which, on the addition of a drop of *diluted nitric acid*, changes to scarlet and finally orange. When a little of the powdered alkaloid is sprinkled on *nitric acid* the liquid becomes yellow but not red (distinction from morphine). A saturated aqueous solution, acidified with *hydrochloric acid*, gives no blue color, but only gradually a dull green, on the addition of diluted *T. Sol. of ferric chloride* and very dilute *solution of potassium ferricyanide* (absence of morphine). A solution (1 in 50) in *water* acidified with *hydrochloric acid* yields a white precipitate with *solution of sodium hydroxide*, but not with *solution of ammonia*." *Br.*

When added in excess to boiling water, the undissolved portion melts and sinks to the bottom, having the appearance of an oil. It may be separated from morphine by a solution of potassium or sodium hydroxide, which dissolves the morphine and leaves the codeine. It has an alkaline reaction on test paper, and combines with acids to form salts, some of which are crystallizable, particularly the nitrate. Its capacity of saturation is almost identical with that of morphine. According to Robiquet, 1 part of hydrochloric acid is saturated by 7.837 of codeine, and by 7.88 of morphine. It is distinguishable, however, from the latter principle by the different form of the crystals, which are octahedral, by its solubility in boiling ether, greater solubility in water, and insolubility in alkaline solutions, and by not assuming a red color with nitric acid, or a blue one with ferric salts. Tincture of galls precipitates from its solutions a codeine tannate. Crystallized from an aqueous solution, it contains about 6 per cent. of water, which is driven off at 100° C. (212° F.). The crystals obtained from a solution in ether contain no water.

Uses.—Codeine produces in the lower animals marked convulsive symptoms, with heightened

reflexes, disturbances of the respiration and rarely tendency to coma. In man the therapeutic dose acts as an uncertain and feeble analgesic and hypnotic, and in large doses may produce marked restlessness. The symptoms of poisoning by it have been vascular excitement, exhilaration, then depression with great anxiety, nausea and vomiting, pale, cool, clammy skin, slight contraction of pupil, and sleeplessness, with slight delirium. In some cases convulsions have been present. In regard to the toxic dose, there is the greatest difference of statement by physicians. Severe poisoning has been reported from the use of four grains, but according to some practitioners five grains have had no effect, and we have frequently given codeine in doses of from six to eight grains without the production of distinct symptoms. It has been highly lauded in the treatment of *diabetes mellitus*, and cases of recovery under its use reported. In the grave form of this disorder we have seen it fail to exert any perceptible influence, but the evidence is sufficient to demand a fair trial of the remedy in any individual case. Medical practitioners often use it to quiet *cough*, to allay *intestinal pain*, and to fulfil various other of the minor narcotic indications for which opium is commonly administered. Although less efficient than morphine it has the advantage of being less constipating and less liable to habit formation. On account of its frequent contamination with morphine, care should be exercised as to the commencing dose, but no effect at all is to be expected, if the alkaloid be pure, from less than one grain (0.065 Gm.), and this dose may be rapidly increased until some symptoms are produced. It may be given in pill or in syrupy solution.

Dose, one-fourth to two grains (0.015–0.13 Gm.).

CODEINÆ PHOSPHAS. U. S., Br.

CODEINE PHOSPHATE Codein. Phos.

(cō-dē-ĭ'næ phŏs'phās)

"The phosphate [$C_{18}H_{21}O_3N.H_3PO_4 + 2H_2O$ or $C_{17}H_{18}(CH_3)O_3N.H_3PO_4 + 2H_2O = 433.27$] of the alkaloid codeine. It yields not less than 67 per cent. of anhydrous codeine ($C_{18}H_{21}O_3N$). Preserve it in well-closed containers, protected from light." *U. S.* "Codeine Phosphate, $C_{18}H_{21}NO_3,H_3PO_4,2H_2O$, is the phosphate of the alkaloid codeine." *Br.*

Phosphate de Codéine, *Fr.*; Codeinum phosphoricum, *P. G.*; Kodeinphosphat, Phosphorsaures Kodein, *G.*

This salt was official for the first time in the U. S. VIII and Br. Pharmacopœia, 1898; it has been introduced because of its easy solubility and stability; it may be made by dissolving 1 part of codeine in 1.25 parts of 25 per cent. phosphoric acid (the solution should be slightly acid in reaction); sufficient alcohol is added to precipitate the codeine phosphate. On account of its large percentage of codeine (about 70 per cent.) it is well fitted for hypodermic injections. It occurs in "fine, white, needle-shaped crystals, or as a crystalline powder; odorless and very efflorescent. One Gm. of Codeine Phosphate dissolves in 2.3 mils of water, 325 mils of alcohol, 4500 mils of chloroform, and in 1875 mils of ether at 25° C. (77° F.); also in 0.5 mil of water at 80° C. (176° F.), and in 125 mils of boiling alcohol. Its aqueous solution (1 in 20) is acid to litmus. Silver nitrate T.S. produces in an aqueous solution of the salt, previously neutralized with ammonia water, a yellow precipitate which is soluble in diluted nitric acid and in ammonia water. Separate portions of 10 mils each of an aqueous solution of Codeine Phosphate (1 in 100), acidulated with nitric acid, are not rendered turbid at once on the addition of a few drops of barium chloride T.S. (*sulphates*), or opalescent by a few drops of silver nitrate T.S. (*chlorides*).

"**Assay.**—Dissolve about 0.5 Gm. of Codeine Phosphate, accurately weighed, in 10 mils of distilled water, add 10 mils of potassium hydroxide T.S. and shake the mixture with three successive portions of 15 mils each of chloroform, or a sufficient quantity to complete the extraction. The combined chloroform solutions, carefully evaporated to dryness on a water bath, yield, after drying to a constant weight at 110° C. (230° F.), not less than 67 per cent. of anhydrous codeine. In other respects Codeine Phosphate responds to the tests of identity and purity under *Codeina*, omitting the melting point and ash test." *U. S.*

"White efflorescent crystals. Taste slightly bitter. Soluble in 3.5 parts of *water*. An aqueous solution (1 in 20) has a slightly acid reaction and yields a white precipitate with *solution of sodium hydroxide*, but not with *solution of ammonia*. Loses its water of crystallisation at 100° C. (212° F.). Yields the *reactions* characteristic of phosphates, and responds to the color-tests described under 'Codeina.'" *Br.*

Uses.—The medicinal properties of codeine phosphate are the same as those of codeine.

Dose, one-fourth to two grains (0.015–0.13 Gm.).

Off. Prep.—Syrupus Codeinæ Phosphatis, *Br.*

CODEINÆ SULPHAS. U. S.

CODEINE SULPHATE Codein. Sulph.

(cō-dē-ĭ'næ sŭl'phās)

"The sulphate [$(C_{18}H_{21}O_3N)_2.H_2SO_4 + 5H_2O$ or $(C_{17}H_{18}(CH_3)O_3N)_2.H_2SO_4 + 5H_2O = 786.52$] of the alkaloid codeine. Preserve it in well-closed containers, protected from light." *U. S.*

Codeinum sulfuricum; Sulfate de Codéine, *Fr.*; Kodein sulfat, Schwefelsaures Kodein, *G.*

Preparation.—Codeine sulphate may be made by dissolving codeine in warm water, adding sufficient sulphuric acid to neutralize, evaporating and crystallizing; 16.71 Gm. of sulphuric acid of official strength will be required to neutralize 100 Gm. of codeine.

Properties.—Codeine sulphate is officially described as in "long, glistening, white, needle-shaped crystals or rhombic prisms, or as a crystalline powder; odorless and efflorescent in the air. One Gm. of Codeine Sulphate dissolves in 30 mils of water and in 1280 mils of alcohol at 25° C. (77° F.); also in 6.5 mils of water at 80° C. (176° F.), and in 440 mils of alcohol at 60° C. (140° F.); insoluble in chloroform or ether. Its aqueous solution (1 in 40) is neutral or not more than faintly acid to litmus. Barium chloride T.S. produces, in an aqueous solution of the salt, a white precipitate which is insoluble in hydrochloric acid. When dried to constant weight at 100° C. (212° F.), Codeine Sulphate loses not more than 12 per cent. of its weight. In other respects the salt responds to the tests for identity and purity under *Codeina*, omitting the melting point." *U. S.*

Uses.—The medicinal properties of this salt are those of the alkaloid codeine.

Dose, one-fourth to two grains (0.015–0.13 Gm.).

Off. Prep.—Syrupus Codeinæ, *N. F.*

Colchicum autumnale, often called *meadow saffron*, is a perennial bulbous plant, the leaves of which appear in spring, and the flowers in autumn. Its manner of growth is peculiar, and deserves notice as connected in some measure with its medicinal efficacy. In the latter part of summer, a new bulb, or *corm*, as the part is now called, begins to form at the lateral inferior portion of the old one, which receives the young offshoot in its bosom and embraces it half round. The new plant sends out roots from its base, and is furnished with a radical spathe, which is cylindrical, tubular, cloven at top on one side, and half under ground. In September, from two to six flowers, of a lilac or pale-purple color, emerge from the spathe, unaccompanied by leaves. The corolla consists of a tube from 10 to 12 cm. long, concealed for two-thirds of its length in the ground, and of a limb divided into six segments. The flowers perish by the end of October, and the rudiments of the fruit remain under ground until the following spring, when they rise upon a stem above the surface, in the form of a three-lobed three-celled capsule. The leaves of the new plant appear at the same time, so that in fact they follow the flower instead of preceding it, as might be inferred from the order of the seasons in which they respectively show themselves. The leaves are radical, spear-shaped, erect, numerous, about 12 cm. long, and 2.5 cm. broad at the base. In the meantime, the new corm has been increasing at the expense of the old one, which, having performed its appointed office, perishes; while the former, after attaining its full growth, sends forth shoots, and in its turn decays. The old corm in its second spring, and a little before it perishes, sometimes puts forth one or more small corms, which are the sources of new plants. The usual method of propagating colchicum is by planting the bulbs about August or September in deep rich soil, about 2 or 3 inches below the surface and about 3 inches apart in the row. (*D. C.*, 1912, p. 134.)

C. autumnale is a native of the temperate parts of Europe and of Northern Africa, growing in moist pastures and meadows. Attempts have been made to introduce its culture into this country, but with no great success, though small quantities of the corm, of apparently good quality, have entered commerce. The flowers possess virtues similar to those of the corm and are recognized by the French Codex.

Colchici Cormus.—The medicinal virtue of the corm depends much upon the season at which it is collected. Early in the spring it is too young to have fully developed its peculiar properties, and late in the fall it has become exhausted by the nourishment afforded to the new plant. The proper period for its collection is from the early part of June, when it has usually attained perfection, to the middle of August, when the offset appears. It may be owing, in part, to this inequality at different seasons that entirely opposite reports have been given of its powers. Krapf ate whole corms without inconvenience; Haller found them entirely void of taste and acrimony, and we are told that in Carniola the peasants use them as food with impunity in the autumn. On the other hand, there can be no doubt of its highly irritating and poisonous nature, when fully developed, under ordinary circumstances. Perhaps soil and climate may have some influence in modifying its character.

Christison found the roots collected in April to be more bitter than those gathered in

July, and conjectures that the common opinion of their superior efficacy at the latter season may not be well founded. Schroff states, as the result of his observation, that the autumnal root is much stronger than that dug in the summer. (See *A. J. P.*, xxix, 324.)

The corm is often used in the fresh state in the countries where it grows, as it is apt to be injured in drying, unless the process is carefully conducted. The usual plan is to cut the corm, as soon as possible after it has been dug up, into thin transverse slices, which are spread out separately upon paper or perforated trays and dried with a moderate heat. The reason for drying it quickly after removal from the ground is that it otherwise begins to vegetate, and a change in its chemical nature takes place; and such is its retentiveness of life that, if not cut in slices, it is liable to undergo a partial vegetation even during the drying process. Houlton recommends that the corm be stripped of its dry coating, carefully deprived of the bud or young bulb, and then dried whole. It is owing to the high vitality of the bud that the corm is so apt to vegetate. During desiccation there is great loss of weight, 70 per cent. being the average for a number of years in the laboratory of Allen & Hanburys, in London.

The recent bulb or corm of *C. autumnale* resembles that of the tulip in shape and size, and is covered with a brown membranous coat. Internally it is solid, white and fleshy, and, when cut transversely, yields, if mature, an acrid milky juice. There is often a small lateral projection from its base, which is the bud for the development of a new plant; this bud is frequently broken off in drying. When dried, and deprived of its external membranous covering, the corm is of an ash-brown color, convex on one side, and somewhat flattened on the other, where it is marked by a deep groove extending from the base to the summit. As found in commerce, it is always in the dried state, sometimes in segments made by vertical sections of the bulb, but generally in transverse circular slices. The U. S. Pharmacopœia describes the corm as follows: "Usually in reniform, transverse or in ovate, longitudinal slices; from 2 to 5 mm. in thickness; flat surfaces whitish, slightly roughened, and of a crystalline appearance under a hand lens; epidermis thin, light brown and finely wrinkled; fracture short and mealy, odor slight; taste bitter and somewhat acrid. The powder is light brown or grayish-brown; starch grains numerous, single or 2- to 6-compound, the individual grains varying from spherical or ovoid to polygonal, and marked with a triangular or star-shaped, central cleft, the grains being from 0.003 to 0.03 mm. in diameter; tracheæ few and with spiral or scalariform thickenings; occasional fragments of epidermal cells with thin, reddish-brown walls. Colchicum Corm yields not more than 6 per cent. of ash.

"**Assay.**—Proceed as directed under *Colchici Semen*, using 15 Gm. of Colchicum Corm." *U. S.*

"Fresh corm about thirty-five millimetres long and twenty-five millimetres broad, somewhat conical, hollowed on one side where a new corm is in process of development, and rounded on the other; covered with a thin brown membranous outer coat, and an inner reddish-yellow one; internally white and solid, and when cut yielding a whitish, turbid juice of a disagreeable odor and bitter taste. Dried slices two or three millimetres thick, yellowish at their circumference, somewhat reniform in outline; firm, whitish, amylaceous; breaking readily with a short fracture. No odor; taste bitter." *Br.*

The cut surface is white and of an amylaceous aspect. Examined with the microscope, the corm is seen to be composed of large irregular cells, full of ovoid, angular, sometimes compound, starch grains, and interspersed with spiral vessels in vascular bundles. The odor of the recent corm is said to be hircine. It is diminished, but not lost, by drying. The taste is bitter, hot, and acrid.

Colchicum corm contains the alkaloid *colchicine*, $C_{22}H_{25}NO_6$, which was made official in the U. S. P.; see *Colchicina*. Colchicine is the active principle and as much as 0.4 per cent. is found in good specimens of the corm; the official requirement is that not less than 0.35 per cent. shall be present, to be determined by assay. See *Assay for Colchicum Seed*, p. 371.

A. T. Thompson states that the milky juice of fresh colchicum produces a fine blue color if rubbed with the tincture of guaiac, and that the same effect is obtained from an acetic solution of the dried corm. He considered the appearance of this color, when the slices were rubbed with a little distilled vinegar and tincture of guaiac, a proof that the drug was good and had been well dried. J. M. Maclagan has shown that this change of color is produced with the albumen, which is not affected if previously coagulated; so that the value of the test consists simply in proving that the drying has not been effected at a heat above 82.3° C. (180° F.), or the temperature at which albumen coagulates. It is probable that this color reaction is not due to the albumen itself, but to an oxidizing enzyme or oxydase which would be susceptible to the same decomposing influences as albumen. A very deep or large notch in the circumference of the slices is an unfavorable sign, as it indicates that the bulb has been somewhat exhausted in the nourishment of the offset. The decoction yields a deep blue precipitate with solution of iodine, white precipitates with lead acetate and subacetate, mercurous nitrate, and silver nitrate, and a slight precipitate with tincture of galls. The value of colchicum is best tested by its bitterness. For method of assaying colchicum, by K. Schwickerath, see *Ph. Rund.*, 1893, 282. Important improvements have been made in the assay by Bredemann. (*Ap. Ztg.*, 1903, 18, Nos. 93, 94, 95.)

Colchici Semen.—The seeds of the meadow-saffron ripen in summer, and should be col-

lected about the end of July or beginning of August. They never arrive at maturity in plants cultivated in a dry soil or in confined gardens. (Williams.) They are officially described as follows: "Ovoid or irregularly globular, more or less pointed at the hilum; from 2 to 3 mm. in diameter; when fresh, several seeds cohering; externally dark brown, finely pitted; tough and of almost bony hardness; internally whitish or light brown; nearly inodorous; taste bitter and somewhat acrid. Under the microscope, transverse sections of Colchicum seed show a seed-coat of a few more or less collapsed cells with thin reddish-brown walls; an endosperm, making up most of the seed, consisting of cells with rather thick, porous walls, the lumina containing oil globules and aleurone grains, the latter being from 0.003 to 0.015 mm. in diameter; a small embryo, the beaked portion, or caruncle, containing numerous, somewhat ovoid, ellipsoidal or polygonal starch grains, from 0.005 to 0.016 mm. in diameter. Colchicum Seed yields not more than 8 per cent. of ash." *U. S.*

"About two and a half millimetres in diameter, subglobular, slightly pointed at the hilum, rough and of a dull reddish-brown color, minutely pitted, very hard and tough. Endosperm oily; its cells with thickened walls and large pits. No odor; taste bitter and acrid." *Br.*

They are chiefly composed of a gray horny endosperm constituted of very thick-walled cells, and surrounded by a closely adherent testa. The leafless embryo is very small, and is situated close to the surface opposite the strophiole. Williams, of Ipswich, England, first brought them into notice in 1820 as superior to the corm. Schroff, however, has found that their activity is inferior to that of the dried corm dug in autumn. (*A. J. P.*, xxix, 324.) A fluidextract and tincture of the seeds are directed in the U. S. Pharmacopœia. Their dose is slightly less than that of the similar preparations made from the corm. The seeds and powder are very seldom adulterated. Judd, however, reports examining a powder which contained fully 50 per cent. of powdered fœnugreek seed. (*Bull. A. Ph. A.*, 1909, p. 193.)

The U. S. Pharmacopœia IX directs that colchicum seed should contain not less than 0.45 per cent. of colchicine, to be determined by the following process:

Assay of Colchicum Seed.—"Introduce 15 Gm. of Colchicum Seed, in No. 60 powder, into a 500 mil flask, and add 10 mils of solution of lead subacetate and 290 mils of distilled water. Weigh the flask and contents, and digest the mixture at from 60° to 70° C. (140°–158° F.) for three hours, with occasional agitation. Cool, add distilled water to restore the original weight and filter off 200 mils. Add 0.75 Gm. of sodium phosphate to the clear filtrate, shake the mixture frequently during half an hour, and filter off 100 mils representing 5 Gm. of Colchicum Seed. Shake out the alkaloid from the filtrate with chloroform until completely extracted, as shown by testing with iodine T.S. (in place of the usual mercuric potassium iodide T.S.), and evaporate the chloroform solution; add about 1 mil of alcohol and again evaporate. Repeat this operation once more and dry the residue to constant weight at 100° C. (212° F.). To this weighed residue contained in a flask add 5 mils of tenth-normal sulphuric acid V.S. and 5 mils of distilled water and heat the mixture for ten minutes at 70° C. (158° F.). Now filter the liquid through a pledget of purified cotton, wash the flask and cotton with distilled water, reject the filtrate and washings and remove as much of the water from the cotton as possible. Dissolve any insoluble residue that may remain on the cotton by washing it first with a little alcohol and then with ether; collect the alcohol-ether washings in the flask, evaporate, and dry the residue to constant weight at 100° C. (212° F.). Deduct this weight from the weight of residue previously obtained. The difference will be the weight of colchicine obtained from 5 Gm. of Colchicum Seed (see Proximate Assays, Part III)." *U. S.*

Uses.—The investigations into the physiological action of colchicum have not as yet yielded a very clear explanation of its therapeutic effects. Dixon and Malden (*J. P.*, 1908, xxxviii, p. 50) have found that it is an active stimulant to the unstriped muscle, increasing intestinal and uterine contractions and bronchial tonus. After large doses it depresses the vasomotor system, causing a marked fall in the blood pressure. When injected subcutaneously in somewhat smaller doses it produces a transient decrease in the number of leukocytes followed after twenty-four hours by an enormous increase, the alterations being especially notable in the number of polymorphonuclear corpuscles. These effects appear to be the result of an action upon the bone marrow. Jackson and Blackfan (*J. A. M. A.*, 1906, xlvii) find an increased output of uric acid under its influence, but they believe this is due rather to an increased formation than a more active elimination, but Denis (*J. P. Ex. T.*, 1915, vii, 609) was unable to detect any change in the amount of uric acid either in the urine or blood.

The poisonous properties of colchicum were known to the ancients, but, while it is generally supposed that the hermodactyls were derived from some species of the genus, the use of meadow-saffron cannot be certainly traced back further than the sixteenth century. Although it has from time to time been recommended for various complaints, it is used to-day only in the treatment of *gout*. There is considerable clinical evidence that full doses of colchicum administered during the acute attack of a *podagra* will often abort it. The treatment, however, is not without serious danger and most clinicians urge caution in the use of colchicum during the attack. It appears also to be of service in those more chronic conditions of disturbed metabolism known variously as uric acid diathesis or *lithemia*.

In preparing colchicum pharmaceutically, if

it be desired to retain the colchicine unchanged, both acids and alkalies should be avoided and as far as possible also heat. As pointed out below, under various conditions colchicine may be decomposed into colcheiceine, colchicinic acid, and various allied products. Whether these derivatives of colchicine possess the therapeutic virtues of the natural alkaloid is uncertain, but Fuehner (*A. E. P. P.*, 1913, lxxii, p. 228) has shown that colcheiceine is very much less toxic than colchicine.

When taken internally in therapeutic dose, colchicum usually produces no other symptoms than intestinal pains and looseness of the bowels. In some rare cases it is said to give rise to copious diuresis or diaphoresis instead of purging. When larger amounts are exhibited, the purging is more pronounced, and there may be also vomiting. With these symptoms there may be some depression, which seems to be due to the gastro-intestinal irritation rather than to the direct action of the poison. In an overdose, it may produce dangerous and even fatal effects. Excessive nausea and vomiting, abdominal pains, purging and tenesmus, great thirst, sinking of the pulse, coldness of the extremities, and general prostration, with occasional symptoms of nervous derangement, such as headache, delirium, and stupor, are among the results of its poisonous action. A peculiarity of its influence is that when its dose is increased beyond a certain point there is not a corresponding increase in the rapidity of the fatal issue. This is probably because it kills not by a direct influence upon the heart or the nervous system, but by causing gastro-enteritis. On post-mortem examination the alimentary mucous membrane is found much inflamed.

Dose, of the dried corm and seed, from two to eight grains (0.13–0.52 Gm.), which may be repeated every four or six hours until its effects are obtained.

COLCHICINA. U. S.

COLCHICINE

(cŏl-çhĭ-cĭ'nȧ)

"An alkaloid [$C_{22}H_{25}O_6N = 399.21$] obtained from colchicum. Preserve it in well-closed containers, protected from light." *U. S.*

Colchicine, *Fr.;* Colchicin, *G.*

The alkaloid *colchicine,* whose nature was first precisely made out by Geiger and Hesse, has been the subject of much controversy, for an account of which the reader is referred to the seventeenth edition of the U. S. Dispensatory, page 427, foot-note. It is now recognized to be the *methyl ester* of *acetyl-trimethyl colchicinic acid,* and has the formula $C_{22}H_{25}O_6N$. When colchicine is heated with 3 parts of hydrochloric acid for two hours on the water bath, it is decomposed, with the formation of *colchicinic acid,* $C_{18}H_{15}O_5N$, and *dimethyl colchicinic acid,* $C_{18}H_{19}O_5N$. When colchicine is boiled with water containing sulphuric acid, it is decomposed thus:

$$C_{22}H_{25}O_6N + H_2O = C_{21}H_{23}O_6N + CH_3OH$$

the products formed being *colcheiceine* and methyl alcohol. The colcheiceine is formed so readily that some of the reactions commonly attributed to colchicine itself are probably due to its decomposition product. Colcheiceine, which is *aceto-trimethyl colchicinic acid,* can also be made synthetically by heating *trimethyl colchicinic acid* with acetic anhydride to 100° C. (212° F.). Colchicine has also been built up synthetically from colcheiceine, sodium methylate, and methyl iodide, which are heated together to 100° C. (212° F.). (Johanny, *Monatshefte,* 9, 868.) It forms precipitates with the usual alkaloidal reagents.

Properties.—The U. S. Pharm. IX officially describes colchicine as in "pale yellow, amorphous scales, or as a pale yellow, amorphous powder, turning darker on exposure to light; odorless or nearly so. *Great caution must be used in tasting it and then only in very dilute solutions.* One Gm. of Colchicine dissolves in 22 mils of water, 220 mils of ether, and in 100 mils of benzene at 25° C. (77° F.); also in 21 mils of water at 80° C. (176° F.); freely soluble in alcohol or chloroform; insoluble in petroleum benzin. Its aqueous solution (1 in 30) is neutral to litmus, lævorotatory, and of a yellow color, which is intensified by the addition of mineral acids. It melts between 142° and 146° C. (287.6° and 294.8° F.). Stir about 0.001 Gm. of Colchicine with a few drops of sulphuric acid; a lemon-yellow color is produced, which, on the addition of a drop of nitric acid, changes to greenish-blue, then to red and finally to yellow. On adding an excess of potassium hydroxide T.S., the color is changed to red. The addition of 2 drops of ferric chloride T.S. to 5 mils of an aqueous solution of Colchicine (1 in 100) produces no color (*colcheiceine*), but, on heating, a brownish-red color is developed, which changes to brownish-black; 1 drop of ferric chloride T.S. added to 1 mil of an alcoholic solution of Colchicine (1 in 20) produces a garnet-red color at once. No weighable ash remains on incinerating 0.1 Gm. of Colchicine. Heat a mixture of about 0.01 Gm. of Colchicine, 2 mils of potassium hydroxide T.S., and 1 drop of aniline; no odor of phenylisocyanide develops (*chloroform*)." *U. S.*

Vanderkleed and E'we (*Proc. P. Ph. A.*, 1916, p. 279) point out that commercial samples of colchicine contain chloroform in comparatively

stable form, which might be called chloroform of crystallization. This not only interferes with the melting point determination, but inasmuch as the amount of chloroform present is sometimes over 20 per cent. it becomes a fraud as well.

Uses.—The alkaloid colchicine acts like colchicum, according to Maret and Combemale, in doses of one-twelfth of a grain (0.005 Gm.) producing violent diarrhea, with diminished urinary secretion; in doses of one thirty-second of a grain (0.002 Gm.) causing some abdominal disturbance, with increased diuresis. According to J. Sprega, three grains (0.2 Gm.), repeated in three hours, caused violent gastro-enteritis, ending in death in thirty-one hours. (*Gazz. d. Ospitali*, Oct., 1890.) *Colchicine salicylate* is a yellow amorphous powder, soluble in water, alcohol, and ether, the dose being one-hundredth of a grain (0.0006 Gm.) every four hours.

Dose, one one-hundred and fiftieth to one one-hundredth of a grain (0.0004–0.0006 Gm.).

COLLODIUM. U. S., Br.

COLLODION Collod.

(cŏl-lō′dĭ-ŭm)

Collodion, *Fr. Cod.*; Collodium, *P. G.*; Kollodium, *G.*; Collodio, *It.*; Colodion, *Sp.*

* "Pyroxylin, *forty grammes* [or 1 ounce av., 180 grains]; Ether, *seven hundred and fifty mils* [or 25 fluidounces, 173 minims]; Alcohol, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]. To make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Add the alcohol to the pyroxylin contained in a suitable bottle, shake the mixture thoroughly, then introduce the ether, and again shake the mixture until the pyroxylin is dissolved. Cork the bottle well and set it aside until the liquid becomes clear. Finally decant the clear portion from any sediment which may have deposited, and transfer it to containers which must be well closed. Keep the Collodion in a cool place remote from fire." *U. S.*

"Pyroxylin, 21 grammes; Ether, 750 millilitres; Alcohol (90 per cent), 250 millilitres. Immerse the Pyroxylin in the Alcohol; add the Ether, shake occasionally until dissolved; set aside for a few days; decant if necessary." *Br.*

Collodion is a solution of gun cotton. On account of the facility with which ether evaporates, it is the better menstruum for remedial purposes, but gun cotton will not dissolve in that liquid when quite pure, and the addition of strong alcohol is necessary. Formerly the U. S. Pharmacopœia directed that the gun cotton be prepared at the time of making the collodion, giving directions for the purpose, but at the revision of 1870 the process of the British Pharmacopœia was substantially adopted, a formula for the preparation of pyroxylin being given separately in the Pharmacopœia. A process for the preparation of pyroxylin was not introduced into the U. S. Pharmacopœia IX, but the British Pharmacopœia still retains a process. (See *Pyroxylinum*.) A change has been made, however, in directing the collodion to be decanted from the sediment. In the U. S. P., 1870, the sediment was directed to be re-incorporated with the clear collodion, and the result was the making of a tougher film. This sediment consists of undecomposed filaments of cotton, and these become partially felted as the ethereal liquid evaporates and the film is forming; this direction of the former Pharmacopœia was usually disregarded, although for many purposes the cloudy film is to be preferred.

Acetone has been used as a solvent for pyroxylin and collodion so prepared is on the market.

Properties.—"Collodion is a clear, or slightly opalescent, syrupy liquid; colorless, or slightly yellowish and having the odor of ether. It is highly inflammable. When exposed to the air in a thin layer it leaves a transparent, tenacious film. Specific gravity: 0.765 to 0.775 at 25° C. (77° F.). When mixed with an equal volume of distilled water, a viscid, stringy mass separates; the aqueous liquid is not acid to litmus.

"**Assay.**—Introduce about 10 mils of Collodion into a flask; stopper and weigh accurately, then warm it on a water bath and add 10 mils of distilled water, drop by drop, with constant stirring. Evaporate the mixture on a water bath and dry the residue to constant weight at 110° C. (230° F.). The pyroxylin so obtained corresponds to not less than 5.1 per cent. of the Collodion taken, equal to about 4 Gm. of pyroxylin in 100 mils of Collodion at 25° C. (77° F.). The pyroxylin obtained burns rapidly, with a yellow flame." *U. S.*

"A colorless, highly inflammable liquid of syrupy consistence and ethereal odor. Dries quickly upon exposure to the air, and leaves a thin transparent film, which contracts rapidly on drying and is insoluble in *water* or *alcohol* (90 per cent.)." *Br.*

When applied to a dry surface, the ether quickly evaporates, and a transparent film is left, having remarkable adhesiveness and contractility. On account of the great volatility of ether, collodion must be kept in bottles well stoppered. When insecurely kept, the liquid thickens and becomes less fit for the use of the surgeon. The thickened liquid sometimes contains acicular crystals. The addition of a mixture of 3 volumes of ether and 1 volume of alcohol will generally restore the collodion to its original condition.

Uses.—Collodion was first applied to the purposes of surgery by J. Parker Maynard, of Boston, when a student of medicine, in January, 1847, although, as pointed out by Kahlbaum, Schoenbein, the discoverer of gun cotton, suggested the surgical use of an ethereal solution in 1846. (*Nat. Drug.*, 1902, 8.) It is employed for holding together the edges of incised *wounds*, for covering *ulcers*, abraded or diseased surfaces, *chilblains, chapped nipples*, etc., with an impervious film not acted upon by water, and for encasing parts which require to be kept without relative motion. It should be remembered

that while it protects the underlying tissues from external contamination, it also prevents the escape of any toxic materials already present; to hermetically close an infected wound, as with collodion, is an invitation to blood-poisoning. It is applied brushed over the part, or by means of strips of muslin. In whatever way applied, the solvent quickly evaporates, and leaves the solid adhesive material, which is soluble neither in water nor in alcohol. The rigid film thus formed contracts with a good deal of force. This property adapts collodion for certain purposes, such as drawing together the edges of wounds, exciting pressure on buboes, etc. When, however, the surgeon desires simply to protect a surface, a flexible, non-contracting film is preferable, and the official flexible collodion should be used. Collodion has been variously medicated, and thus made the vehicle of several important medicines for external application. *Iodized collodion* has been proposed by C. Fleming, for the purpose of obtaining the specific effects of iodine in a rapid manner, especially on *tumors*. See *Collodium Iodi*, N. F., Part III. Aran has proposed a *ferruginous collodion*, made of equal parts of collodion and tincture of ferric chloride, as a remedy in *erysipelas*. A *caustic collodion* may be prepared by dissolving 4 parts of corrosive sublimate in 30 of collodion. Macke, of Sorau, has used this preparation for destroying *nævi materni*. The eschar formed is one or two lines in thickness, and separates in from three to six days, leaving but a trifling cicatrix. (For formulas in which collodion is made the vehicle of croton oil, iodoform, salicylic acid, tannin, etc., see National Formulary, Part III.) All these medicated collodions are best applied by means of a camel's-hair brush.

COLLODIUM CANTHARIDATUM. U. S. (Br.)

CANTHARIDAL COLLODION Collod. Canth.
[Blistering Collodion Vesicating Collodion]

(cŏl-lō'dĭ-ŭm cạn-thăr-ị-dā'tŭm)

Collodium Vesicans, *Br.;* Blistering Collodion; Collodium Cantharidale, s. Vesicans; Collodion vésicant (cantharidé), *Fr.;* Collodium Cantharidatum, *P. G.;* Spanischfliegen-Kollodium, Blasenziehendes Collodium, *G.*

* "Cantharides, in fine powder, *sixty grammes* [or 2 ounces av., 51 grains]; Glacial Acetic Acid, *five mils* [or 81 minims]; Flexible Collodion, *eighty-five grammes* [or 3 ounces av.]; Acetone, *a sufficient quantity,* to make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the cantharides with *fifty-five mils* of acetone, to which the glacial acetic acid has been added, and set the mixture aside in a closely-covered container for twenty-four hours. Then transfer it to a percolator and continue the percolation with acetone until the drug is practically exhausted. Reduce the percolate by distillation on a water bath, in a tared flask, to *fifteen grammes* [or 231 grains] and, when cold, dissolve this concentrated extract in *eighty-five grammes* [or 3 ounces av.] of flexible collodion. Finally allow the solution to stand for several hours, and decant the clear liquid from any sediment which may have deposited, and transfer the product to containers, which must be well-closed. Keep Cantharidal Collodion in a cool place, remote from fire." *U. S.*

"Pyroxylin, 25 *grammes;* Cochineal, in powder, 10 *grammes;* Blistering Liquid sufficient to produce 1000 *millilitres.* Shake together until the Pyroxylin is dissolved, set aside till clear, and decant the clear liquid." *Br.*

The official process differs materially from that of the U. S. P. VIII. Acetone and glacial acetic acid are used to extract the cantharidin from the powdered cantharides, by percolation instead of chloroform; the acetone is afterwards recovered by distillation, and the oily residue containing the vesicant is dissolved in the collodion. The original process of Ilisch was to exhaust, by percolation, a pound of cantharides, with a mixture consisting of a pound of ether and three ounces of acetic ether, and in two ounces of this liquid to dissolve 25 grains of gun cotton. Procter stated that it had been found more advantageous to exhaust the flies with ether, distil off the ether, and mix the oily residue with collodion already prepared of the proper consistence (*A. J. P.,* xxiv, 303); but at the present time owing to the cheapness of acetone and its advantage over the very inflammable and dangerous ether the official process is greatly preferred. In the British Pharm., 1914, cochineal is used to color the film "flesh color." Charles S. Rand (*A. J. P.,* xxii, 18) states that Ilisch's preparation, made with double the proportion of ether, vesicates equally well, and proposes the addition of about 1 per cent. of Venice turpentine, which he has found to prevent the disagreeable and sometimes painful contraction of the collodion upon drying. The preparation may be kept indefinitely, without change, in an opaque glass stoppered bottle, but on exposure to the light, the greenish coloring matter of the flies bleaches, and the liquid becomes yellowish. *Cantharidized collodion* may be made from cantharidin by dissolving four grains of cantharidin in one thousand grains of flexible collodion.

Cantharidal collodion is a convenient but uncertain epispastic. It may be applied to the surface by means of a camel's-hair brush, and after the evaporation of the ether, which takes place in less than a minute, may be reapplied if the surface should not be well covered. It produces a blister in about the same time as the ordinary cerate, and has the advantages that it is applied with greater facility, is better adapted to cover uneven surfaces, and retains its place more certainly. According to Rand, if the evaporation of the ether be restrained by a piece of oiled silk immediately after its application, it will act much more speedily.

COLLODIUM FLEXILE. U. S., Br.

FLEXIBLE COLLODION Collod. Flex.

(cŏl-lō'dĭ-ŭm flĕx'ĭ-lē)

Collodion élastique, *Fr.;* Collodium elasticum, *P. G.;* Elastiches Collodium, Kollodium, *G.;* Collodio elastico, *It.;* Colodion elastico, *Sp.*

* "Collodion, *nine hundred and fifty grammes* [or 33 ounces av., 223 grains]; Camphor, *twenty grammes* [or 308.6 grains]; Castor Oil, *thirty grammes* [or 1 ounce av., 25 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Weigh the ingredients, successively, into a tared bottle and shake the mixture until the camphor is dissolved. Keep the product in well-closed containers, in a cool place, remote from fire." *U. S.*

"Collodion, 940 *millilitres;* Canada Turpentine, 40 *grammes;* Castor Oil, 20 *grammes.* Mix." *Br.*

The contractility of the collodion film has long been felt as a drawback to its use simply for the purposes of protection. C. S. Rand proposed to obviate this by dissolving one part of gun cotton and three of Venice turpentine in twenty parts of ether. To give more flexibility to the film, Sourisseau, of Kaiserberg, suggested the addition of one part of elemi to twelve of collodion. According to Startin, of London, opacity and elasticity may be imparted at the same time by adding from half a drachm to a drachm of lard, or some similar fatty matter, previously dissolved in ether, to an ounce of collodion. The qualities of softness and elasticity may also be given by combining collodion with castor oil, in the proportion of thirty parts to two, agreeably to the plan of Guersant, who found it useful, thus modified, in *erysipelas;* and the proportion of castor oil may be increased if thought desirable. This is the method preferred by the French Codex. An elastic collodion, somewhat similar, in which, besides castor oil, Venice turpentine and white wax are ingredients, has been proposed by E. Lauras. (*P. J.*, xii, 303.) According to Cap and Garot, the most successful way for obtaining an elastic collodion is to mix two parts of glycerin with one hundred of collodion. *Glycerized collodion* is exceedingly supple, does not crack and scale off from the skin, and accommodates itself to the motions of the part. In order to imitate the color of the skin, an ethereal tincture of turmeric or saffron may be added, so as to produce the desired tint. Meller has proposed a solution of shellac in highly rectified alcohol, so as to have a gelatinous consistence, as a substitute for collodion. Of all these plans, probably that followed in the official directions is the best. Tournie recommends, in superficial *cervical adenitis* with redness, painting the part with several layers of flexible collodion every two days. (*M. T. G.*, 1874, p. 540.)

COLOCYNTHIS. U. S. (Br.)

COLOCYNTH Colocyn. [Bitter Apple, Colocynth Apple]

(cŏl-ŏ-cȳn'thĭs)

"The dried pulp of the fruit of *Citrullus Colocynthis* (Linné) Schrader (Fam. *Cucurbitaceæ*), without the presence or admixture of more than 5 per cent. of seeds or more than 2 per cent. of epicarp." *U. S.* "Colocynth Pulp is the dried pulp of the fruit of Citrullus Colocynthis, *Schrad.*, freed from seeds." *Br.*

Colocynthidis Pulpa, *Br.,* Colocynth Pulp, Bitter Gourd, Apple, or Cucumber, Poma Colocynthidis; Coloquinte, *Fr. Cod.;* Pulpe de Coloquinte, *Fr.;* Fructus Colocynthidis, *P. G.;* Coloquintenapfel, Koloquintenmark, Koloquinten, *G.;* Coloquintide, *It.;* Coloquintida, *Sp.*

Colocynth is another one of those drugs which has given a great amount of trouble to manufacturers because the definition of the U. S. Pharmacopœia, in previous revisions, simply stated that it was the "peeled dried fruit." Notwithstanding the fact that at the end of the description there was a statement that "the seeds should be separated and rejected" the powdered drug consisted frequently of the seeds as well as pulp. In order to avoid any misunderstanding the U. S. Pharmacopœia has followed the British authority and defined Colocynth as the dried pulp. As it is not commercially possible to exclude the seeds entirely, a few being imbedded in the pulp itself, the Pharmacopœia wisely allows a minimum of 5 per cent. of seeds. It is estimated that every 100 pounds of colocynth fruit will yield 30 pounds of pulp and about 70 pounds of seeds. Tunmann (*Suedd. Apoth. Zeit.*, 1907, p. 503) states that the seeds do not contain medicinally active constituents. Francis (*Proc. A. Ph. A.*, 1906, p. 336), on the other hand, says that if the seeds are first deprived of their fixed oil with benzin, dried and then extracted with 75 per cent. alcohol, the extract is almost as active as the U. S. P. product.

Citrullus Colocynthis, or *bitter cucumber,* is an annual plant, bearing considerable resemblance to the common watermelon. The stems, which are herbaceous and beset with rough hairs, trail upon the ground, or rise upon neighboring bodies, to which they attach themselves by their numerous tendrils. The leaves, which stand alternately on long petioles, are triangular, many-cleft, variously sinuated; obtuse, hairy, of a fine green color on the upper surface, rough and pale on the under. The flowers are yellow, and appear singly at the axils of the leaves. The fruit is a globular pepo, of the size of a small orange, yellow and smooth when ripe, and contains, within a hard, coriaceous rind, a white, spongy pulp, enclosing numerous ovate, compressed, white or brownish seeds.

The plant is a native of Turkey, and abounds in the islands of the Archipelago. It grows also in various parts of Africa and Asia. Burckhardt, in his travels across Nubia, found the country covered with it; Thunberg met with it at the Cape of Good Hope, and Ainslie says that it grows in many parts of Lower India, particularly in sandy places near the sea. It is said to

be cultivated in Spain, the island of Cypress, Morocco and in the neighboring countries, and even to have been collected in Japan. Colocynth from the maritime plain between the mountains of Palestine and the Mediterranean is chiefly shipped from Jaffa, and is known as *Turkish colocynth.* It is said to be of superior quality. The fruit is gathered in autumn, when it begins to become yellow, and, having been peeled, is dried quickly in a stove or in the sunshine. Thus prepared, it is imported from the Levant. Small quantities are said to be imported into England from Mogador in the form of brown, unpeeled globular gourds. The so-called *Persian colocynth* of the London markets is very small, and has apparently been compressed in a fresh state, so that the position of the seeds is perceptible through the dry pulp. The microscopic structure and the proportion of the pulp to the seed appear to be the same as in other colocynths. (*P. J.*, xvi, 107.) Colocynth has been grown in New Mexico, but, according to Sayre, the American colocynth possesses only about two-thirds the cathartic action of the Trieste variety.

Properties.—As found in commerce, colocynth is in whitish, globular berries, from 6 to 7 cm. in diameter, very light and spongy, and abounding in seeds which constitute three-fourths of their weight. The seeds are somewhat bitter, but possess little activity, and, according to Captain Lyon, are even used as food in the north of Africa. Nachtigal confirms this statement of Captain Lyon's, but with the qualification that, before being eaten, the seeds are deprived of their coating by some mechanical means, and the kernels are heated to the boiling point, then washed with cold water, dried, and powdered. Flückiger found a bitter principle in the testa, which accounts for its rejection as food, though rendering improper the rejection of the seed in preparing the extract. He found in the kernels about 45 per cent. of fixed oil and 18 per cent. of albumen. (*A. J. P.*, 1872, 538.) They should be separated and rejected, the pulpy matter only being employed. The U. S. Pharmacopœia thus describes colocynth: "Fruits, before the removal of the seeds, nearly globular, from 4 to 7 cm. in diameter, usually more or less crushed and in broken pieces, with occasional patches of the nearly smooth epicarp; yellowish-white or brownish; light, spongy; separable longitudinally when entire into three carpels, each containing, near the outer surface, the ovoid, compressed, yellowish seeds; odor slight; taste intensely bitter. The powder is yellowish-white or buff, consisting chiefly of fragments of parenchyma cells and an occasional fragment with tracheæ; very few lignified tissues of the seed-coat, showing the characteristic stone cells which are nearly isodiametric, irregular, with either straight or undulate walls that are strongly lignified and possess simple pores; globules of fixed oil and aleurone grains very few. Powdered Colocynth must be made from colocynth pulp containing not more than 5 per cent. of seeds and, upon extraction with purified petroleum benzin, yields not more than 2 per cent. of fixed oil. Colocynth yields not more than 15 per cent. of ash." *U. S.*

"White, spongy, light fragments. The powdered Pulp exhibits abundant débris of large, thin-walled parenchymatous cells but no starch, and not more than an occasional sclerenchymatous cell or group of such cells. No odor; taste intensely bitter. Yields not more than 2 per cent. of fixed oil to *petroleum spirit.* Ash not less than 9 per cent." *Br.*

Barclay considers the estimation of ash in powdered colocynth useful in proving its freedom from seeds. The pulp yields from 8.6 to 14 per cent. of ash, the seeds from 2 to 4 per cent., the whole apple 4.6 per cent. (*Am. Drug.*, 1896, 152.) Water and alcohol extract the virtues of colocynth. It is a matter of importance to be able to determine whether the drug miller who usually powders colocynth is careful to reject the seeds. If the seeds have been ground with the dried pulp, the microscope will show the presence of numerous albuminous granules derived from the cotyledons. (W. T. Clark, *P. J.*, vii, 509.) These are best found by putting a small amount of the powder on the glass slide, adding a drop of water, and gently rubbing the cover glass over it; fragments of the double-walled embryo sac show on the outer side elongated, more or less hexagonal, thin-walled cells, and on the inner side irregular, tabular, thick-walled cells. If powdered colocynth contains a large number of starch granules it has probably been adulterated. Power and Moore (*Tr. Chem. Soc.*, xcvii, p. 99) have separated from colocynth an alkaloidal principle which has a violent purgative effect, but this is not the only active principle of the crude drug, because both ether and chloroform extracts of the resin, when free from the alkaloidal principle, were still purgative. They find also alpha-elaterin, but none of the active beta-elaterin. (See *Elaterinum.*) Vauquelin obtained the bitter principle of colocynth in a separate state, and called it *colocynthin.* According to Meissner, 100 parts of the dry pulp of colocynth contain 14.4 parts of colocynthin, 10.0 of extractive, 4.2 of fixed oil, 13.2 of a resinous substance insoluble in ether, 9.5 of gum, 3.0 of pectic acid (pectin), 17.6 of gummy extract derived from the lignin by means of potassium hydroxide, 2.7 of calcium phosphate, 3.0 of magnesium phosphate, and 19.0 of lignin, besides water. Walz supposed that he had found another peculiar principle, *colocynthitin.* It was obtained by treating with ether the alcoholic extract previously exhausted by water, decolorizing the ethereal solution with animal charcoal, evaporating to dryness, and dissolving the residue in anhydrous alcohol, which deposited it in crystals on spontaneous evaporation. It is white and tasteless, and is probably a resin. (*N. Jahrbuch der Pharm.*, xvi, 10.) Colocynthin is obtained by boiling the pulp in water, evaporating the decoction, treating the extract thus procured with alcohol, evaporating the alcoholic solution, and

submitting the residue, which consists of the bitter principle and potassium acetate, to the action of a little cold water, which dissolves the latter and leaves the greater part of the former untouched. Bastick obtained it by exhausting the pulp with cold water, heating the solution to ebullition, adding lead subacetate so long as a precipitate was produced, filtering the liquor when cold, adding diluted sulphuric acid gradually until it no longer occasioned a precipitate, boiling to expel free acetic acid, filtering to separate lead sulphate, evaporating cautiously nearly to dryness, extracting the colocynthin from the residue by strong alcohol, which left the salts, and finally evaporating the alcoholic solution.

The following process, employed by Walz, yields it in a purer state. Colocynth is exhausted by alcohol of sp. gr. 0.84, the tincture evaporated to dryness, the residue treated with water, and the solution precipitated first with lead acetate and afterwards with lead subacetate. The yellow filtered liquor is then treated with hydrogen sulphide to separate the lead, and, after filtration, with solution of tannic acid, which throws down a compound of tannic acid and colocynthin. This is dissolved in alcohol, the tannin thrown down by lead subacetate, the excess of lead separated, and the liquid digested with animal charcoal, filtered, and evaporated. The residue, washed with anhydrous ether, is pure colocynthin. This is yellowish, somewhat translucent, brittle and friable, fusible by a heat below 100° C. (212° F.), inflammable, more soluble in alcohol than in water, but capable of rendering the latter intensely bitter. Mouchon states that it is insoluble in ether. It is neither acid nor alkaline; but its aqueous solution gives with infusion of galls a copious white precipitate. Ahrends (*Neue Arzneimittel*, 1909) gives the synonym of this principle as *citrullin* and gives the formula as $C_{56}H_{84}O_{23}$. Its formula, according to Walz, is $C_{56}H_{42}O_{23}$. Upon the same authority it is a glucoside, being resolved by the action of sulphuric acid into sugar and a peculiar resinous substance termed *colocyntheïn*, to which he gives the formula $C_{44}H_{32}O_{13}$. Henke doubts the probability of colocynthin being a glucoside, and states that it is uncrystallizable; he reviews the methods of previous investigators, and obtained by his own process but 0.66 per cent. of colocynthin. (*A. Pharm.*, 1883, p. 200; *A. J. P.*, 1883, p. 301.) According to Johannson, colocynthin, when heated with diluted sulphuric acid, yields colocyntheïn, elaterin, and bryonin. (*A. J. P.*, 1885, p. 451.) An infusion of colocynth, made with boiling water, gelatinizes upon cooling. Neumann obtained from 768 parts of the pulp, treated first with alcohol and then with water, 168 parts of alcoholic and 216 of aqueous extract. (See also paper by George Wagner, *Proc. A. Ph. A.*, 1893, 179.)

Uses.—The pulp of colocynth is a powerful drastic, hydragogue cathartic, producing, when given in large doses, violent griping, and sometimes bloody discharges, with dangerous inflammation of the bowels. Death has resulted from a teaspoonful and a half of the powder. (Christison.) Even in moderate doses it sometimes acts with much harshness, and it is therefore seldom prescribed alone. By some writers it is said to be diuretic. It was frequently employed by the ancient Greeks and the Arabians, though its drastic nature was not unknown to them. Among the moderns it is occasionally used in obstinate dropsy, and in various affections depending on disordered action of the brain. In combination with other cathartics it loses much of its violence, but retains its purgative energy, and in this form is extensively employed. The compound extract of colocynth is a favorite preparation with many practitioners, and, combined with calomel, extract of jalap, and gamboge, it forms a highly efficient and safe cathartic, especially useful in congestion of the portal circle and torpidity of the liver. (See *Pilulæ Catharticæ Compositæ.*) It is best administered in minute division, effected by trituration with gum or farinaceous matter. The active principle has sometimes been employed, and, in the impure state in which it is prepared by the process of Emile Mouchon, may be given in the dose of a grain (0.065 Gm.).

Thunberg states that the fruit of *C. Colocynthis*, at the Cape of Good Hope, is rendered so mild by being properly pickled that it is eaten both by the natives and by the colonists; but, as it is thus employed before attaining perfect maturity, it is possible that the drastic principle may not have been developed.

Dose, one to five grains (0.065–0.32 Gm.).

CONFECTIO PIPERIS. Br.

(cŏn-fĕc'tĭ-ō pĭp'ĕ-rĭs)

Electuarium Piperis; Electuaire de Poivre, *Fr.*; Pfefferlatwerge, *G.*

"Black pepper of commerce, in powder, 100 *grammes;* Caraway Fruit, in powder, 150 *grammes;* Purified Honey, 750 *grammes.* Mix." *Br.*

This preparation was intended as a substitute for *Ward's Paste*, which acquired some reputation in Great Britain as a remedy in *piles* and ulcers of the rectum. To be of service, it must be continued, according to Brodie, for two, three, or four months. Its stimulating properties render it inapplicable to cases attended with much inflammation.

Dose, from one to two drachms (3.9–7.7 Gm.), repeated two or three times a day.

CONFECTIO ROSÆ GALLICÆ. Br.

CONFECTION OF ROSES

(cŏn-fĕc'tĭ-ō rō'şæ găl'lĭ-cæ)

Conserva Rosarum; Conserve de Rose, *Fr. Cod.*; Conserve de Rose rouge, *Fr.*; Rosen-Conserve, *G.*

Confection of Rose was unfortunately dropped from the U. S. P. IX, but was introduced into the National Formulary IV. (See Part III.)

"Fresh Red-Rose Petals, 250 *grammes;* Refined Sugar, 750 *grammes.* Beat together in a stone mortar," *Br.*

* "Red Rose, in No. 60 powder, *eighty grammes* [or 2 ounces av., 360 grains]; Sugar, in fine powder, *six hundred and forty grammes* [or 22 ounces av., 252 grains]; Clarified Honey, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Stronger Rose Water, *one hundred and sixty cubic centimeters* [or 5 fluidounces, 197 minims], to make about *one thousand grammes* [or 35 ounces av., 120 grains]. Rub the Red Rose with the Stronger Rose Water previously heated to 65° C. (149° F.), then gradually add the Sugar and Clarified Honey, and beat the whole together until a uniform mass results." *U. S. VIII.*

In the British process the unblown petals only are used, and these should be deprived of their claws; in other words, the rose-buds should be cut off a short distance above their base, and the lower portion rejected. In the last four editions of the U. S. Pharmacopœia, dried roses have been substituted for the fresh, as the latter are not brought to our market. The process is very similar to that of the French Codex. We have been informed, however, that confection of rose is still made in Philadelphia on a large scale from the fresh petals of the *R. centifolia* and others, by beating them into a pulp with sugar, as in the British process. An excuse for this deviation from the official formula is, that the confection thus made has greater adhesiveness than the official, and is therefore better fitted for the formation of pills. Confection of Rose is slightly astringent; it is used almost exclusively as a vehicle, and is admirably adapted as an excipient and to impart consistence to the pilular mass.

Off. Prep.—Pilula Hydrargyri, *Br*

CONFECTIO SENNÆ. Br.

CONFECTION OF SENNA

(cŏn-fĕc'tĭ-ō sĕn'næ)

Electuarium Sennæ Compositum, Electuarium Lenitivum; Electuaire de Séné composé, *Fr. Cod.*; Electuaire lenitif, *Fr.*; Electuarium e Senna, *P. G.*; Sennalatwerge, *G.*; Elettuario lenitivo, *It.*

Confection of Senna was improperly dropped from the U. S. P. IX, but the National Formulary IV introduced the U. S. P. VIII preparation. (See Part III.)

"Senna Leaves, in powder, 100 *grammes;* Coriander Fruit, in powder, 40 *grammes;* Figs of commerce, 160 *grammes;* Tamarinds, 120 *grammes;* Cassia Pulp, 120 *grammes;* Prunes of commerce, 80 *grammes;* Extract of Liquorice, 15 *grammes;* Refined Sugar, 400 *grammes;* Distilled Water sufficient to produce 1000 *grammes.* Boil the figs and prunes gently with three hundred and fifty grammes of Distilled Water in a covered vessel for four hours; add more Distilled Water to make up the quantity to its original weight, and then incorporate the Tamarinds and Cassia Pulp; digest for two hours; rub the softened pulp of the fruits through a hair sieve, rejecting the seeds and other hard parts; to the pulp thus obtained add the Refined Sugar and Extract of Liquorice, dissolving them by the aid of gentle heat; while the mixture is still warm, add to it gradually the mixed Senna and Coriander powders; mix the whole thoroughly; make the weight of the resulting Confection one thousand grammes, either by evaporation or by the addition of more Distilled Water." *Br.*

* "Senna, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Cassia Fistula, bruised, *one hundred and sixty grammes* [or 5 ounces av., 282 grains]; Tamarind, *one hundred grammes* [or 3 ounces av., 231 grains]; Prune, sliced, *seventy grammes* [or 2 ounces av., 205 grains]; Fig, bruised, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Sugar, in fine powder, *five hundred and fifty-five grammes* [or 19 ounces av., 252 grains]; Oil of Coriander, *five grammes* [or 77 grains]; Water, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Digest the Cassia Fistula, Tamarind, Prune and Fig with *five hundred cubic centimeters* [or 17 fluidounces] of Water in a covered vessel, by means of a water-bath, for three hours. Separate the coarser portions and rub the pulpy mass, first through a coarse hair sieve, and then through a muslin cloth. Mix the residue with *one hundred and fifty cubic centimeters* [or 5 fluidounces] of Water, and, having digested the mixture for a short time, treat it as before, and add the product to the pulpy mass first obtained. Then, by means of a water-bath, dissolve the Sugar in the pulpy liquid, and evaporate the whole in a tared vessel, until it weighs *eight hundred and ninety-five grammes* [or 31 ounces av., 250 grains]. Lastly, add the Senna and the Oil of Coriander, and incorporate them thoroughly with the other ingredients while they are yet warm." *U. S. VIII.*

Confection of Senna, when correctly made, is an elegant preparation, and keeps well if properly protected. The U. S. P. VIII process differed from that of 1860 in preparing the pulps, as suggested in former editions of this Dispensatory, instead of taking them already prepared. An improvement was made in the process of the U. S. P. 1890 by replacing the coriander seed of the former Pharmacopœias with oil of coriander; it is almost impossible to powder coriander fine enough to avoid hard particles except by drying it to such an extent as to deprive it injuriously of its volatile oil, and the plan of using the oil directly has therefore been adopted. The oil of coriander should be dropped upon a

portion of the powdered senna contained in a mortar or suitable vessel and this lightly triturated with the rest of the powdered senna so as to distribute it uniformly; the mixture should then be added to the pulpy mass and the official directions then carried out. It was formerly not uncommon to omit the cassia pulp in this preparation, as the pods were not always to be found in the market; but, as this is next to the senna the most active ingredient, the omission was to be regretted. Cassia fistula is now readily procured in commerce, and there can be no excuse for its omission. It has also been proposed to substitute the fluidextract of senna for the crude drug (*A. J. P.*, xliii, 123); but, as the fluidextract is of such uncertain quality, the leaves themselves are preferable.

A very good, pleasant laxative, admirably adapted to cases of habitual costiveness, especially in pregnant women, and in persons affected with *piles*.

Dose, one to two drachms (3.9–7.7 Gm.), at bedtime.

CONFECTIO SULPHURIS. Br.

CONFECTION OF SULPHUR

(cŏn-fĕc'tĭ-ō sŭl'phŭ-rĭs)

Electuarium Sulphuris; Electuaire de Soufre, *Fr.*; Schwefellatwerge, *G.*

"Precipitated Sulphur, 450 *grammes;* Acid Potassium Tartrate, in powder, 110 *grammes;* Tragacanth, in powder, 5 *grammes;* Syrup, 210 *millilitres;* Tincture of Orange, 55 *millilitres;* Glycerin, 170 *millilitres.* Mix." *Br.*

This is merely a mode of administering the two laxatives, sulphur and potassium bitartrate, and the relative proportion of the latter is so small that it can have little effect. The addition of tragacanth is due to a suggestion of Peter Boa, who found that without it a syrupy layer of liquid formed on top of the confection. (*P. J.*, 1882, 682.) The syrup of orange peel, formerly directed, has been replaced in the last two Editions by syrup and tincture of orange, evidently because the syrup of orange peel did not keep well, while the glycerin serves to retain the proper consistence of the confection.

Dose, one to two drachms (3.9–7.7 Gm.) or more.

CONFECTIONES

CONFECTIONS

(cŏn-fĕc-tĭ-ō'nēs)

Electuaries; Conserves, Électuaires, Saccharolés mous, *Fr.*; Conserven, Latwergen, *G.*; Elettuario, *It.*; Electuario, *Sp.*

Under the general title of Confections, the Pharmacopœias include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. But two confections, Rose and Senna, were retained in the Eighth Revision of the U. S. Pharmacopœia and in the Ninth Revision both were dropped and relegated to the National Formulary IV. The old division into Conserves and Electuaries has been abandoned; but, as there is some ground for the distinction, we shall make a few general remarks upon each division before proceeding to the consideration of the individual preparations.

Conserves consist of undried vegetable substances and refined sugar beaten into a uniform mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But, as active medicines even thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now used are intended rather as convenient vehicles of other substances than for separate exhibition. The sugar used in their preparation should be in fine powder.

Electuaries are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for official direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Different substances require different proportions of syrup. Light vegetable powders usually require twice their weight, gum-resins two-thirds of their weight, resins somewhat less, mineral substances about half their weight, and deliquescent salts not more than one-tenth. Should the electuary become dry and hard, more syrup should be added, so as to give it the requisite consistence. If the dryness result from the mere evaporation of the aqueous part, water should be added instead of syrup, and the same remark is applicable to the conserves. To prevent the hardening of electuaries, the French writers recommend the use of syrup prepared from brown sugar, which is less apt to crystallize than that made from the refined. Molasses would answer the same purpose, but its taste might be objectionable. Some employ honey, but this is not always acceptable to the stomach. Glycerin and syrupy glucose might sometimes be used with advantage.

Confectio Aromatica, Aromatic Confection, Electuarium Aromaticum; Electuaire (Confection) aromatique, *Fr.;* Aromatische Latwerge, Getwürzlatwerge, *G.*—"Take of Aromatic Powder *four troyounces;* Clarified Honey, *four troyounces,* or *a sufficient quantity.* Rub the Aromatic Powder with Clarified Honey until a uniform mass of the proper consistence is obtained." *U. S.*, 1870.

This confection affords a convenient means of administering the spices contained in it, and an agreeable vehicle for other medicines. The confection is given in debilitated states of the stomach. The *dose* is from ten to sixty grains (0.65–3.9 Gm.).

Confectio Aurantii Corticis, Confection of Orange Peel, Conserva Aurantii; Conserve d'Ecorce d'Orange, *Fr.;* Apfelsinenschalen-Conserve, *G.*—"Take of Sweet Orange Peel, recently separated from the fruit by grating, *twelve troyounces;* Sugar [refined], *thirty-six troyounces.* Beat the Orange Peel with the Sugar, gradually added, until they are thoroughly mixed." *U. S.,* 1870.

This confection is not used as frequently as it deserves to be. It is, when well made, a grateful aromatic vehicle or adjuvant for tonic and purgative powders.

Confectio Opii, Confection of Opium, which was the modern substitute for the mediæval preparations known as *theriaca* and *mithridate,* has been finally dropped from both Pharmacopœias. One grain of opium was contained in about thirty-six grains of the former United States confection, and in about forty grains of the British. The following is the U. S. Pharmacopœia (1870) formula: "Take of Opium, in fine powder, *two hundred and seventy grains;* Aromatic Powder, *six troyounces;* Clarified Honey, *fourteen troyounces.* Rub the Opium with the Aromatic Powder, then add the Honey, and beat the whole together until thoroughly mixed." *U. S.,* 1870.

COPAIBA. U. S., Br.

COPAIBA Copaib. [Balsam of Copaiba, Copaiva]

(cō-pā'ĭ-bą)

"An oleoresin derived from South American species of *Copaiba* (Fam. *Leguminosæ*)." *U. S.* "Copaiba is the oleo-resin obtained by incision from the trunk of various species of Copaifera, *Linn.*" *Br.*

Balsamum Copaiferarum; Balsam Copaiba, Balsam Capivi; Copahu, *Fr. Cod.;* Oléo-résine (Baume) de Copahu, *Fr.;* Balsamum Copaivæ, *P. G.;* Copaiva; Copaivabalsam, *G.;* Balsamo di Copaive, *It.;* Copaiba, Balsamo de Copaiva, *Sp.*

Copaiba was first noticed in a work published by Purchas, in England, in 1625. The next reference to it was by Cristoval d'Acuña, in 1638. In 1648, Marcgraf and Piso gave a detailed account of the tree which produces it, and the methods of gathering it. Jacquin in 1763 described a species of Copaifera, growing in Martinique, which he named *C. officinalis.* As this was believed to be the same plant with the one observed by Marcgraf in Brazil, it was adopted in the Pharmacopœias, but their identity was denied; and Desfontaines proposed for Jacquin's species the title of *C. Jacquini,* in honor of that botanist. It is now known that many species of *Copaiba* (*Copaifera*) exist in South America, and all of them, according to Martius, yield copaiba. Besides *C. officinalis* (L.) Jacquin, the following yield Copaiba: *C. guianensis* (Desf.) O. Kuntze, *C. Langsdorffii* (Desf.) O. Kuntze, and *C. coriacea* (Mart.) O. Kuntze.

The juice is obtained by making a square chamber in the stems of the trees, reaching to the very center; and the operation is said to be repeated several times during the same season. It is asserted that a single tree will yield about forty liters. As it flows from the wound, it is clear, colorless, and very thin, but it soon acquires a thicker consistence, and a yellowish tinge. It is most largely collected in the provinces of Para and Maranham, in Brazil, and is brought to this country from the port of Para, in small casks or barrels. Large quantities of it come from Maracaibo, in Venezuela, and from other ports on the Caribbean Sea, whence it is brought in casks, demijohns, cans, jugs, etc. The drug is also exported from Angostura, Cayenne, Rio Janeiro, and some of the West India islands.

C. officinalis is a native of Venezuela, and grows in the province of Carthagena, mingled with the trees which afford the balsam of Tolu. It grows also in some of the West India islands, particularly Trinidad and Martinique. This is the source of the Maracaibo or Venezuela Copaiba, which is also obtained in part from *C. guianensis.* This variety of Copaiba is distinguished by being dextrogyrate, more viscid and darker in color.

Numerous varieties of true South American copaiba exist in commerce, known under the name of the various ports of shipment. The most important of these varieties besides Maracaibo is the Para or Maranham Copaibo, which is derived from *C. Langsdorffii* and *C. coriacea,* which is characterized by being optically lævogyrate. The other varieties are Bahia, Carthagena, Maranham, and Cayenne. Each one of these varieties has been referred (see *P. J.,* 1901, lxvi, 325) to a special species of the genus Copaiba, but there is little reason for supposing that this reference is accurate, and there is much reason for believing that various trees contribute to a single variety of copaiba. The following table, according to the researches of Umney and Bennett, shows the specific gravities and percentage of oil of the five most important of these copaibas:

Name.	Sp. gr.	Per cent. of oil.	Resin.
Bahia	0.938	49.7	Soft.
Carthagena	0.970	41.3	Brittle.
Maracaibo	0.969	42.5	Firm, but not easily pulverized.
Maranham	0.990	41.8	Brittle.
Para	0.920	62.4	Very soft.

All of the above varieties answered to the solubility and Gurjun balsam tests.

It will be noticed that the Para and Bahia specimens examined by Umney failed to comply with the tests of the U. S. Pharmacopœia (1890), and yet, supposing that the oil represents the chief therapeutic principle of copaiba, these varieties lead all the others. The German

Pharmacopœia requires that the specific gravity shall be 0.98 to 0.99, and that the acid number shall fall between 75.6 and 84, and the ester number be not more than 8.4. Dieterich. (*P. J.*, April, 1899, and March, 1900.) *Surinam copaiba* is a yellowish or brownish-yellow liquid, of varying consistence; it may be distinguished from Maracaibo copaiba by the fact that one drop of it dissolved in 1 mil of acetic anhydride gives a fine blue color on the addition of a drop of sulphuric acid. (*P. J.*, Nov., 1904.)

According to E. Keto, copaiba of Maracaibo has a density of 0.999; a coefficient of acidity of 85.4; of etherification of 6.7; while that of Para has a density of 0.92; a coefficient of acidity of 19.4; of etherification of 7.4.

Properties.—Copaiba is a clear, transparent liquid, usually of the consistence of olive oil, of a pale yellow color, a peculiar not unpleasant odor, and a bitterish, hot, nauseous taste. Its sp. gr. varies ordinarily from 0.950 to 1.000, but has been known to be as low as 0.916. (Procter, *A. J. P.*, xxii, 292.) It is insoluble in water, but entirely soluble in absolute alcohol, ether, and the fixed and volatile oils. Strong alkaline solutions dissolve it perfectly; but the resulting solution becomes turbid when largely diluted with water. With the alkalies and alkaline earths it forms compounds, in which the resin of the copaiba acts the part of an acid. It dissolves magnesia, especially with the aid of heat, and even disengages carbon dioxide from the magnesium carbonate. If triturated with a sixteenth of its weight of magnesium oxide and a little water and set aside, it gradually assumes a solid consistence, and a similar change is produced with calcium hydroxide. *Solid Copaiba* or *Mass of Copaiba* was official in the U. S. P., 1890, and is now official in the National Formulary IV, Part III. See also U. S. Dispensatory, 19th edition, p. 398. The essential consituents of copaiba are volatile oil and resin, with at times small quantities of acids. As it contains no benzoic acid, it cannot properly be called *balsam of copaiba.* The substances which it most closely resembles, both in composition and in properties, are the turpentines. (See *Oleum Copaibæ.*) For a description of an apparatus for distilling the volatile oil, see a paper by R. A. Cripps in *C. D.*, 1892, 282. Cripps found commercial copaiba to contain the following percentages of volatile oil: 40.95, 45, 45.3, 46.4, 47.8, 48.2, 49.6, 50.4, 50.8, 53.3, 59.6. J. C. Umney (*A. J. P.*, 1893, 544) found in African copaiba 39 per cent. of an oil of 0.918 specific gravity and with a rotation of + 20° 42′, the last character distinguishing it from the other varieties which yield lævorotatory oils.

The official description of Copaiba is as follows: "A pale yellow to brownish-yellow, more or less viscid liquid, either without fluorescence or with only a slightly greenish fluorescence; having a peculiar, aromatic odor, and a persistent, bitter, and acrid taste. It is insoluble in water and partly soluble in alcohol. Soluble, showing not more than a slight opalescence, in dehydrated alcohol, carbon disulphide, or in fixed or volatile oils; completely soluble in chloroform or ether and also soluble in an equal volume of petroleum benzin, a further addition of the solvent producing a flocculent precipitate. Specific gravity: 0.940 to 0.995 at 25° C. (77° F.). When heated on a water bath, no odor of oil of turpentine is evolved; and when all of the volatile oil has been driven off, a hard and brittle resin remains, weighing not less than 36 per cent. of the original weight of the Copaiba taken (*paraffin or fatty oils*). To about 1 Gm. of Copaiba, accurately weighed, add 50 mils of alcohol and 1 mil of phenolphthalein T.S., then titrate the solution with half-normal potassium hydroxide V.S. It shows an acid value of not less than 28 nor more than 95. Dissolve 3 or 4 drops of the volatile oil separated from Copaiba by distillation with steam, in 3 mils of glacial acetic acid, mix the solution with 1 drop of a freshly prepared aqueous solution of sodium nitrite (1 in 10), and carefully underlay this with 2 mils of sulphuric acid. The acetic layer is not colored pink (*gurjun balsam*). Shake 5 mils of Copaiba with 15 mils of alcohol and then heat the mixture to boiling for one minute; no oil separates after cooling and allowing it to stand for one hour (*paraffin oils*). The volatile oil separated from Copaiba by distillation with steam does not boil below 250° C. (482° F.), and shows an angle of rotation in a 100 mm. tube of not less than –7° at 25° C. (77° F.). (*African Copaiba*)." *U. S.*

"A more or less viscous liquid, generally transparent and occasionally fluorescent, yellow to golden brown. Specific gravity 0.975 to 0.995. Entirely soluble in *absolute alcohol*; soluble in four times its volume of *petroleum spirit*, the solution yielding only a slight filmy deposit on standing. Aromatic, characteristic odor; taste acrid, somewhat bitter, persistent. Loses about 45 per cent. of its weight when heated for forty-eight hours to 100° C. (212° F.). Forms a transparent solution with one-third of its volume of *solution of ammonia.* Four drops carefully added to a mixture of 5 millilitres of *glacial acetic acid* with four drops of *nitric acid* do not yield a purplish or violet color (absence of gurjun balsam). 1 gramme dissolved in 25 millilitres of *absolute alcohol* requires for neutralisation not less than 2.7 millilitres of *N/2 alcoholic solution of potassium hydroxide, solution of phenolphthalein* being used as indicator (presence of a due proportion of acid resins). The volatile oil distilled from it responds to the tests described under 'Oleum Copaibæ.'" *Br.*

The *resinous* mass which remains after the distillation of the oil is hard, brittle, translucent, greenish-brown, and nearly destitute of odor and taste. By mixing it with the oil in proper proportion, we may obtain a liquid identical or nearly so with the original juice. This resinous mass is of an acid character, and yields a series of amorphous salts; it may be obtained pure by exposing a mixture of 9 parts of copaiba and 2 parts of aqueous ammonia (sp.

gr. 0.95) to a temperature of 10° C. (50° F.). In this way crystals of *copaivic acid,* $C_{20}H_{30}O_2$, are obtained. This acid agrees with the *abietic acid* of rosin in composition, but not in properties. Copaivic acid is readily soluble in alcohol, and especially in warmed copaiba itself; much less soluble in ether. When recrystallized from alcohol, copaivic acid fuses at 116° to 117° C. (241°–242.6° F.). (*A. J. P.,* 1879, p. 305.)

An analogous substance, *oxycopaivic acid,* $C_{20}H_{28}O_3$, was found in 1841 by H. von Fehling in Para copaiba, and Strauss, in 1865, extracted *meta-copaivic acid,* $C_{20}H_{34}O_4$, from Maracaibo copaiba. Copaivic acid forms crystallizable salts with alkalies, and *sodium copaivate,* $NaC_{20}H_{29}O_2$, made by combining molecular quantities of the acid and soda, is asserted by Zlamál and Roquette to be more efficient than any other preparation of copaiba. Tschirch (*Harze und Harzbehälter,* 1900, p. 297) obtained from Maracaibo balsam a crystalline resin acid corresponding in many respects with Strauss's metacopaivic acid, to which, however, he gave the formula $C_{11}H_{16}O_2$, finding a melting point 89° to 90° C. (192.2°–194° F.) as against 205° to 206° C. (401°–402.8° F.) for Strauss's acid. Para balsam was found by Tschirch to contain two crystallizable resin acids together with several uncrystallizable ones. African copaiba balsam he found to contain a characteristic acid to which he gave the name *illurinic acid* and the formula $C_{14}H_{20}O_2$ or possibly $C_{21}H_{30}O_3$. Keto, who worked out the preceding results jointly with Tschirch, has since published some additional results. (*J. P. C.,* 1902, p. 381.) He finds in Para balsam the two crystallizable acids referred to above, one of which he names *paracopaibic acid* with the formula $C_{20}H_{32}O_3$ and fusing point 142° to 145° C. (287.6°–293° F.), and the other *homoparacopaibic acid,* $C_{18}H_{28}O_3$, fusing at 111° to 112° C. (231.8°–233.6° F.). To *illurinic acid* mentioned by Tschirch he gives the formula $C_{20}H_{28}O_3$ and the melting point 128° C. (262.4° F.).

Copaiba, upon exposure to the air, acquires a deep color, a thicker consistence, and greater density, and, if spread out upon an extended surface, ultimately becomes dry and brittle. This change is owing partly to the volatilization and partly to the oxidation of the essential oil. As it is the soft resin that results from the oxidation of the oil, it follows that the proportion of this resin increases with age. Considerable diversity must, therefore, exist in the drug, and in its physical properties and in the proportions of its ingredients, according to its age and degree of exposure. Similar differences also exist in the copaiba procured from different sources. Thus, that of the *West Indies,* when compared with the *Brazilian,* which is the variety above described, and in common use, is of a thicker consistence, of a deeper or darker yellow color, less transparent, and of a less agreeable, more terebinthinate odor. They differ also, as observed by Buignet, in their action on polarized light, in which they differ not only in degree, but sometimes also even in direction. (*J. P. C.,* Oct., 1861, pp. 266–7.) It is not impossible that differences may exist in the drug according to the circumstances of its collection. The species of Copaifera from which the oleoresin is collected, as well as the age of the tree, its position, and the season of collection, must also have influence over the product. It is highly probable that the resinous matter results from the oxidation of the oil in the cells of the plant, and that the less elaborated the oleoresin may be, the larger proportion it will contain of the oil. It is said that a volatile oil flows abundantly from a tree near Bogota, which is employed to adulterate the copaiba collected in that vicinity and shipped from Maracaibo and other neighboring ports. *African Copaiba,* or *Balsam of Illurine,* which reached the London market first in 1891, from West Africa, is a brownish substance, having a consistency similar to the Maracaibo copaiba, and a greenish fluorescence. Its aromatic odor is entirely different from that of copaiba; its taste is biting, with an after-taste of bitterness. According to Keto (*J. P. C.,* 1902, 381), its density is 0.9905; its coefficient of acidity 55.5; of etherification 8.3. It is soluble in chloroform and petroleum benzin, also in ether, with which it makes an opalescent liquid. Its solution in absolute alcohol, or alcohol of 95 per cent. is not limpid. From it Keto separated *illurinic acid.* Its volatile oil is of a pale yellow color, with a strong odor entirely different from that of copaiba. The residue which remains after the distillation consists of two resins, one soluble, the other insoluble, in alcohol. This oleoresin probably shares the medicinal properties of true copaiba, and is the product of *Hardwickia Mannii* Oliver, a tree closely allied to the true copaibas. (See *Apoth. Zeit.,* 1894, p. 9.)

Adulterations.—Copaiba is often adulterated with a fixed oil, especially castor oil, which, in consequence of its solubility, cannot, like the others, be detected by alcohol. Various plans have been proposed for recognizing the castor oil. The simplest is to boil a drachm of the copaiba in a pint of water until the liquid is wholly evaporated. If the copaiba contains a fixed oil, the residue will be more or less soft, according to the quantity present; otherwise it will be hard. Magnesium carbonate, potassium hydroxide, and sulphuric acid have also been proposed as tests. In the old Edinburgh Pharmacopœia it was stated that copaiba "dissolves a fourth part of its weight of magnesium carbonate, with the aid of a gentle heat, and continues translucent." The presence of a small proportion of any fixed oil renders the mixture opaque. One part of potassium hydroxide dissolved in two of water forms a clear solution with nine parts of pure copaiba, and the liquid continues clear when moderately diluted with water or alcohol; but the presence of one-sixth of fixed oil in the copaiba occasions more or less opacity in the liquid, and half the quantity causes the precipitation of white flakes in

a few hours. (Stolze.) Turpentine, which is said to be sometimes added to copaiba, may be detected by its odor, especially if the copaiba be heated. According to Redwood, most of the proposed tests of the purity of copaiba are liable to fallacy, and the best measure of its activity is the quantity of volatile oil it affords by distillation. Castor oil, Venice turpentine, linseed oil, or gurjun balsam may be detected by means of petroleum benzin, which makes a clear solution with pure copaiba, but if either of the substances mentioned be present a milky mixture, which soon settles into two layers, is formed, the copaiba solution being on top. (*A. J. P.*, July, 1873; *Proc. A. Ph. A.*, xxiv, 191, xxvi, 286.) Maisch has found that *ten* volumes of petroleum benzin, instead of *three* as proposed by Wayne, must be added to one of copaiba to get the best results from this test. Indeed, it has been shown that pure copaiba will sometimes show turbidity when mixed with petroleum benzin. (*A. J. P.*, 1877, p. 131.) Some years since, a substance was imported into New York, under the name of *red copaiba,* which did not possess a single characteristic of the genuine drug. It was of a thick, semi-fluid consistence, not unlike that of balsam of Tolu, as it often reaches us, of a brown color similar to that of the same balsam, though darker, and of an unpleasant yet somewhat aromatic odor, recalling that of liquidambar, but less agreeable. Its origin is unknown. Hager recommends the use of absolute alcohol, which he says completely dissolves, without turbidity, all the varieties of copaiba except the Para, whose solution on standing clears itself by the deposition of a few white flakes. J. M. Fulton asserts that some pure copaibas are not entirely dissolved by absolute alcohol. (*A. J. P.*, 1877.) For additional tests and criticisms by Beckurts and Brueche, see *A. Pharm.*, 1891, p. 90; also *Proc. A. Ph. A.*, 1892, 635. For Hager's test, see *C. D.*, 1894, 740. Dodge and Olcott (*Am. Drug.*, 1895, 5) describe a test to detect gurjun balsam in copaiba, which Kebler regards as the most reliable yet proposed; it is as follows. Four drops of the suspected sample, dissolved in half a fluidounce of glacial acetic acid, will, if pure, remain colorless and clear, or but slightly cloudy, if from four to six drops of pure nitric acid be dropped into the solution. If the sample be pure gurjun balsam, the mixture will have a deep purple color; if a mixture of the two balsams, the depth of color will vary according to the amount of the adulterant, as small a proportion as 2 per cent. being discoverable; a modification of this test is now official. (See also *A. J. P.*, 1896, 143, and 1897, 394.) For a valuable paper on Copaiba by A. R. L. Dohme, see *Proc. A. Ph. A.*, 1904, 322.

Uses.—Copaiba is gently stimulant, diuretic, laxative, and in very large doses often actively purgative. It produces, when swallowed, a sense of heat in the throat and stomach, and extends an irritant action not only throughout the alimentary canal, but also to the urinary passages, and in fact, in a greater or less degree, to the whole mucous membrane, for which it appears to have a strong affinity. The urine acquires a peculiar odor during its use, and its odor may be detected in the breath. It sometimes occasions an eruption upon the skin resembling that of measles, and attended with disagreeable itching and tingling, or even violent pemphigus. (*N. Y. M. J.*, Jan., 1873, p. 416.) Nausea and vomiting, painful purgation, strangury and bloody urine, and a general state of fever are caused by excessive doses. As a remedy it has been found useful in *catarrhs,* particularly those of a chronic character. Thus, it is given with occasional advantage in *leucorrhea, chronic cystitis, chronic diarrhea, hemorrhoids,* and *chronic bronchitis.* The complaint, however, in which it is most employed is *gonorrhea.* It should not be administered in the first stages, when the inflammation is severe and acute, nor is it applicable to very chronic forms of the disorder, such as gleet. It was formerly much esteemed as a vulnerary and as an application to *ulcers,* but it is now seldom used externally. Ruschenberger recommends it locally in *chilblains.* (*Med. Examiner,* i, 77.)

Both the volatile oil and the resin are eliminated by the kidneys in an altered condition; if to the urine of a person taking the drug, nitric acid be added, a precipitate is thrown down, which may be mistaken for albumin. The volatile oil is more active than is the resin, which is not, however, inert. Wilks, of Guy's Hospital, London, speaks of the resin with great confidence as a hydragogue diuretic in obstinate *dropsy,* given in the dose of fifteen or twenty grains three times a day.

It may be given dropped on sugar, but in this form is often so exceedingly offensive as to render some concealment of its nauseous qualities necessary. A less disagreeable form is that of emulsion, prepared by rubbing the copaiba first with mucilage, or the yolk of an egg, and sugar, and afterwards with some aromatic water, as that of mint or cinnamon. The *volatile oil,* which is official in the British Pharmacopœia, may be given in the dose of ten or fifteen minims (0.6–0.9 mil) in emulsion, or, as is almost universally preferred, in capsules.

Dose, of copaiba, from fifteen minims to a fluidrachm (1.0–3.75 mils) three times a day, or a smaller quantity repeated more frequently.

CORIANDRUM. U. S. (Br.)

CORIANDER Coriand. [Coriander Seed]

(cō-rĭ-ăn'drum)

"The dried ripe fruit of *Coriandrum sativum* Linné (Fam. *Umbelliferæ*), without the presence or admixture of more than 5 per cent. of other fruits, seeds, or foreign matter." *U. S.* "Coriander Fruit is the dried ripe fruit of Coriandrum sativum, *Linn.*" *Br.*

Coriandri Fructus, *Br.;* Coriander Fruit; Coriandre, *Fr. Cod.;* Koriander, *G.;* Coriandro, *It.;* Cilantro, *Sp.*

Coriandrum sativum is an annual plant, with an erect branching stem rising about two feet, and furnished with compound leaves, of which the upper are thrice ternate, with linear pointed leaflets, the lower pinnate, with the pinnæ cut into irregular serrated lobes like those of parsley. The flowers are white or rose-colored, and in compound terminal umbels; the fruit globular, and composed of two concavo-convex mericarps. *C. sativum* is a native of Italy, but at present grows wild in most parts of Europe, having become naturalized in consequence of its extended cultivation. The flowers appear in June, and the fruit ripens in August. It is a singular fact that all parts of the fresh plant are extremely fetid when bruised, while the fruit becomes fragrant by drying. This is the official portion. The chief supplies come from Russia, Morocco, Holland, and Hungary. Attempts have been made to cultivate the plant in Vermont. The amount annually imported into the United States is over 1,000,000 pounds. The drug not infrequently contains a large admixture of earthy and stony substances as well as stems and similar inert matter. Blome reports finding a sample of Coriander that contained 20 per cent. of flaxseed. LaWall has found leguminous starch in a specimen of powdered Coriander, probably from vetch seed which is sometimes accidentally present.

The fruit is officially described as follows: "Mericarps usually coherent; cremocarp nearly globular, from 3 to 5 mm. in diameter; externally light brown or rose colored; summit with 5 calyx teeth and a short stylopodium, each mericarp with 5 prominent, straight, longitudinal, primary ribs and 4 indistinct, undulate secondary ribs; mericarps easily separated, deeply concave on the inner or commissural surface and showing in transverse section 2 vittæ (oil tubes) on the inner surface of each. Under the microscope, sections of Coriander show an epidermis of small cells with thick walls; a layer of several rows of thin-walled more or less collapsed parenchyma separated from a broad zone of strongly lignified, sclerenchymatous fibers which extend as a continuous ring in the mesocarp of each of the mericarps; 2 or 3 layers of large, tangentially elongated, thin-walled parenchyma cells, frequently with numerous large lysigenous intercellular spaces; inner epidermis of large tabular cells, the inner yellowish walls being considerably thickened and closely coherent to the brownish cells of the seed-coat; commissural surface with 2 large, elliptical vittæ; the cells of the pericarp separated from the seed-coat and forming a large elliptical cavity; endosperm distinctly reniform in outline and consisting of tabular or polygonal thick-walled cells containing numerous large aleurone grains each with a rosette aggregate or prism of calcium oxalate. The powder is light brown, consisting chiefly of fragments of endosperm and lignified tissues of the pericarp; calcium oxalate crystals numerous, from 0.003 to 0.01 mm. in diameter, mostly in rosette aggregates, either isolated or in aleurone grains; sclerenchymatous fibers irregularly curved, having thick, yellowish, lignified walls and numerous simple pores; numerous globules of fixed oil; fragments of light yellow vittæ few, associated with elongated polygonal epidermal cells. Coriander yields not less than 0.5 per cent. of volatile extractive, soluble in ether (see Part II, Test No. 12). Coriander yields not more than 7 per cent. of ash." *U. S.*

"Nearly globular, about five millimetres in diameter, uniform brownish-yellow in color, and glabrous. Mericarps usually closely united, and crowned by the calyx teeth and stylopod. Primary ridges wavy and inconspicuous; secondary ridges straight and more prominent. In transverse section, two vittæ on the commissural surface of each mericarp. Aromatic odor, especially when bruised; taste agreeable." *Br.*

The aromatic taste and odor of coriander depend on a *volatile oil,* which may be obtained separate by distillation. One pound of the seeds yields forty-two grains of the oil. (Zeller.) This is colorless or pale yellow, with an agreeable odor of coriander, a mild aromatic taste, and a sp. gr. varying from 0.87 to 0.88. Its main constituent, according to Semmler (*Ber. d. Chem. Ges.,* xxiv, 206), is what was first called *coriandrol,* but is now recognized as right rotatory *linalool,* $C_{10}H_{18}O$, boiling between 194° and 198° C. (381.2°–388.4° F.). Besides this, about 5 per cent. of *dextro-pinene* was isolated, boiling between 156° and 160° C. (312.8°–320° F.). It is one of the most permanent volatile oils, long resisting oxidation. The fruit's virtues are imparted to alcohol by maceration, and less readily to water.

Uses.—Coriander is a rather feeble aromatic. It is almost exclusively employed in combination with other medicines, either to cover their taste, to render them acceptable to the stomach, or to correct their griping qualities. It was well known to the ancients.

Dose, twenty to sixty grains (1.3–3.9 Gm.).

COTARNINÆ HYDROCHLORIDUM. U. S.

COTARNINE HYDROCHLORIDE Cotarn. Hydrochl. [Cotarnine Chloride]

(cō-tär-nī'næ hȳ-drǫ-ȼhlō'rī-dŭm)

"Quarternary oxymethyl-oxymethylene-dihydro-isoquinoline chloride [$C_{12}H_{14}O_3NCl$ or $(CH_3O)(CH_2O_2).C_9H_6N(CH_3)Cl = 255.58$] obtained by hydrolyzing narcotine, and treating the resulting cotarnine [$(CH_3O)(CH_2O_2)C_8H_5(CHO).NH(CH_3)$] with hydrochloric acid." *U. S.*

This compound was introduced into the U. S. P. IX and is officially described as follows: "Cotarnine Hydrochloride occurs as a yellow, crystal-

line powder; odorless and deliquescent in moist air. It is very soluble in water and alcohol, yielding yellow solutions. Its aqueous solution (1 in 20) is neutral to litmus. Silver nitrate T.S. when added to an aqueous solution of Cotarnine Hydrochloride produces a white precipitate insoluble in nitric acid. About 0.2 Gm. of Cotarnine Hydrochloride, dissolved in 10 mils of distilled water, yields a brown precipitate of cotarnine periodide on the addition of 10 mils of tenth-normal iodine V.S. When this precipitate is collected on a filter and dried to constant weight over sulphuric acid, it melts between 142° and 144° C. (287.6° and 291.2° F.). Heat gradually 0.1 Gm. of Cotarnine Hydrochloride over a Bunsen burner; it is decomposed, evolving characteristic, disagreeable vapors and yielding a reddish-brown liquid, which gradually changes to a hard charred mass. No weighable ash remains on the incineration of this mass. Dissolve about 0.5 Gm. of Cotarnine Hydrochloride in 10 mils of distilled water and add 2 mils of an aqueous solution of sodium hydroxide (15 per cent.). A milk-white precipitate is produced which dissolves on agitation, but is reprecipitated from the solution after standing for some time, leaving the supernatant liquid clear and but faintly yellow." *U. S.*

Uses.—The fact that the only chemical difference between hydrastinine and cotarnine is that in the latter OCH_3 is substituted for one atom of hydrogen led Freund to suggest the substitution of cotarnine for hydrastinine. It has been physiologically studied by Falk (*Th. M.*, 1896, x), Kehrer (*Monat. fur Geburts. und Gynakol.*, 1907, xxvi, p. 709), Laidlaw (*Bio-Chem. J.*, 1910, v, p. 243), and others. It differs in its action from hydrastinine, in that it has practically no influence upon the circulation, but resembles it in its depressant action upon the spinal cord, and in its stimulant effect upon the uterine muscle, and according to Laidlaw, also in the fact that it does not increase the coagulability of the blood.

Under the trade names of *stypticin* and *styptol* the hydrochloride and phthalate of cotarnine, respectively, have been extensively used in the treatment of various forms of *hemorrhage*, especially those from the uterus. Of their value in *menorrhagia* and *metrorrhagia* there is hardly any room for doubt, but that they are equally successful in hemorrhages from other parts of the body, may be questioned, although there is some clinical evidence as to their utility. Each of these preparations is marketed in the form of tablets, containing five-sixths of a grain (0.05 Gm.), of which one to two may be given at a dose, and repeated several times daily. Single doses may be given hypodermically in cases of emergency, as high as three or four grains (0.2–0.26 Gm.).

A double salt of cotarnine hydrochloride and ferric chloride appears on the market under the trade name of *cotargit* and is alleged to contain still better styptic properties than cotarnine. It occurs as a ruby-red crystalline powder freely soluble in water.

Dose, three-fourths of a grain to three grains (0.048–0.2 Gm.).

CREOSOTI CARBONAS. U. S.

CREOSOTE CARBONATE Creosot. Carb.

(crē-o-sō'tī cär'bo-năs)

"A mixture of the carbonates of various constituents of creosote, chiefly guaiacol and creosol." *U. S.*

Creosote carbonate is known also by the trade names of *creosotal* and *creosotal-Heyden;* it is made by treating a solution of creosote and sodium hydroxide with carbonyl chloride. It is officially described as follows: "Creosote Carbonate is a clear, colorless or yellowish, viscid liquid, odorless, and tasteless, or having a slight odor and taste of creosote. On prolonged exposure to a low temperature, crystals of guaiacol carbonate separate, which redissolve on warming. Creosote Carbonate is insoluble in water and freely soluble in alcohol, soluble in petroleum benzin or fixed oils; it is miscible with chloroform or benzene. Specific gravity: 1.145 to 1.170 at 25° C. (77° F.). Heat about 0.5 mil of Creosote Carbonate for a few minutes with 10 mils of alcoholic potassium hydroxide T.S., and cool the mixture; a crystalline precipitate forms, which effervesces with acids. Incinerate about 1 Gm. of Creosote Carbonate; not more than 0.1 per cent. of ash remains. A saturated alcoholic solution of Creosote Carbonate is neutral to moistened litmus paper, and acquires only a yellow color on the addition of ferric chloride T.S. (*creosote*). Heat 25 mils of Creosote Carbonate on a water bath for half an hour with a solution of 15 Gm. of potassium hydroxide in 100 mils of alcohol, then evaporate the alcohol and mix the residue with an excess of hydrochloric acid; a liquid composed of two layers is obtained. On now separating the dark layer of creosote and shaking it with successive portions of 10 mils each of distilled water until the washings are only slightly acid to litmus, it has the boiling point given under *Creosotum;* the distillate, after separation of adhering water, responds to the remaining tests of identity and purity under *Creosotum.*" *U. S.*

Uses.—It is used in the treatment of *tuberculosis, pneumonia* and *bronchitis,* and is recommended as an intestinal antiseptic. It is reputed to be less irritant than is creosote. It is asserted to have an equally beneficial effect upon the bronchial mucosa and much less tendency to disturb digestion.

Dose, from five to thirty minims (0.3–1.8 mils) preferably in emulsion or capsules.

CREOSOTUM. U. S., Br.

CREOSOTE Creosot. [Creasote]

(crē-o-sō'tŭm)

"A mixture of phenols and phenol derivatives, chiefly guaiacol and creosol, obtained during the distillation of wood-tar. Preserve it in

tightly-stoppered, dark amber-colored bottles." *U. S.* "Creosote is a mixture of phenols which may be obtained by the distillation of beech tar, and consists chiefly of guaiacol and creosol." *Br.*

Creasotum, *Br.* (1885); Créosote du Goudron de Bois, *Fr. Cod.*; Créosote, *Fr.*; Kreosotum, *P. G.*; Kreosot, Buchenholstheerkreosot, *G.*; Creosoto, *It.*; Creosota, *Sp.*

This is a substance discovered in 1830 by Reichenbach in the products of the distillation of wood. This distillation of wood yields products very analogous to one fraction of the coal tar obtained by the destructive distillation of bituminous coal. This fraction is the heavy oil of coal tar, which comes over between 165° C. (329° F.) and 200° C. (392° F.): it is often called "*coal tar creosote,*" and contains a group of phenols, including carbolic acid, now known officially as *phenol,* C_6H_6O, boiling at a temperature not higher than 188° C. (370.4° F.), *cresylic acid,* or *cresol,* C_7H_8O, boiling at from 195° to 205° C. (383°–401° F.), and *xylenol,* or *dimethyl phenol,* $C_8H_{10}O$, boiling at 211° C. (411.8° F.). Wood tar is a complex mixture of phenoloid bodies. These are chiefly the acid methylic ethers of catechol (or pyrocatechin) and its homologues.

Preparation.—Creosote is obtained either from wood tar or from crude pyroligneous acid. When wood tar is used, it is distilled until it has attained the consistence of pitch. The distilled liquid divides itself into three layers, an aqueous between two oily layers. The inferior oily layer, which alone contains the creosote, is separated, and saturated with sodium carbonate to remove acetic acid. The liquid is allowed to rest, and the new oil which separates is decanted from it. This oil is distilled and yields products lighter than water, and a liquid heavier. The latter alone is preserved, and, after having been agitated repeatedly with weak phosphoric acid to neutralize ammonia, is allowed to remain at rest for some time. It is next washed until it is free from acidity, and then distilled with a fresh portion of weak phosphoric acid, care being taken to cohobate from time to time. The oily liquid thus rectified is colorless, and contains much creosote, but also a portion of light oil distillate. To separate the latter, the liquid is mixed with a solution of sodium hydroxide of the density 1.12, which dissolves the creosote, but not the light oil. The oil, which floats from its levity, is then separated, and the alkaline solution of the creosote is exposed to the air, until it becomes brown in consequence of the decomposition of a foreign matter, and is then saturated with sulphuric acid. This sets free the creosote, which is decanted and again distilled. The treatment by solution of soda, sulphuric acid, etc., is to be repeated until the creosote no longer becomes brown by exposure to the air, but only slightly reddish. It is then dissolved in a stronger solution of soda, and distilled again, and finally redistilled for the last time, rejecting the first portion which comes over, on account of its containing much water, and collecting the next portion; care being taken not to push the distillation too far. The product collected is creosote.

When creosote is extracted from pyroligneous acid, the first step is to dissolve sodium sulphate in the acid to saturation. The oil which separates and floats above is decanted, and, having been allowed to remain at rest for a few days, is saturated with potassium carbonate with the assistance of heat, and distilled with water. The oily liquid obtained is of a pale yellow color, and is to be treated as above detailed, in relation to the treatment of the corresponding oil obtained from wood tar.

Properties.—Creosote, when pure, is a colorless oleaginous liquid, of the consistence of oil of almonds, slightly greasy to the touch, volatilizable by heat, and having a caustic, burning taste, and a penetrating, disagreeable odor, like that of smoked meat, and analogous to, yet different from, that of phenol. As met with in commerce, it has frequently a brownish tinge. It burns with a sooty flame. Applied in a concentrated state to the skin, it corrugates and then destroys the cuticle, causing a white spot. On paper it leaves a greasy stain, which disappears in a few hours, or in ten minutes if heated to 100° C. (212° F.). It is a non-conductor of electricity, and refracts light strongly. It is devoid of acid or alkaline reaction. Mixed with water, it forms two layers, one consisting of one part of creosote and about eighty of water, the other, of one part of water and ten of creosote. It dissolves a large proportion of iodine and phosphorus, and a considerable amount of sulphur, especially when assisted by heat. Allen states that in Rhenish creosote guaiacol predominates, while a sample of Morson's creosote from "Stockholm tar," examined by him, boiled at about 217° C. (422.6° F.), and consisted chiefly of creosol.

The U. S. Pharm. describes creosote as "an almost colorless or yellowish, highly refractive, oily liquid, having a penetrating, smoky odor, and a burning, caustic taste; it does not readily become brown on exposure to light. Creosote is slightly soluble in water; it is miscible with alcohol, ether, or fixed or volatile oils. It is neutral or faintly acid to litmus. Specific gravity; not below 1.073 at 25° C. (77° F.). It begins to distil between 195° and 200° C. (383°–392° F.) and not less than 80 per cent. by volume distils between 200° and 220° C. (392°–428° F.). Creosote is inflammable, burning with a luminous, smoky flame. Add 1 drop of ferric chloride T.S. to 10 mils of a saturated aqueous solution of Creosote; the liquid develops a violet-blue color, which is very transient; it then clouds almost instantly, the color passing rapidly from a grayish-green to a muddy brown, with finally the formation of a brown precipitate. Mix equal volumes of Creosote and collodion in a dry test tube; no permanent coagulum is produced (*phenol and so-called "coal-tar creosote"*). Mix 4 mils of Creosote with 4 mils of glycerin; a clear mixture results, from which

a creosotic layer, equal to or greater in volume than the Creosote taken, separates on the addition of 1 mil of water (*"coal-tar creosote"*). Two mils of Creosote requires not less than 10 mils nor more than 18 mils of normal sodium hydroxide V.S. to produce a clear liquid. This liquid remains unclouded on diluting with 50 mils of distilled water (*hydrocarbons and bases*). Shake gently 1 mil of Creosote with 2 mils of petroleum benzin and 2 mils of freshly prepared barium hydroxide T.S., until a uniform mixture is produced. Upon complete separation three distinct layers are visible; a middle layer containing the Creosote, a benzin layer which is neither blue nor muddy, and an aqueous layer which does not acquire a red tint (*cœrulignol and some other high-boiling constituents of wood-tar*)." *U. S.*

The British Pharm. describes Creosote as "a colorless or pale yellow, highly refractive liquid, neutral or faintly acid to *litmus*. Freely soluble in *alcohol* (90 per cent.), in *ether*, in *chloroform*, and in *glacial acetic acid*. Specific gravity not below 1.080. Commences to boil below 200° C. (392° F.). Not less than 75 per cent. distils between 200° and 220° C. (392°–428° F.). A solution (1 in 100) in *alcohol* (90 per cent.) produces with a drop of *T. Sol. of ferric chloride* a green coloration rapidly changing to reddish brown. Dropped on white filter paper and exposed to a temperature of 100° C. (212° F.), it leaves no translucent stain (absence of less volatile liquids)." *Br.*

Creosote dissolves in ammonia. Strong nitric and sulphuric acids decompose it, the former giving rise to reddish vapors, the latter to a red color, which becomes black on the addition of more of the acid. Diluted nitric acid converts it into a brown resin, which, treated with ammonia, and then dissolved in boiling alcohol, gives, by evaporation, certain salts of ammonia, two of which contain new acids, discovered by Laurent. Hydrochloric acid produces no change in it. Morson, of London, gives a test based on the solvent power of glycerin over phenol, which is dissolved by it in all proportions, while pure creosote is insoluble or nearly so, and, consequently, if any liquid assumed to be creosote dissolves largely in glycerin, it probably consists in the whole, or in large part, of phenol. Subsequent experiments appear to show that this test succeeds best with Morson's creosote; beechwood creosote, although pure, sometimes mixes with glycerin without turbidity. Hager modified Morson's test by using a mixture of three parts absolute glycerin and one part water, and this is the basis of the present official test for distinguishing creosote from phenol. With this fairly good results are obtained, according to Allen. A still better test, according to John A. Clark, is an alcoholic solution of iron perchloride (*Tinct. Ferri Perchlor.*, Br.), which with an alcoholic solution of creosote produces a deep greenish-blue color, but with phenol a light brown. (*A. J. P.*, June, 1873, 269.) Creosote dissolves a large number of metallic salts, and reduces some of them to the metallic state, as, for example, silver nitrate and acetate. ***Froehde's reagent*** (a solution of 0.1 Gm. of sodium molybdate in 100 mils of concentrated sulphuric acid) is recommended by E. W. Davy as a distinguishing test for phenol. A drop or two of the doubtful liquid is to be agitated with two fluidrachms of distilled water, the whole filtered, and a drop or two of the test solution added. Pure creosote gives a brown or reddish-brown reaction on standing or slight warming, passing to a light yellowish-brown; with phenol, the brown passing to a maroon soon develops a more or less intense purple. The name creosote refers to its antiseptic properties, being derived from *κρέας, flesh,* and *σώζω, I preserve.*

Impurities and Adulterations.—Creosote is sometimes adulterated with rectified oil of tar and the fixed and volatile oils. All these substances are detected by strong acetic acid, which dissolves the creosote, and leaves them behind, floating above the creosote solution. Creosote from beechwood tar, however, is only partially dissolved by hot acetic acid of ordinary strength. Fixed oils are also discovered by a stain on paper not discharged by heat. Any trace of the matter which produces the brownish tinge is detected by the liquid becoming discolored by exposure to sunshine. Commercial creosote sometimes contains phenol and cresol, from coal tar; and, indeed, much of what has been sold for creosote was nothing more than impure phenol. (See *Phenol.*) It has been already stated that phenol strongly resembles creosote; but, as the effects of the two on the system are very different, it is highly desirable to be able to distinguish between them. Tests for this purpose have been given above, and, with those quoted from the Pharmacopœia, are sufficient for the purpose. The large doses in which creosote is now sometimes given makes the sale of the so-called "coal tar creosote" dangerous, for there would be a strong probability that a patient might be given a large dose of phenol with disastrous effects; all pharmaceutical manufacturers have ceased to label or market "coal tar creosote."

Uses.—The constitution of even genuine beechwood creosote varies very greatly in the proportion of guaiacol and creosol and in the amount of monophenols, and it would seem impossible to get under the name of creosote a fixed medicament. Nevertheless, for practical therapeutic purposes creosote is sufficiently constant in its composition, the physiological and therapeutic action of its various constituents being apparently so closely allied as to make variability in the proportion of these constituents of little importance.

The physiological effects produced by creosote have not been closely studied, but it would appear in many of its properties to resemble phenol. It is, however, much less poisonous and doses as high as thirty to sixty minims have been administered three times a day without harmful results. Freudenthal (*N. Y. M. R.*, April, 1892)

reports a case of a woman who took six hundred drops of creosote in a very short time the ingestion being followed almost immediately by unconsciousness with intense trismus, contracted immobile pupil, and general cyanosis, but recovery was made practically without administration of remedies; subsequently this same patient by graduating the dose was able to take five hundred drops daily without ill effect. Creosote is absorbed readily from the intestinal tract and its elimination is fairly rapid. It escapes chiefly through the kidneys in combination with sulphuric and glycuronic acids, but appears also to be in part eliminated by the lungs. Like phenol, it is, when locally applied, a paralyzant to the sensory nerves. Creosote is distinctly superior to phenol in its anti-bacterial properties, especially in dilute solutions. According to Guttmann (*Z. K. M.*, 1887, xiii) one part of creosote to three thousand completely inhibits the growth of bacteria.

Creosote was originally introduced in the treatment of *phthisis* with the idea that it would exercise an antiseptic action in the lungs. It is, however, extremely questionable whether the drug can reach the pulmonic tissue in sufficient concentration to have any direct antibacterial properties. Its beneficial influence in this disease can be ascribed to its stimulating effect upon the bronchial mucous membrane. For this action it is also a very valuable drug in the treatment of all types of *chronic bronchitis,* especially when there is over-secretion. In tubercular conditions it is generally necessary to give the drug in large doses. The secret of doing this successfully is to see that it is well diluted before ingestion. When being used freely it should never be given in the form of capsules but dissolved in either water or milk. A good rule is that the patient should take at least one-half an ounce of fluid for every drop of creosote; thus if ten minims were to be administered it would require five ounces of water. Perom has recommended the hypodermic administration in *phthisis.* For this purpose he uses a ten per cent. solution in oil of sweet almonds, two injections of eighty minims being given daily. Dor employed intratracheal injections of five per cent. solution in sterile olive oil.

Creosote is also a valuable gastro-intestinal antiseptic in the treatment of *fermentative gastritis* and *enteritis.* It is of service in *nausea* and *vomiting* for its local anesthetic action upon the gastric mucosa. Externally it has been used as a surgical disinfectant, but because of its stronger odor and greater cost is inferior to phenol, but when there is foul discharge, as in fetid *leukorrhea, otorrhea, empyema* or *gangrene,* is by many preferred. It is also useful in various *skin diseases,* both for its local anesthetic and antibacterial properties and has been recommended in *chilblains.* In capillary *hemorrhages* it has some power as a hemostatic but is not capable of arresting bleeding from large vessels. For this effect it has been used locally in the milder types of *uterine hemorrhage* and to stop the bleeding from *leech bites.* As a local application it may be employed in strengths of from one to ten per cent., according to the purpose for which it is used. On account of its local anesthetic and antiseptic influence, it is much employed by dentists for the obtunding of sensitive dentine and as an ingredient of pastes for the destruction of nerves. One or two drops of the pure substance must be carefully introduced into the hollow of the tooth on a little cotton, avoiding contact with the tongue or cheek. To render it effectual, the hollow of the tooth must be well cleansed before it is applied. A mixture of fifteen parts of creosote and ten of collodion is said to have a jelly-like consistence, and to be usefully applied to carious teeth, which it protects from the air; but, as pure creosote does not coagulate collodion, this remark applies properly to the impure phenol before stated to be commonly sold under the same name.

In an overdose creosote acts as a poison, producing giddiness, obscurity of vision, depressed action of the heart, convulsions, and coma. Medicinal treatment consists in evacuation of the poisons and administration of ammonia and other stimulants.

Under the name of *Vapor Creasoti* (*Inhalation of Creasote*), the British Pharmacopœia (1885) directed a preparation consisting of 12 minims of creosote and 8 fluidounces of boiling water, which were directed to be mixed in an inhaling apparatus, so arranged that the air should be made to pass through the solution, and then inhaled. It may be used in chronic inflammation of the air passages.

Mistura Creosoti, Br. Pharm., 1898, is no longer official, it was made by shaking 16 minims each of creosote and spirit of juniper with 1 fluidounce of syrup and enough distilled water to make 16 fluidounces of the mixture.

Dose, of creosote, five to ten minims (0.3–0.6 mil), which may be gradually increased.

CRESOL. U. S., Br.

CRESOL

(crēs′ōl)

"A mixture of isomeric cresols [C_7H_8O or $C_6H_4.CH_3.OH = 108.06$] obtained from coal tar. Preserve it in well-closed containers protected from light." *U. S.* "Cresol is a mixture of isomers of the formula C_7H_7OH, obtained from coal tar. Should be preserved in stoppered amber-colored bottles." *Br.*

Cresolum, Cresolum Purum; Cresylic Acid, Tricresol, Methylphenol, Oxytoluene; Cresol, *Fr.;* Enterol, Trikresoll Kresol, *G.*

Preparation.—Cresol was introduced into the U. S. P. (VIII and IX) mainly for use in making the official compound solution of cresol (*Liquor Cresolis Compositus*), an antiseptic solution well adapted for external uses because

of its miscibility with water. Crude carbolic acid is an impure form of cresol. Cresol is prepared from coal tar by collecting the distillates coming over between 140° C. (284° F.) and 220° C. (428° F.), and purifying these by treatment with solution of sodium hydroxide and hydrochloric acid.

Properties.—These are three isomeric cresols: *orthocresol,* melting at 31° C. (87.8° F.) and boiling at 188° C. (370.4° F.); *metacresol,* a liquid boiling at 201° C. (393.8° F.), but not solidifying even at -80° C. (-112° F.); and *paracresol,* forming colorless prisms, melting at 36° C. (96.8° F.) and boiling at 198° C. (388.4° F.). These cresols are all obtainable by fractional distillation from that portion of coal tar boiling between 190° and 210° C. (374°–410° F.). Cresol of the U. S. P. is "a colorless or yellowish to brown-yellow, highly refractive liquid, becoming darker or assuming a reddish tint with age and on exposure to light, and having a phenol-like, sometimes empyreumatic odor. One mil of Cresol dissolves in about 50 mils of water, usually forming a cloudy solution; it is miscible with alcohol, ether, benzene, petroleum benzin, or glycerin; it is dissolved by solutions of the fixed alkali hydroxides. Specific gravity: 1.030 to 1.038 at 25° C. (77° F.). Not less than 90 per cent. by volume of Cresol distils between 195° and 205° C. (383°–401° F.). A saturated aqueous solution of Cresol is neutral or slightly acid to litmus, and becomes blue-violet on the addition of ferric chloride T.S. A solution of 1 mil of Cresol in 60 mils of water is not more than slightly turbid (*hydrocarbons*)." *U. S.*

"A straw-colored liquid, becoming brown on keeping or on exposure to light. Soluble in 50 parts of *water,* the solution being neutral to *litmus;* freely soluble in *alcohol* (90 per cent.), in *ether,* in *chloroform,* in *glycerin,* and in the fixed and volatile oils. Specific gravity 1.040 to 1.050. When 0.5 millilitre is shaken with 300 millilitres of *water* and filtered, the filtrate gives a transient bluish color on the addition of *T. Sol. of ferric chloride.* Not less than 90 per cent. distils between 195° and 205° C. (383°–401° F.). 10 millilitres shaken with 10 millilitres of an aqueous solution (1 in 10) of *sodium hydroxide* form an almost clear liquid, from which no appreciable oily layer separates on standing for twenty-four hours (limit of hydrocarbon oils). 5 millilitres mixed with 5 millilitres of *glycerin* form a clear solution from which, on the addition of 5 millilitres of *water,* the cresol completely separates (absence of phenol)." *Br.*

Uses.—Cresol is used in medicine solely for its disinfectant properties. It far surpasses phenol in power, both as a germicide and antiseptic. Reed (*Trans. of the Association of Military Surgeons,* U. S., 1894, iv), finds that a one-half per cent. solution of cresol is sufficient to destroy the staphylococcus in less than twenty minutes; a one per cent. solution killed in thirty seconds and is equivalent to a four or five per cent. solution of phenol. Because of the sparing solubility of cresol in water it is generally employed in the form of a soapy solution or emulsion (see *Liquor Cresolis Compositus*). This solution retains the germicidal properties of the cresol, thus Fox (*Report of the Commissioner of Health of the State of Pennsylvania,* 1907, p. 123), finds that one per cent. of the official compound solution of cresol kills non-sporulating bacteria after two minutes' exposure and is superior to a one per cent. solution of phenol. McClintock (*U. S. Hygienic Laboratory Bulletin,* No. 82, April, 1912), gives the phenol coefficient of compound solution of cresol without organic matter 3.0, with organic matter 1.87. (For a list of some of the proprietary preparations of cresol, see p. 1347.) There is probably some difference in the germicidal powers of the various cresols so that the mixture which is known officially as cresol varies more or less in activity. According to Sage (*P. J.,* 1908, lxxx, p. 730) the compound solution of cresol of the British Pharmacopœia has a phenol coefficient varying from 1.25 to 3.75 according to the value of the cresylic acid from which it is made. Other authorities, however, do not find so great a variation.

The statement has been made that cresol is practically non-poisonous, but such is certainly incorrect. It is perhaps somewhat less toxic than phenol, but the difference is not very great, and there have been a number of fatal cases of cresol poisoning reported, as well from its use as a douche as from swallowing. The symptoms have been nausea and vomiting, general depression with a tendency towards stupor, gradually developing into coma, smoking albuminous urine, fall of bodily temperature, and collapse. Friedlander (*Th. M.,* 1907) recommends as antidotes large quantities of oil or the white of egg, which he believes act by preventing absorption; milk and watery fluids are to be avoided.

Cresol is used chiefly as a surgical disinfectant, both for the purposes of sterilizing instruments and as a wound dressing. For the former three to five per cent. of the compound solution should be employed, while for application to wounds one per cent. of the compound solution (representing one-half per cent. of cresol) is generally recommended. Cresol is also employed to a limited extent as a gastro-intestinal antiseptic in various types of *enteritis* and *gastritis.* For this purpose one or two minims (0.06–0.12 mil) of the cresol, well diluted, may be given.

Dose, from two to three minims (0.12–0.2 mil).

Off. Prep.—Liquor Cresolis Compositus, *U. S.* (*Br.*).

CRETA PRÆPARATA. U. S., Br.

PREPARED CHALK Cret. Præp. [Drop Chalk]

(crē'tą præ-pą-rā-tą)

"A native form of calcium carbonate freed from most of its impurities by elutriation and

containing, when dried to constant weight at 200° C. (392° F.), not less than 97 per cent. of $CaCO_3$ (100.07)." *U. S.* "Prepared Chalk is native calcium carbonate, freed from most of its impurities by elutriation." *Br.*

Creta Lævigata; Craie lavée, Craie préparée, *Fr.;* Präparirte Kreide, Schlämmkreide, *G.;* Creta preparada, *Sp.*

Preparation.—Calcium carbonate, in the extended meaning of the term, is the most abundant of simple minerals, constituting, according to its state of aggregation and other peculiarities, the different varieties of calcareous spar, common and shell limestone marble, marl, and chalk. It occurs also in the animal kingdom, forming the principal part of shells, and a small proportion of the bones of the higher orders of animals. It is present in small quantity in most natural waters, being held in solution as the bicarbonate, $Ca(HCO_3)_2$, by the carbon dioxide which they contain. In the waters of limestone districts it is a very common impregnation, and causes purging in those not accustomed to its use. In all such cases, boiling the water, by expelling the carbon dioxide, causes the carbonate to be deposited. It has been shown, however, that calcium carbonate is itself in a slight degree soluble in water; so that a small proportion remains in limestone water which has been long exposed to boiling. That the carbonate is not held in solution by free carbon dioxide is shown by the fact that lime water causes no precipitation. (*J. P. C.,* 4e sér., iii, 147.)

Chalk occurs abundantly in the south of England and the north of France. It exists in massive beds, and very frequently contains nodules of flint, and fossil remains of land and marine animals. According to F. V. Hayden, chalk beds identical with those of Europe extend for 400 miles along the Missouri River in Dakota. Chalk is an insipid, inodorous, insoluble, opaque, soft solid, generally white, but grayish-white when impure. It is rough to the touch, easily pulverized, and breaks with an earthy fracture. It soils the fingers, yields a white trace when drawn across an unyielding surface, and when applied to the tongue adheres slightly. Its sp. gr. varies from 2.3 to 2.6. It is never a perfectly pure calcium carbonate, but contains besides gritty silicious particles, small portions of alumina and ferric oxide. If pure, it is entirely soluble in hydrochloric acid, but usually a little silica is left. If this solution be not precipitated by ammonia, it is free from alumina and iron. Chalk, on account of the gritty particles which it contains, is unfit for medicinal use until it has been reduced to a very fine powder.

Having been thus very minutely divided, it is agitated with water, which upon standing a short time deposits the coarser particles, and, being then poured off, slowly lets fall the remainder in an impalpable state. The former part of the process is called *levigation* the latter *elutriation.* The soft mass which remains after the decanting of the clear liquor is made to fall upon an absorbent surface in small portions, which when dried have a conical shape. Practically, prepared chalk is made on the large scale from *whiting* by the manufacturer.

Properties.—"Prepared Chalk occurs as a white to grayish-white, very fine, amorphous powder, often formed into "conical drops"; odorless and tasteless; permanent in the air. Prepared Chalk is almost insoluble in water; insoluble in alcohol; decomposed and dissolved by diluted acetic, hydrochloric, or nitric acid, with copious effervescence. When a weighed amount of Prepared Chalk is dissolved in diluted hydrochloric acid not more than 2 per cent. of residue remains. Dissolve about 0.1 Gm. of Prepared Chalk in 5 mils of diluted acetic acid and filter the solution; the addition of ammonium oxalate T.S. to the filtrate yields a white precipitate, insoluble in acetic acid but soluble in hydrochloric acid. When heated to full redness, Prepared Chalk gradually loses carbon dioxide and is converted into calcium oxide.

"**Assay.**—Proceed as directed under *Calcii Carbonas Præcipitatus.* It shows, in the dried salt, not less than 97 per cent. of $CaCO_3$. Each gramme of dried Prepared Chalk corresponds to not less than 193.9 mils of tenth-normal oxalic acid V.S." *U. S.*

"White friable masses or a white powder. Yields the *reactions* characteristic of calcium and of carbonates. Yields not more than the slightest characteristic *reactions* for iron, aluminium, magnesium, phosphates, sulphates, or silica. *Arsenic limit* 5 parts per million. A solution of Prepared Chalk in *diluted acetic acid* yields no precipitate with *solution of potassium chromate* (absence of barium carbonate)." *Br.*

Uses.—This is the only form in which chalk is used in medicine. It is an excellent antacid; and, as the salts which it forms in the stomach and bowels, if not astringent, are at least not purgative, it is admirably adapted to *diarrhea* accompanied with acidity. It is also sometimes used in acidity of stomach attending *dyspepsia* and *gout,* when a laxative effect is to be avoided, and it is one of the best antidotes for oxalic acid. It has been employed as an application to *burns* and *ulcers,* which it moderately stimulates, while it absorbs the ichorous discharge and thus prevents it from irritating the diseased surface or the sound skin. It is given internally in the form of powder, or suspended in water by the intervention of gum arabic and sugar. (See *Mistura Cretæ.*) Lozenges of chalk were also official under the name of *Trochisci Cretæ* in the U. S. P. 1890. Prepared chalk is better fitted for chalk mixture than the precipitated calcium carbonate, in consequence of its more impalpable character and greater powers of adhesion.

Dose, from ten to forty grains (0.65–2.6 Gm.).

Off. Prep.—Mistura Cretæ, *U. S.* (from Compound Chalk Powder), *Br.;* Pulvis Cretæ Compositus, *U. S.;* Pulvis Cretæ Aromaticus, *Br., N. F.;* Pulvis Cretæ Aromaticus cum Opio (from Aromatic Chalk Powder), *Br., N. F.*

CUBEBA. U. S. (Br.)

CUBEB Cubeb. [Cubebs]

(cū-bē'bą)

"The dried, full-grown, unripe fruits of *Piper Cubeba* Linné filius (Fam. *Piperaceæ*), without the presence or admixture of more than 5 per cent. of stems or other foreign matter." *U. S.* "Cubebs are the dried full-grown unripe fruits of Piper Cubeba, *Linn. fil.*" *Br.*

Cubebæ Fructus, *Br.*; Fructus (s. Baccæ) Cubebæ, Piper Caudatum; Cubebs, Tailed Pepper; Cubèbe, Cubèbe ou Poivre à Queue, *Fr. Cod.*; Cubebæ, *P. G.*; Kubeben, *G.*; Pepe Cubebe, Cubebe, *It.*; Cubeba, *Sp.*; Kebabeh, *Ar.*

Piper Cubeba is a climbing perennial plant, with a smooth, flexuous, jointed stem, and entire, petiolate, oblong or ovate-oblong, acuminate leaves, rounded or obliquely cordate at the base, strongly nerved, coriaceous, and very smooth. The flowers are diœcious and in spikes, with peduncles about as long as the petioles. The fruit is a globose, pedicelled drupe. This species of Piper is a native of Java, Penang, and probably other parts of the East Indies. It is extensively grown in the coffee plantations, supported by the trees which are used for shade, and has been introduced into Ceylon. The dried unripe fruit is the official portion. Our knowledge of the false cubeb of commerce up to 1894 was epitomized in the 17th edition of the U. S. D., p. 457. To this account the reader is referred for historical details. (See also *U. S. D.*, 19th ed., p. 410.)

Properties.—Cubeb is officially described as follows: "Upper portion globular, from 3 to 6 mm. in diameter, with a straight, slender stem-like portion, from 5 to 7 mm. in length; pericarp externally grayish, brownish, or bluish-black; coarsely reticulate; about 0.3 mm. in thickness, easily cut, 1-locular, 1-seeded; the immature seed attached at the base of the pericarp; odor aromatic, characteristic; taste strongly aromatic and pungent. Under the microscope, sections of Cubeb show an epidermal layer of tabular cells with thickened, undulate outer walls, the contents being olive-green; 1 or 2 rows of parenchyma cells, the contents resembling those of the epidermal cells; a continuous layer of radiately elongated, thick-walled stone cells having numerous pores; a few layers of collapsed cells near which may occur an occasional small group of bast-fibers; a middle layer of 10 rows of cells composed chiefly of parenchyma, scattered among which are numerous secretions cells containing a volatile oil and occasionally crystals in the form of short rods, the contents of the secretion cells being colored a deep crimson upon the addition of sulphuric acid; an endocarp of small, somewhat isodiametric or polygonal stone cells with very thick porous walls; seed-coat of several rows of reddish-brown, tangentially elongated, more or less collapsed cells; perisperm of numerous thin-walled parenchyma, the cells being more or less polygonal in shape and containing either small compound starch grains, or globules of a fixed oil or occasionally a crystal of calcium oxalate. The powder is light brown to blackish-brown, consisting of a more or less even distribution of starch-bearing cells of the perisperm and fragments of the pericarp with stone cells; starch grains numerous, single or compound, from 0.002 to 0.012 mm. in diameter; stone cells numerous in palisade-like groups, in surface view rounded or polygonal with rather prominent dark lumina and yellowish porous walls; secretion cells with a yellowish, oily content, becoming reddish on the addition of sulphuric acid; fragments of stalk few, with spiral tracheæ and groups of sclerenchymatous fibers from 0.05 to 1 mm. in length with blunt, rounded, or very much attenuated ends, the walls strongly lignified and with numerous oblique pores. Cubeb yields not less than 10 per cent. of volatile extractive, soluble in ether (see Part III, Test No. 12). Cubeb yields not more than 8 per cent. of ash." *U. S.*

"Nearly globular, about four millimetres in diameter, greyish-brown or nearly black. Pericarp reticulately wrinkled, thin, brittle, and abruptly prolonged at the base into a slender, rounded stalk about one and a half times as long as the globular portion. Seed almost spherical, sometimes much shrivelled, attached by the base. In the transverse section of the pericarp two layers of sclerenchymatous cells, one near the outer, the other near the inner surface, those of the latter being radially elongated and usually arranged in a single row. Strong, aromatic, and characteristic odor; taste warm, aromatic, and somewhat bitter. When 2 grammes of powdered Cubebs are macerated with 20 millilitres of *ether* for twenty-four hours, and shaken occasionally, 10 millilitres of the clear ethereal solution, allowed to evaporate in a flat-bottomed dish, yield a residue which, dried for one hour in a desiccator over *sulphuric acid*, weighs not less than 0.200 gramme. Crushed Cubebs impart a crimson color to *sulphuric acid*. Ash not more than 8 per cent." *Br.*

Commercial cubebs are not infrequently admixed with and entirely substituted by other fruits, some of which contain volatile oils which possess very different properties from the genuine oil of cubeb, being in some instances highly toxic. Hartwich (*Arch. d. Pharm.*, 1898, Heft 3; also p. 172) gives the following classification for the identification of spurious fruits:

I. *Fruits of the Piperaceæ having slender stalks.*

A. STONE CELLS IN EPICARP, ENDOCARP AND DISTRIBUTED IN THE MESOCARP:

Piper ribesioides Wallich (identical with *Padang Cubeb*). Fruits not colored red with sulphuric acid.

B. STONE CELLS ONLY PRESENT IN THE EPICARP AND ENDOCARP:

(*a*) Stone cells of the endocarp radially elongated.

Piper Cubeba L.f. Seed attached only at the base of the pericarp.

α Rinoe Katoentjor, the official variety, which is colored red with sulphuric acid.

β *Rinoe badak,* distinguished by not being colored red with sulphuric acid.

(*b*) Stone cells of the endocarp of isodiametric form.

Piper crassipes Korthals. Sections not colored red with sulphuric acid.

(*c*) Stone cells of the endocarp thickened like a horseshoe.

Piper à court pédicelle. Origin unknown.

C. STONE CELLS PRESENT ONLY IN THE EPICARP:

(*a*) Fruit with stem 3 cm. in length, the stem-like portion being alone 17 mm. long.

Piper mollissimum Blume (*Keboe Cubeb. Karbauw berries*) sections not colored red with sulphuric acid.

(*b*) The fruits and stems much smaller, but distinguished by having radially elongated stone cells.

Piper venosum DC. colored red with sulphuric acid.

D. STONE CELLS ABSENT IN THE PERICARP:

(*a*) African varieties:

1. Fruit without stem 5 to 6 mm. long, stem-like portion equally long.

α *Piper clussi* DC., sections colored red with sulphuric acid.

β *Piper guineense* Schum. sections not colored red with sulphuric acid.

2. Fruits 4 mm. long, 2 to 3 mm. thick and stems 6 mm. long.

Piper borbonense DC. (*Cubèbe du pays*) sections not colored red with sulphuric acid.

(*b*) Indian varieties: None of which are colored red with sulphuric acid.

α Stems flattened.

Piper Lowong Blume. Secretion cells colored bluish-green with sulphuric acid.

Ceylon pepper. Secretion cells colored yellow with sulphuric acid.

β Stem-like portion cylindrical.

Piper canium Blume and *P. phyllostitum* DC.

II. *Fruits of the Piperaceæ without stalks.*

A. STONE CELLS PRESENT IN EPICARP AND ENDOCARP:

1. *Piper nigrum* L. Stone cells of epicarp radially elongated and sections colored red with sulphuric acid.

2. *Cubèbe de Jaba sauvage.* Stone cells of the epicarp not radially elongated.

B. STONE CELLS ONLY IN THE EPICARP:

Dangdang boeroeng. A fruit obtained from Java, the origin of which is unknown.

C. STONE CELLS ABSENT IN PERICARP.

Cubeb from Bangil, origin unknown. Sections at first colored red with sulphuric acid, then becoming brown.

III. *Fruits obtained from plants belonging to other families than the Piperaceæ.*

1. *Xanthoxylum Budrunga* Wall. (*Fagara Budrunga* Roxb.) (*Rutaceæ*).

2. *Bridelia tomentosa* Bl. (*Euphorbiaceæ*).

3. *Tetranthera citrata* N. v. Esenbeck (*Litsea citrata* Bl.) (*Lauraceæ*).

4. *Daphnidium Cubeba* Nees. (*Lauraceæ*).

5. *Pericampylus incanus* Miers. (*Menispermaceæ*).

6. *Xylopia frutescens* Gaertner. (*Anonaceæ*).

7. *Helicteres hirsuta* Bl. (*Steruliaceæ*).

8. *Grewia tomentosa* Juss. (*Tiliaceæ*).

Constituents.—The most obvious constituent of cubeb is the volatile oil, the proportion of which yielded by the drug varies from 4 to 13 per cent. It is, as shown by Oglialoro, a mixture of a terpene, $C_{10}H_{16}$, boiling at 158° to 163° C. (316.4°–325.4° F.), which is present in very small amount, and is probably pinene or camphene, some dipentene, and two oils of the formula $C_{15}H_{24}$, boiling at 262° to 265° C. (503.6°–509° F.). One of these, known as *cadinene,* is strongly lævogyrate, and yields a crystallized compound having the formula, $C_{15}H_{24}2HCl$, and melting at 118° C. (244.4° F.), while the other is less lævogyrate, and does not combine with HCl.

The oil distilled from old cubeb on cooling at length deposits large transparent inodorous octahedra of *camphor of cubeb,* $C_{15}H_{26}O$. E. Schmidt found that this camphor melts at 66.5° C. (152° F.); simply by standing over sulphuric acid, more rapidly on heating, it gave up water and passed into that fraction of cubeb oil which boils at 260° C. (500° F.), of which it is, therefore, simply the hydroxide. Another constituent of cubeb is *cubebin.* This is an inodorous substance, crystallizing in small needles or scales, melting at 125° C. (257° F.), having a bitter taste in alcoholic solution, it dissolves freely in boiling alcohol, but deposits on cooling, and is abundantly soluble in chloroform. Its composition, according to Weidel (1877), is $C_{10}H_{10}O_3$, and its structural formula,

$$C_6H_3\begin{cases} O \\ O>CH_2 \\ C_3H_4OH \end{cases},$$

shows a close relationship to safrol, $C_6H_3\begin{cases} O \\ O>CH_2 \\ C_3H_5 \end{cases}$. Fused with potassium hydroxide it yields proto-catechuic acid. The resin extracted from cubeb consists of an indifferent portion, nearly 3 per cent., and of *cubebic acid,* $C_{13}H_{14}O_7$, amounting to about 1 per cent. (*Pharmacographia,* 2d ed., p. 587.)

The formula of cubebic acid as just given is that of Schmidt. Schultze (*Jahresbericht,* 1873, p. 863), on the other hand, gives to it the formula $C_{26}H_{30}O_7 + H_2O$. According to Capitaine and Soubeiran, *cubebin* is best obtained by expressing cubeb from which the oil has been distilled, preparing from the marc an alcoholic extract, treating this with a solution of potassium hydroxide, washing the residue with water, and purifying it by repeated crystallizations in alcohol. In the official oleoresin of cubeb a deposit takes place consisting chiefly of cubebin, which may be obtained by washing the deposit with a small quantity of cold alcohol to remove adhering resin and oil, and then dissolving repeatedly in boiling alcohol, and crystallizing until the

product is white. E. Schaer calls attention to the similarity in reaction between cubebin and veratrine, aconitine, morphine, and digitalin. (*A. Pharm.*, 1887, p. 531.) The volatile oil is official. (See *Oleum Cubebæ.*) By practical trial Bernatzik has satisfied himself that the peculiar virtues of cubeb as a remedy in *gonorrhea* depend not on the cubebin or the volatile oil, but on the cubebic acid. When the ethereal extract of cubeb is deprived of its volatile oil by evaporation on a water bath, and of cubebin and wax by deposition, a soft resin is left, the *cubebic acid* of Bernatzik, in which, according to F. V. Heydenreich, who experimented with it as a physiological agent, the diuretic properties reside, the cubebin being without apparent effect, and the volatile oil, though stimulant and carminative, having no diuretic action. The soft resin, which was of the consistence of honey, of a dark olive-green color, and some remaining odor of cubeb, when taken in the dose of ten grains every two hours for six hours, acted as a laxative, and gave the urine a peculiar odor, without increasing its quantity; but in the dose of a drachm, once repeated at an interval of three hours, while it produced the same effects as the smaller dose, it considerably augmented the urine. In still larger doses it produced decided irritation of the urinary passages. (*A. J. P.*, Jan., 1868.) Heydenreich's experiments are confirmatory of Bernatzik's conclusion as to the peculiar active principles of cubeb. Cubeb gradually deteriorates by age, and in powder becomes rapidly weaker, in consequence of the escape of its volatile oil. It should be kept whole, and pulverized when dispensed. The powder is said to be sometimes adulterated with that of pimenta.

Uses.—Cubeb is generally stimulant, with a special direction to the urinary organs. In considerable quantities it excites the circulation, increases the heat of the body, and sometimes occasions headache and giddiness. At the same time it frequently produces an augmented flow of the urine, to which it imparts a peculiar odor. Among its effects are also occasionally nausea and moderate purging, and it is said to cause a sense of coolness in the rectum during the passage of the fæces. We have no evidence that it was known to the ancients. It was probably first brought into Europe by the Arabians, and was formerly employed for similar purposes as black pepper, but it was found much less powerful and fell into disuse. In India it has long been used in *gonorrhea* and *gleet*, and as a grateful stomachic and carminative in disorders of the digestive organs, and it is at present very frequently given both in this country and in Europe in *gonorrhea*, after the subsidence of the first active inflammatory symptoms. It has been given also in *leucorrhea*, *cystorrhea*, the *urethritis* of women and female children, *abscess of the prostate gland*, *piles*, and *chronic bronchitis*. In connection with copaiba it has been especially recommended in affections of the neck of the bladder and the prostatic portion of the urethra. It is best administered in powder, of which the dose in *gonorrhea* is from one to three drachms (3.9–11.6 Gm.) three or four times a day. The volatile oil may be substituted, in the dose of ten or twelve minims (0.6–0.7 mil), suspended in water by means of sugar, although the oleoresin is generally preferred. (See *Oleoresina Cubebæ.*) An infusion, made in the proportion of an ounce of cubeb to a pint of water, has been employed as an injection in discharges from the vagina.

Dose, of powdered cubeb, ten grains to one drachm (0.65–3.9 Gm.).

CUPRI SULPHAS. U. S., Br.

COPPER SULPHATE Cupr. Sulph. [Cupric Sulphate]

(cū'prī sŭl'phăs)

"It contains not less than 62.97 per cent. nor more than 66.79 per cent. of anhydrous copper sulphate corresponding to not less than 98.5 per cent. of the crystallized salt [$CuSO_4 + 5H_2O = 249.72$]. Preserve it in well-closed containers." *U. S.* "Copper Sulphate, $CuSO_4,5H_2O$, may be obtained by the interaction of sulphuric acid, copper or copper oxide, and water." *Br.*

Cuprum Vitriolatum; Blue Vitriol, Roman Vitriol, Blue Stone; Sulfate de Cuivre, *Fr. Cod.;* Vitriol bleu, Couperose bleu, *Fr.;* Cuprum Sulfuricum, *P.G.;* Schwefelsaures Kupfer, Kupfersulfat, Kupfervitriol, Blauervitriol, Blauer Galitzenstein, *G.;* Solfato di rame, Vitriolo di rame, *It.;* Sulfato cuprico, Vitrolo azul, *Sp.*

Preparation.—Copper sulphate occasionally exists in nature, in solution in the water which flows through copper mines. In this case the salt is procured by merely evaporating the waters which naturally contain it. Another method of obtaining it is to roast the native sulphide in a reverberatory furnace, whereby it is made to pass, by absorbing oxygen, into the state of sulphate. Too high a temperature must be avoided during the roasting process to avoid the production of hard masses from which the copper is extracted with great difficulty. The roasted mass is lixiviated, and the solution obtained evaporated that crystals may form. The salt procured by either of these methods contains a little ferric sulphate, from which it may be freed by adding either an excess of cuprous oxide, which precipitates ferric oxide, or recently precipitated copper subcarbonate, which causes the deposition of the iron as a carbonate. (*A. J. P.*, xxxiv, 507.) A third method is to dissolve copper scales to saturation in sulphuric acid contained in a wooden vessel lined with

sheet lead. The scales consist of metallic copper mixed with oxide, and are produced in the process for annealing sheet copper.

Most of the copper sulphate produced at present is obtained as a by-product by the gold, silver, and copper refiners. The production of copper sulphate in the United States is very large, and there is a considerable exportation; this amounted in 1916 to 17,978,242 pounds.

In the U. S. Pharmacopœia copper sulphate is presumed to be obtained pure from the manufacturer; the British Pharmacopœia suggests the method in which it may be prepared, without entering into the details of the process. The German Pharmacopœia has two kinds official, *Cuprum sulfuricum,* which corresponds with the former *Cuprum sulfuricum purum,* and *Cuprum sulfuricum crudum,* or commercial sulphate.

Properties.—Copper sulphate "occurs as deep blue, triclinic crystals, or as blue, granular powder; odorless, of a nauseous, metallic taste; slowly efflorescent in dry air. One Gm. of Copper Sulphate dissolves in 2.5 mils of water, 500 mils of alcohol, and in 2.8 mils of glycerin at 25° C. (77° F.); also in 0.5 mil of boiling water. An aqueous solution of the salt (1 in 20) has a blue color, and is acid to litmus. When heated to 30° C. (86° F.) the salt loses part of its water of crystallization and is converted into a pale blue, amorphous powder. More water is lost at 100° C. (212° F.), and finally at 200° C. (392° F.) a white, anhydrous powder remains. At a still higher temperature, sulphur dioxide and oxygen are given off, and a residue of black cupric oxide remains. Place a drop of an aqueous solution of the salt (1 in 20) on a bright piece of iron; a red film of metallic copper is deposited. Barium chloride T.S. produces a white precipitate, insoluble in hydrochloric acid, in an aqueous solution of the salt (1 in 10). Add ammonia water to an aqueous solution of Copper Sulphate (1 in 10), drop by drop; a pale blue precipitate of cupric hydroxide forms, which redissolves in an excess of ammonia water, producing a deep azure-blue solution. Dissolve 1 Gm. of the salt in 50 mils of distilled water, add 1 mil of diluted hydrochloric acid and pass hydrogen sulphide gas through the solution until all of the copper is precipitated. Upon evaporating the filtrate and igniting, the weight of the residue does not exceed 0.003 Gm. (*other metals*).

"**Assay.**—Dissolve about 1 Gm. of Copper Sulphate, accurately weighed, in 50 mils of distilled water and add 4 mils of acetic acid and 3 Gm. of potassium iodide and titrate the liberated iodine with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 62.97 per cent. nor more than 66.79 per cent. of $CuSO_4$.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.015964 Gm. of $CuSO_4$. Each gramme of Copper Sulphate corresponds to not less than 39.44 mils nor more than 41.83 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

"Blue triclinic prisms. Soluble in 3.5 parts of *water,* very soluble in *glycerin,* almost insoluble in *alcohol* (90 per cent.). The aqueous solution is acid to *litmus.* Yields the *reactions* characteristic of copper and of sulphates. Yields no characteristic *reactions* for lead, zinc or aluminium. *Arsenic limit* 10 parts per million. Contains not more than 0.1 per cent. of iron, calculated as iron, Fe, when tested by the following process:—Dissolve 5 grammes in 25 millilitres of *water,* add 2 millilitres of *nitric acid,* heat to boiling, cool, and add *strong solution of ammonia* until the precipitate which first forms is redissolved and the liquid has a distinct odor of ammonia. Filter. Wash the filter paper thoroughly with *water* made alkaline with *solution of ammonia,* redissolve in *hydrochloric acid* any precipitate that has been collected, reprecipitate with *solution of ammonia,* collect, wash, dry, ignite, and weigh the residue. It weighs not more than 0.007 gramme." *Br.*

When heated, copper sulphate first melts in its water of crystallization, and then dries and becomes white. If the heat is increased, it next undergoes the igneous fusion, and finally, at a high temperature, loses its acid, cupric oxide being left. Four of the molecules of water of crystallization can be driven off at 100° C. (212° F.); but the fifth goes off only at a temperature of from 220° C. (428° F.) to 240° C. (464° F.), when the anhydrous salt remains. Potassium hydroxide, sodium hydroxide, and ammonia throw down from it a bluish-white precipitate of hydrated cupric oxide, which is immediately dissolved by an excess of the last mentioned alkali, forming a rich deep blue solution, called *aqua sappharina.* It is decomposed by the alkaline carbonates, and by borax, lead acetate and subacetate, ferric acetate, silver nitrate, mercuric chloride, potassium tartrate, and calcium chloride, and it is precipitated by all astringent vegetable infusions. If it becomes very green on the surface by the action of the air, it contains ferric oxide. This oxide may also be detected by ammonia, which will throw it down along with the copper oxide, without taking it up when added in excess. When copper sulphate is obtained from the *dipping liquid* of manufacturers of brass or German silver ware, it is always contaminated with zinc sulphate, as pointed out by S Piesse. This liquid is at first a mixture of sulphuric and nitric acids, but becomes, at last, nearly saturated with copper. When zinc is present in copper sulphate, it will be taken up by solution of potassium hydroxide added in excess, from which it may be thrown down, after filtration, in white flocks, by a solution of bicarbonated alkali.

Copper sulphate is incompatible with alkalies and liberates iodine from iodides.

Uses.—Copper sulphate is irritant or mildly escharotic, and when in diluted solution, stimulant and astringent. At one time it was given in *epilepsy* and other nervous diseases, but at present it is never used internally, except for

its influence upon the gastro-intestinal mucous membrane. In *chronic diarrhea* with ulceration it is often a useful remedy. In doses of 5 grains it acts as a powerful, prompt emetic, without causing general depression or much nausea, but is too irritant to be used freely; it is useful as an emetic in *phosphorus poisoning* because it not only empties the stomach but acts also as a chemical antidote to the phosphorus. Externally it is employed in solution as a stimulant to ill-conditioned *ulcers,* as an escharotic for destroying *warts,* fungous *granulations,* and callous edges, and as a styptic to bleeding surfaces. It is found, in not a few instances, to promote the cicatrization of ulcers, and is not infrequently employed, with that view, as a wash for *chancres.* Bevan (*S. M.,* 1905, p. 558) has used copper sulphate successfully in *actinomycosis.* He gave from one to three grains (0.065–0.2 Gm.) daily and applied a 1 per cent. solution to the ulcerated area.

Copper sulphate is highly poisonous to certain of the lower forms of vegetable life, thus it has been found serviceable for destroying the algæ in ponds. While in general its antibacterial properties are not very powerful it seems to be especially poisonous towards the *Bacillus typhosus,* Gildersleeve (*A. J. M. S.,* 1905, cxxxix, p. 757) having shown that as little as one part to a million is sufficient to destroy this bacterium in a period of three hours. It was at one time suggested as a means for purifying drinking water but is not practically available because the presence of various impurities destroys its action.

The preparation called *cuprum aluminatum* (*lapis divinus—pierre divine*) is made, according to the French Codex, by mixing, in powder, three ounces, each, of copper sulphate, potassium nitrate, and alum, heating the mixture in a crucible, so as to produce aqueous fusion, then mixing in a drachm of powdered camphor, and, finally, pouring out the whole on an oiled stone to congeal. The mass, when cold, is broken into pieces, and kept in a well-stoppered bottle. It is often desirable to employ copper sulphate, as a caustic, in the form of pencil. Its tendency to effloresce interferes with its use in this way in the pure state. Llovet recommends for the purpose a mixture of one part of potassa-alum and two of copper sulphate, which are to be first powdered, and then gradually melted together in a porcelain vessel, and poured into moulds made of bronze. (*Gaz. des Hôp.,* Juillet 28, 1863.) Another mode of preparing *pencils of copper sulphate* is to rub briskly together four parts of that salt and one of borax, and to mould the plastic mass which results, into the desired form. (*A. J. P.,* March, 1864, p. 106.) An elongated cone is the best form, made by selecting suitable crystals and turning them in a lathe to the desired form; or they may be made by filing the crystals, and finishing with sand-paper.

Dose, of copper sulphate, as an astringent, one-fourth of a grain (0.016 Gm.); as an emetic, five grains (0.32 Gm.), repeated in fifteen minutes if necessary, but not oftener than once. As a stimulant wash, the solution may be made of the strength of two, four, or eight grains to the fluidounce of water. For its effects as a poison, see *Cuprum.*

CUPRUM.

COPPER

(cū'prŭm)

Cu = 63.57

"Fine Copper wire, about No. 25 wire gauge or about 0.02 inch." *Br.,* 1885.

Cupreum Filum: Fil de Cuivre, Cuivre, *Fr.;* Kupfer, Kupferdraht, *G.;* Rame, *It.;* Cobre, *Sp.*

This metal is very generally diffused in nature, and exists principally in four states; as native copper, as an oxide, as a sulphide, and as a salt. Its principal native salts are the silicate, carbonate, arsenate, and phosphate. In the United States it occurs in various localities, but especially in the neighborhood of Lake Superior, in Montana, Arizona, Alaska and East Tennessee. The principal producing copper mines of Europe are those of Spain and Portugal and of Mansfeld in Germany. Chili and Japan are also relatively large producers at present.

The total production of copper in the United States has increased very rapidly in recent years, and now is more than two-thirds of the world's annual production. It was for 1915, 1,424,649,565 pounds, and in 1916 nearly 2,000,000,000 pounds. The three most productive states are Arizona, Montana, and Michigan, in the order named. The consumption of copper in the United States for 1915 was 1,043,461,982 pounds, and exports for the same year 681,953,301 pounds.

Properties.—Copper is a brilliant, sonorous metal, of a reddish color, and very ductile, malleable, and tenacious. It has a slightly nauseous taste, and emits a disagreeable odor when rubbed. Its texture is granular, and its fracture hackly. Its sp. gr. is 8.92 to 8.95, and its fusing point 1080° C. (1976° F.). Exposed to the air it undergoes a slight tarnish. Its combinations are numerous and important. With oxygen it forms two well characterized oxides, a red suboxide, better known as *cuprous* oxide, Cu_2O, and a black oxide, known as *cupric* oxide, CuO. While a cuprous chloride, iodide, and sulphide are known, it is the cupric oxide chiefly that unites with the several acids to form the copper salts. With metals copper forms numerous alloys, of which that with zinc, called *brass,* and that with tin, called *bronze,* are the most useful. *Bell metal, gun metal,* and *German silver* are other alloys in frequent use in which copper is the predominating constituent.

Characteristics.—Copper is recognized by its

color, and the effects of tests on its solution in nitric acid. This solution, with potassium hydroxide, sodium hydroxide, and ammonia, yields a blue precipitate, soluble in excess of the latter alkali, with which it forms a deep azure-blue liquid. Potassium ferrocyanide occasions a brown precipitate of copper ferrocyanide, and a bright plate of iron immersed in the solution immediately becomes covered with a film of metallic copper. Thoms (*Zeit. An. Chem.*, 94, 464) asserts that if to a solution, too dilute to give a sensible reaction with potassium ferrocyanide, be added a solution of potassium iodide, a yellow coloration is produced which becomes violet with starch paste. This test, in absence of deoxidizing agents, will show as little as 1 to 500,000. Potassium ferrocyanide is a very delicate test for minute portions of copper in solution. Another test, proposed by Verguin, is to precipitate the copper in the metallic state on platinum by electrochemical action. For this purpose a drop of the (acid) liquid to be examined is placed on a slip of platinum foil, and a slip of bright iron is brought in contact with the platinum and the liquid. If copper be present it will be instantly precipitated on the surface of the platinum. Copper compounds when present in food or drug products in appreciable amounts may be detected by the simple test of immersing a bright piece of steel or iron (as a knitting needle, spatula) into the material which has been brought to a pasty condition and acidulated with hydrochloric acid. The copper will be deposited upon the iron or steel in the form of a very thin easily perceptible film.

Action on the Animal Economy.—Copper in its pure state is nearly inert, but in combination it is highly deleterious. Nevertheless, a minute portion of the metal has been found in the human body. Wackenroder found copper in the blood of man, but does not consider it a constant and normal constituent. He also detected this metal in the blood of domestic animals living on a mixed diet, but not in their blood when nourished on vegetable food only. It has been found in the feathers of certain birds, as of a grass-green paroquet from Australia, which is said to frequent districts of the country where copper is found.

The soluble combinations of copper, when taken in poisonous doses, produce a coppery taste in the mouth; nausea and vomiting; violent pain in the stomach and bowels; frequent black and bloody stools; small, irregular, sharp, and frequent pulse; faintings; burning thirst; difficulty of breathing; cold sweats; paucity of urine, and burning pain in voiding it; violent headache; cramps, convulsions, and finally death. The best antidote is potassium ferrocyanide, given freely, which forms with the poison the insoluble copper ferrocyanide. Soap and alkalies are also antidotal. Before the antidote can be procured, large quantities of albuminous substance of milk or white of eggs should be given mixed with water, which act favorably by forming copper caseinate and copper albuminate, respectively, but these compounds should be evacuated as soon as possible by vomiting and purging. Should vomiting not take place, the stomach tube may be employed. The symptoms of slow poisoning by copper are, according to Corrigan, of Dublin, a cachetic appearance, emaciation, loss of muscular strength, colicky pains, cough without physical signs, and retraction of the gum, with a persistent purple edge, quite distinct from the blue edge produced by lead. (*Braithwaite's Retrospect*, Am. ed., xxx, 303.) But there is much doubt whether these symptoms can be produced by the metal.

In medico-legal examinations, where cuprous poisoning is suspected, Orfila recommends that the viscera be boiled in distilled water for an hour, and that the matter obtained by evaporating the filtered decoction to dryness be carbonized by nitric acid. The carbonized product will contain the copper. By proceeding in this way there is no risk of obtaining the copper which may happen to pre-exist in the animal tissues. This method of search is preferable to that of examining the contents of the stomach and intestines, from which copper may be absent, while it may have penetrated the different organs by absorption, especially the abdominal viscera.

Vessels of copper which are not coated with tin should not be used in pharmaceutical or culinary operations, for, although the metal uncombined is inert, yet the risk is great that the vessels may be acted on and a poisonous salt formed.

CUSSO. Br.

KOUSSO [Brayera]

(cūs'sō)

"Kousso consists of the dried panicles of pistillate flowers of Brayera anthelmintica, *Kunth.*" *Br.* "The dried panicles of the pistillate flowers of *Hagenia abyssinica* (Bruce) Gmelin (Fam. *Rosaceæ*), without the presence of more than 10 per cent. of the staminate flowers, other parts of the tree, or other foreign matter. Reject any portions of the stems over 3 mm. in diameter and any binding material, before the drug is powdered or used." *N. F.*

Brayera, *N. F.*; Kooso; Kusso; Cousso, *Fr. Cod.*; Kousso, *Fr.*; Flores Koso, *P. G.*; Kosoblüthen, Koso, Kusso, Cusso, *G.*; Kousso, Cosso, *It.*; Couso, *Sp.*

Kousso was dropped from the U. S. P. IX but has been introduced into the N. F. IV and is retained in the Br. Pharm., 1914.

Hagenia abyssinica Willd. (Syn. *Brayera anthelmintica* Kunth) is a beautiful tree about twenty feet high, growing on the table-land of Abyssinia, at an elevation of from three thousand to eight thousand feet. The branches exhibit circular cicatrices, left by the fallen leaves. The latter are crowded near the ends of the branches, are large, pinnate, sheathing at the base, with opposite, lanceolate, serrate, leaflets, villose at the margin, and nerved beneath. The

unisexual flowers are tinged with purple, pedicelled, with an involucre of four roundish, oblong, obtuse, membranous bracts, and are arranged in fours, upon hairy, flexuous, bracteate peduncles, with alternate branches. They are small and of a greenish color, becoming purple. These and the unripe fruit are the parts of the plant employed. The petals are apt to be wanting in the dried flowers. They are brought from Abyssinia packed in boxes, reaching Europe chiefly by way of Aden and Bombay. The Abyssinian name of the medicine has been variously spelled by European writers kosso, koosso, cusso, cosso, etc. The fruit of the tree is said to be used as an anthelmintic in Abyssinia, but Dragendorff failed to detect any active principle in it. It is stated that in Abyssinia, honey gathered directly after the flowering season from beehives in gardens planted with kousso plants, is used in doses of a teaspoonful as a very effective tenicide.

Properties.—The dried flowers are in unbroken though compressed clusters. The male flowers are usually collected, so that ordinarily the general color of the mass is greenish-yellow or light brown; sometimes the female flowers constitute the bulk of the drug, which then has a distinct reddish tint, and is often known in commerce as *red kousso*. In accordance with our Pharmacopœia, this commercial variety should alone be used. The male flowers are often found mixed with the female flowers, when loose (not in bundles), as high as 12 per cent. of this adulteration having been noticed by Meyer and Sandlund. (*Ph. Ztg.*, 1893, No. 99.) The description in the Br. Pharm. is as follows: "Usually in more or less cylindrical rolls from three to six decimetres long, composed of reddish panicles of pistillate flowers. Panicles much branched, the branches arising from the axils of large sheathing bracts; more or less covered with hairs and glands. Flowers numerous, small, shortly stalked, mostly unisexual, with two roundish, membranous, veined bracts at the base of each. Calyx with reddish veins, hairy externally, and consisting of two alternating whorls each of five segments, the inner whorl being curved inwards over the young fruit and shrivelled. No marked odor; taste bitter and acrid." *Br.*

The N. F. describes the drug as "usually in rolls or flattened bundles from 25 to 50 cm. in length, reddish-brown, or occurring more or less loose and stripped from the larger portions of the panicles. Panicle branches cylindrical, somewhat flattened, longitudinally furrowed or wrinkled, externally light brown to yellowish, tomentose, glandular; internally, cork brownish, bast- and wood-fibers yellow, fibro-vascular bundles in wedges, pith large and yellowish-brown; nodes distinct, each with a scar or branch and subtended by a sheathing bract; internodes mostly from 1 to 2 cm. in length; flowers subtended by two ovate, reddish, pubescent and glandular bracts; pedicel short; calyx turbinate, pubescent below, subtended by four or five rigid, spreading, obovate, purple-veined bractlets which are persistent and elongated in fruit, alternating with and larger than the five usually shriveled, reflexed calyx lobes; petals five, caducous, and usually absent in the drug; carpels two; styles exserted, stigmas broad and hairy with prominent papillæ; fruit an ovoid akene about 2 mm. in diameter, enclosed by the remains of the calyx. The staminate flowers are greenish-yellow, with about twenty fertile stamens. Odor slight; taste bitter. The powdered drug is light brown or reddish-brown and, when examined under the microscope, exhibits numerous simple, non-glandular, straight or curved hairs, up to about 1 mm. in length, with thick, strongly lignified walls, usually enlarged at the base; glandular hairs with one- to three-celled stalks, the glandular head unicellular or consisting of one or two pairs of cells; tracheæ spiral, annular, scalariform, or with bordered pores, up to 0.05 mm. in width; sclerenchymatous fibers long, thick-walled, strongly lignified and with numerous, simple, oblique pores; parenchyma of pith more or less lignified and with large simple pores; fragments of epidermal tissue from the bracts and calyx with elliptical stomata up to 0.03 mm. in length; groups of thin-walled, somewhat branching parenchyma cells with large intercellular spaces; tissue from the inner surface of the pericarp consisting of numerous, elongated, porous, strongly lignified cells; calcium oxalate in rosette aggregates up to 0.04 mm. in diameter; occasionally fragments of tissue containing prisms of calcium oxalate, the latter about 0.014 mm. in length; pollen grains few, nearly spherical, from 0.025 to 0.04 mm. in diameter, with three pores. The larger branches of the panicles exhibit simple, non-glandular hairs up to about 5 mm. in length; tracheæ up to 0.125 mm. in width and rosette aggregates of calcium oxalate up to about 0.075 mm. in diameter. Brayera yields not more than 9 per cent. of ash." *N. F.*

As the medicine, from its high price, is apt to be adulterated, it should be procured in the unpowdered state, in which the botanical characters of the flower will sufficiently test its genuineness. It has a fragrant balsamic odor, and the taste, slightly perceptible at first, becomes in a short time somewhat acrid and disagreeable. Analyzed by Wittstein, it was found to contain, in 100 parts, 1.44 of fatty matter and chlorophyll, 2.02 of wax, 6.25 of bitter acrid resin, 0.77 of tasteless resin, 1.08 of sugar, 7.22 of gum, 24.40 of tannic acid, 40.97 of lignin, 15.71 of ashes, with 0.14 part of loss. It has also been studied by Clemens Willing (*Ch. Cb.*, 1855, 224), and by Pavesi (*Viertelj. f. Prak. Pharm.*, 1858, viii, 505) but we are chiefly indebted to Bedall, of Munich, for determining that the bitter acrid resin of Wittstein is equivalent to the *tæniin* of Pavesi, and for the name of *kosin*. This may be obtained by treating kousso repeatedly with alcohol to which calcium hydroxide has been added; the residue is boiled with water, the liquids are mixed, filtered, and dis-

tilled, and the residue treated with acetic acid, which precipitates the kosin in a white flocculent form, soon becoming denser and resin-like, and, on drying, yellowish, or, at a higher temperature, brown. The product is 3 per cent. In bulk, kosin has an odor like that of Russian leather, a persistent bitter and acrid taste, a yellowish or yellowish-white color, and an indistinct crystalline appearance under the microscope. It is very sparingly soluble in water, but freely so in alcohol, ether, and alkaline solutions. (*A. J. P.*, 1872, 394.) Its formula, according to Flückiger, is $C_{31}H_{38}O_{10}$. It fuses at 142° C. (287.6° F.), and remains after cooling an amorphous yellow mass, but if touched with alcohol it immediately assumes the form of stellate tufts of crystals. This may be repeated at pleasure, kosin not being altered by cautious fusion. (*Pharmacog.*, 2d ed., 258.) Leichsenring (*A. Pharm.*, 1894, 50) has re-examined kousso, and finds an inactive crystalline principle to which he gives the name *protokosine*, and an amorphous substance, *kossotoxine*, which he considers the active principle of the drug; the latter is a yellowish powder, fusing at 80° C. (176° F.), and not obtainable in a crystalline state. It is easily soluble in alcohol, ether, benzene, carbon disulphide, and insoluble in water.

Sodium kosinate has been recommended by Pavesi as a very eligible preparation for obtaining the virtues of kosin; a process is given in *Am. Drug.*, 1884, 96; *A. J. P.*, 1885.

Uses.—Kousso is highly valued in Abyssinia as a vermifuge. Bruce speaks of it in his travels, and gives a figure of the plant. Brayer, a French physician practising in Constantinople, published a treatise on it at Paris in 1823. It was in his honor that Kunth adopted the generic title of the plant. Much attention has been attracted to this valuable medicine, and trials made with it have proved its efficacy in the destruction and expulsion of the *tape-worm*. Its effects when taken internally are not very striking. In the ordinary dose it sometimes produces heat of stomach, nausea, and even vomiting, and shows a tendency to act on the bowels, though this effect is not always produced. It appears to act exclusively as a poison to the worms, and has been found equally effectual in both kinds of *tape-worm*. The medicine is taken in the morning upon an empty stomach, a light meal having been made the preceding evening. A previous evacuation of the bowels is also recommended. The flowers are given in the form of powder, mixed with half a pint of warm water, the mixture being allowed to stand for fifteen minutes, then stirred up, and taken in two or three draughts at short intervals. The medicine may be preceded and followed by lemonade. The medium dose for an adult is half an ounce (15.5 Gm.), which may be diminished one-third for a child of twelve years, one-half for one of six years, and two-thirds for one of three years. Should the medicine not act on the bowels in three or four hours, a brisk cathartic should be administered. One dose is said to be sufficient to destroy the worm. Should the quantity mentioned not prove effectual, it may be increased to an ounce (31 Gm.).

Pure kosin has been considerably used in Germany in doses of thirty grains (2 Gm.), taken in two or four powders; but Buchheim found *pure* kosin less powerful as an anthelmintic than that which was not pure, while Arena (*Ph. Z. R.*, 1879, 655) believes that kosin is not the active principle at all, but that the activity of kousso resides exclusively in the green, slightly bitter resin, which is soluble in alcohol and ether. If this view be correct, it explains the greater efficacy of freshly powdered kousso, for the green resin turns yellow by age and loses its power, and Arena's investigations further indicate that the amorphous kosin of commerce is preferable to the pure principle. It is a yellowish-brown mass, which may be given in doses of from seven to fifteen grains (0.45–1.0 Gm.), repeated every half hour until four doses are taken, to be followed in an hour by a full dose of castor oil. So far as we know, no cases of poisoning by kousso or its active principle are on record, but it has been found by Rochebrune to be capable of causing centric convulsions in the lower animals.

Dose, of kousso, half an ounce (15.5 Gm.); of kosin, seven to fifteen grains (0.45–1.0 Gm.).

DATURÆ FOLIA. Br.

DATURA LEAVES

(dą-tū'ræ fō'lĭ-ą)

"Datura Leaves are the dried leaves of Datura fastuosa, *Linn.*, var. alba, *Nees* and also of Datura Metel, *Linn.*" *Br.*

DATURÆ SEMINA. Br.

DATURA SEEDS

(dą-tū'ræ sĕm'ĭ-ną)

"Datura Seeds are the dried seeds of Datura fastuosa, *Linn.* var. alba, *Nees.*" *Br.*

The genus Datura consists of fifteen species, which are distributed throughout the warmer portions of the whole world, the greatest number being found in Central America. Nearly all of them are used locally in medicine. The plants vary from herbs to shrubs and even trees. The leaves of *Datura Stramonium* are official in the U. S. Pharmacopœia. (See *Stramonium*.) The leaves and seeds of *Datura fastuosa alba* are used in India and the Eastern and West Indian Colonies as an equivalent of Belladonna and Stramonium leaves. A tincture of *Datura seeds* is used in India as an equivalent of Stramonium seeds.

Datura fastuosa is a small shrub, indigenous to tropical India. There is said to be several varieties of this species and it is very generally conceded to be the most toxic of the Indian Daturas. The leaves are ovate and more or less angular, the flowers being white or purplish. *Datura Metel* is also an Indian plant and re-

sembles *D. fastuosa.* It differs in that the leaves are cordate, almost entire, and pubescent. The flowers being white. Pyman and Reynolds (*P. J.*, 1908, lxxxi) have found in the *D. meteloides* a new alkaloid, which they call *meteloidine.*

Of the varieties of *D. fastuosa,* the British Pharmacopœia recognizes that known as *alba.* From it the Thugs prepared the poison Dhât (whence is derived the generic name), which they used to stupefy their victims. The leaves and seeds are recognized by the Br. Pharm. 1914, and the leaves are described as "Brownish or yellowish-green, attaining twenty centimetres in length and thirteen centimetres in breadth; ovate, acuminate, with sinuate-dentate margins and long petioles; often unequal at the base; bearing scattered glandular or simple hairs. Characteristic odor; taste bitter." *Br.*

The trumpet-shaped corolla, together with the stamens, is sometimes found mixed with the leaves. The drug has a slight unpleasant odor, and a bitter taste.

The seeds are "yellowish-brown, somewhat wedge-shaped, flattened, with rounded, thickened, furrowed, wavy margins; from four to five millimetres broad and about one millimetre thick. Hilum large, extending from about the middle to the acute end of the seed. Surface finely pitted and reticulated. Endosperm narrow and translucent, enclosing a curved embryo. No odor; taste slightly bitter." *Br.*

They contain the alkaloid hyoscine, a resin, a fixed oil and traces of hyoscyamine and atropine.

Uses.—While this drug produces effects more or less similar to those of belladonna its precise action has not been clearly determined. It is used in India to a considerable extent as a criminal poison. Banerja (*Indian Med. Gaz.*, 1885, xx, p. 209) has reported 32 cases. The symptoms are not given in sufficient detail to allow of definite statement but seem to differ somewhat from those of either atropine or scopolamine. Gimlette (*B. M. J.*, 1903, i, p. 1137) also records several cases of poisoning and states that the nature of the active principle of the drug has not been determined. In India the *Datura fastuosa* leaves have been used for the same purposes as the stramonium leaves.

Off. Prep.—Tinctura Daturæ Seminum, *Br.*

DECOCTA. U. S.

DECOCTIONS

(dẹ-cŏc'tạ)

Tisanes par décoction, Décoctions, *Fr.*; Abkochungen, *G.*; Decotti, *It.*; Cocimiento, *Sp.*

Decoctions are solutions of vegetable principles, obtained by *boiling* the substances containing these principles in water. Vegetable tissues generally yield their soluble ingredients more readily, and in larger proportion, to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the greatest possible activity in the preparation is desirable. The process should be conducted in a covered vessel, so as to confine the vapor over the surface of the liquid, and thus prevent the access of atmospheric air, which sometimes exerts an injurious agency upon the active principle. The boiling, moreover, should not, as a rule, be long continued, as the ingredients are apt to react on one another, and thus lose, to a greater or less extent, their original character. The substance submitted to decoction should if dry be either powdered or well bruised, if fresh should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful by overcoming the cohesion of the vegetable fiber. Should the physican not happen to prescribe this preliminary comminution, the pharmacist should not omit it.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavorable to its activity, and in a third set is associated with inefficient or nauseous principles, which, though insoluble or but slightly soluble in cold water, are abundantly extracted by that liquid at the boiling temperature, and thus encumber, if they do not positively injure, the preparation. In all these instances, infusion is preferable to decoction. Besides, by the latter process more matter is often dissolved than the water can retain, so that upon cooling a precipitation takes place and the liquid is rendered turbid, and this constitutes the greatest objection to this class of preparations. When the active principle is thus dissolved in excess, the decoction should always be strained while hot, so that the matter which separates on cooling may be mixed again with the fluid by agitation at the time of administering the remedy. In compound decoctions, the ingredients may be advantageously added at different periods of the process, according to the length of boiling requisite for extracting their virtues; and, should one of them owe its activity to a volatile principle, the proper plan is, at the close of the process, to pour upon it the boiling decoction, and allow the liquor to cool in a covered vessel.

As a rule, glass or earthenware vessels should be preferred, as those made of metal are sometimes corroded by the ingredients of the decoction, which thus become contaminated. Vessels of clean cast-iron or common tin, or of block tin, are preferable to those made of copper, brass, or zinc; but iron pots should not be used where astringent vegetable substances are concerned.

Decoctions, from the mutual reaction of their constituents, as well as from the influence of the air, are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, when the weather is warm, for a longer period than forty-eight hours.

The tendency of modern medicine and phar-

macy has been decidedly against the employment of decoctions; their nauseous taste, bulky dose, repulsive appearance, and non-permanent character have been powerful reasons for causing their retirement, while the use of tinctures and fluidextracts has largely increased. In the 1880 revision of the U. S. Pharmacopœia the number of official decoctions was reduced to two, and a general formula was appended for the guidance of the pharmacist. The U. S. P., 1890, reduced the strength of the general formula for decoctions from 10 per cent. to 5 per cent., and this strength was retained in the U. S. P. VIII and IX, as will be seen from the following: "Decoctions must be *freshly made from the drugs,* and, when the strength of decoctions is not otherwise directed, they are to be prepared by the following general formula: * The Drug, coarsely comminuted, *fifty grammes* [or 1 ounce av., 334 grains]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Introduce the drug into a suitable vessel provided with a cover, pour upon it *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of cold water, cover it well, and boil for fifteen minutes. Then allow it to cool to about 40° C. (104° F.), express, strain the expressed liquid, and pass enough cold water through the strainer to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms].

"*Caution.*—The strength of decoctions of energetic or powerful substances should be specially directed by the physician." *U. S.*

The two decoctions of the U. S. P., 1890, *Decoctum Cetrariæ* and *Decoctum Sarsaparillæ Compositum,* were both dismissed in the Eighth Revision and only the general formula for decoctions retained. See *Decoction of Cetraria* Part II, and *Zittman's Decoction,* Part II.

DECOCTUM ACACIÆ CORTICIS. Br.

DECOCTION OF ACACIA BARK

(dẹ-cŏc'tŭm ą-cā'cĭ-æ cŏr'tį-cĭs)

"Acacia Bark, bruised, 60 *grammes;* Distilled Water sufficient to produce 1000 *millilitres.* Boil the Acacia Bark with twelve hundred *millilitres* of Distilled Water, in a suitable vessel, for ten minutes; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used in India as an astringent gargle, lotion, or injection. The *dose* is from four fluidrachms to two fluidounces (15–60 mils).

DECOCTUM AGROPYRI. Br.

DECOCTION OF COUCH GRASS [Decoction of Triticum]

(dẹ-cŏc'tŭm ąg-rō-pī'rī)

"Couch Grass, cut small, 50 *grammes;* Distilled Water sufficient to produce 1000 *millilitres.* Boil the Couch Grass with twelve hundred *millilitres* of Distilled Water, in a suitable vessel, for ten minutes; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used in *cystitis* and *urinary diseases. Dose,* four fluidrachms to two fluidounces (15–60 mils).

DECOCTUM GOSSYPII RADICIS CORTICIS. Br.

DECOCTION OF COTTON ROOT BARK

(dẹ-cŏc'tŭm gọs-sĭp'ī-ī rą'dį-cīs cŏr'tį-cīs)

"Cotton Root Bark, bruised, 200 *grammes;* Distilled Water sufficient to produce 1000 *millilitres.* Boil the Cotton Root Bark with two thousand *millilitres* of the Distilled Water, in a suitable vessel, until the volume is reduced to one thousand *millilitres;* strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used as an emmenagogue and in *uterine hemorrhage. Dose,* from four fluidrachms to two fluidounces (15–60 mils).

DECOCTUM ALOES COMPOSITUM. Br.

COMPOUND DECOCTION OF ALOES

(dẹ-cŏc'tŭm ăl'ọ-ēs cọm-pŏs'į-tŭm)

Tisane (Décocté) d'Aloès composée, *Fr.;* Zusammengesetztes Aloëdecoct, *G.*

"Extract of Aloes, 10 *grammes;* Myrrh, Potassium Carbonate, of each, 5 *grammes;* Extract of Liquorice, 40 *grammes;* Compound Tincture of Cardamoms, 300 *millilitres;* Distilled Water sufficient to produce 1000 *millilitres.* Reduce the Extract of Aloes and the Myrrh to coarse powder, and boil them and the Potassium Carbonate and the Extract of Liquorice with four hundred *millilitres* of Distilled Water in a covered vessel for five minutes; cool; add the Tincture of Cardamoms; set aside for two hours; strain through flannel; pass sufficient Distilled Water through the strainer to produce the required volume." *Br.*

This is essentially the former process of the British Colleges. The effect of the alkaline carbonate is, by combining with the resin of the myrrh and the insoluble portion of the aloes, to render them more soluble in water, while the licorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by preventing spontaneous decomposition. This decoction is said not to filter clear when first made, but, if kept for some time, to deposit insoluble matter, and then to become bright and clear on filtering. (*P. J.,* xiv, 491.) J. F. Brown proposes to prepare a concentrated

decoction which keeps for a long time unchanged. (*C. D.*, 1896, 425.)

Long boiling impairs the purgative property of aloes, and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly qualify its operation and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself; it is also more tonic and cordial, from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the potassium carbonate. It is given as a gentle cathartic, tonic, and emmenagogue, and is especially useful in *dyspepsia, habitual constipation,* and atonic *amenorrhea.* The decoction should not be combined in prescription with acids, acidulous salts, or other bodies incompatible with the alkaline carbonate.

Dose, from one-half to two fluidounces (15–60 mils).

DECOCTUM HÆMATOXYLI. Br.

DECOCTION OF LOGWOOD

(dę-cŏc'tŭm hæ-mą-tŏx'y-lī)

Tisane (Décocté) de Bois de Campêche, *Fr.;* Blauholz-Abkochung, *G.*

"Logwood, in chips, 50 *grammes;* Cinnamon Bark, bruised, 10 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Boil the Logwood with twelve hundred *millilitres* of Distilled Water in a suitable vessel for ten minutes, adding the Cinnamon Bark towards the end of the time; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

We prefer the old U. S. formula, which ordered an ounce of the logwood to be boiled with two pints down to a pint, and doubt much whether the wood is exhausted by a boiling of ten or fifteen minutes. The cinnamon of the Br. formula is in general a very suitable addition, but there might be circumstances under which it would be better omitted, and in this case, as in others, any addition to the simple decoction might be left to the judgment of the prescriber.

This is an excellent astringent in *diarrheas* of relaxation.

Dose, for an adult, two fluidounces (60 mils); for a child about two years old, two or three fluidrachms (7.5–11.25 mils).

DECOCTUM ISPAGHULÆ. Br.

DECOCTION OF ISPAGHULA

(dę-cŏc'tŭm ĭs-pąg'hū-lą)

"Ispaghula, bruised, 15 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Boil the Ispaghula with twelve hundred *millilitres* of Distilled Water, in a suitable vessel, for ten minutes; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used as a demulcent drink in India for *diarrhea.* *Dose,* four fluidrachms to two fluidounces (15–60 mils).

DECOCTUM SAPPAN. Br.

DECOCTION OF SAPPAN

(dę-çŏc'tŭm săp'păn)

"Sappan, in chips, 50 *grammes;* Cinnamon Bark, bruised, 10 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres.* Boil the Sappan with twelve hundred *millilitres* of Distilled Water, in a suitable vessel, for ten minutes, adding the Cinnamon Bark towards the end of the time; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." *Br.*

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used like logwood decoction in India as an astringent in *diarrhea* in *doses* of four fluidrachms to two fluidounces (15–60 mils).

DIACETYLMORPHINA. U. S.

DIACETYLMORPHINE Diacetylmorph.

(dī-ą-cēt'ŷl-mŏr-phī'ną)

"An alkaloid [$C_{21}H_{23}O_5N$ or $C_{17}H_{17}(O.C_2H_3O)_2ON = 369.19$] prepared from morphine by acetylization. Preserve it in well-closed containers, protected from light." *U. S.*

This alkaloid was introduced under the trade-name of *Heroin.* It is made by treating morphine with acetyl chloride, washing the product with a dilute alkaline solution and crystallizing from alcoholic solution. It is officially described as follows: "Diacetylmorphine occurs as a white, crystalline powder without odor. One Gm. of Diacetylmorphine dissolves in about 1700 mils of water, 31 mils of alcohol, 1.4 mils of chloroform, and in 100 mils of ether at 25° C. (77° F.). Its saturated alcoholic solution is alkaline to moistened litmus paper. It melts between 171.5° and 173.5° C. (340.7° and 344.3° F.). Dissolve about 0.01 Gm. of Diacetylmorphine in a few drops of nitric acid; a yellow color is produced, which gradually changes to greenish-blue. Heat about 0.1 Gm. of Diacetylmorphine with 1 mil of alcohol and 1 mil of sulphuric acid; ethyl acetate is produced, recognizable by its odor. No weighable ash remains on incinerating 0.5 Gm. of Diacetylmorphine. Dissolve 0.2 Gm. of Diacetylmorphine in 5 mils of distilled water with the aid of a few drops of hydrochloric acid, and pour this solution slowly into 5 mils of potassium hydroxide T.S., shaking the test tube occasionally; a white precipitate forms, which quickly redissolves, yielding a clear solution (*other alkaloids*). On heating this solution no odor of ammonia is noticeable (*ammonium salts*). A solution of about 0.02 Gm. of Diacetylmorphine in 2 mils of sulphuric acid is colorless (*readily carbonizable organic impurities*). Dissolve about 0.05 Gm. of potassium ferricyanide in 10 mils of distilled water, add

one drop of ferric chloride T.S. and then 1 mil of an alcoholic solution of Diacetylmorphine (1 in 100); no greenish or blue color is produced at once (*morphine*). Dissolve 1 Gm. of Diacetylmorphine in 10 mils of distilled water and 5 mils of diluted hydrochloric acid in a porcelain dish and evaporate the solution on a water bath to a syrupy consistence (about 2 mils). Transfer this residue to a separatory funnel with the aid of 25 mils of distilled water, render it alkaline with sodium hydroxide solution (10 per cent.) and then shake it out with 3 successive portions of 15, 10 and 5 mils of chloroform, passing the chloroform solutions through a small filter previously moistened with chloroform. Carefully evaporate the combined chloroform solutions to dryness on a water bath, dissolve the residue in 10 mils of fiftieth-normal sulphuric acid V.S., add a few drops of methyl red T.S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Not less than 7.5 mils of the latter is required (*foreign alkaloids*)." *U. S.*

A method for the rapid and satisfactory separation of morphine from heroin has been described by J. M. Duran. (*J. A. Ph. A.*, 1916, p. 163.) It is based upon the use of carbon tetrachloride as a shaking out solvent, which has the property of dissolving heroin but not morphine.

For uses, see *Diacetylmorphinæ Hydrochloridum.*

DIACETYLMORPHINÆ HYDROCHLORIDUM. U. S. (Br.)

DIACETYLMORPHINE HYDROCHLORIDE Diacetylmorph. Hydrochl. [Diacetylmorphine Chloride]

(dī-ą-cēt'ȳl-mör-phī'næ hȳ-drǫ-ȼhlō'rį-dŭm)

"The hydrochloride [$C_{21}H_{23}O_5N.HCl + H_2O$ or $C_{17}H_{17}(O.C_2H_3O)_2ON.HCl + H_2O = 423.68$] of the alkaloid diacetylmorphine. Preserve it in well-closed containers, protected from light." *U. S.* "Diamorphine Hydrochloride, $C_{21}H_{23}NO_5$,HCl,H_2O, is the hydrochloride of an alkaloid obtainable by the action of acetic anhydride on morphine." *Br.*

Diamorphinæ Hydrochloridum, *Br.*; Diamorphine Hydrochloride; Heroin Hydrochloride.

The British Pharmacopœia (1914) abbreviated the name of this compound to "Diamorphine Hydrochloride" when it was introduced. It is made by dissolving diacetylmorphine in diluted hydrochloric acid, evaporating and crystallizing the product. (See *Diacetylmorphina.*) It is officially described as follows: "Diacetylmorphine Hydrochloride is a white, crystalline powder without odor. One Gm. of Diacetylmorphine Hydrochloride dissolves in 2 mils of water at 25° C. (77° F.); soluble in alcohol; insoluble in chloroform or ether at 25° C. (77° F.). An aqueous solution of Diacetylmorphine Hydrochloride (1 in 20) is neutral or only faintly acid to litmus. It melts at about 230° C. (446° F.) with decomposition. An aqueous solution of the salt with silver nitrate T.S. yields a white precipitate insoluble in nitric acid. In other respects the salt responds to the tests for identity and purity under *Diacetylmorphina,* omitting the melting point." *U. S.*

"A white, crystalline powder; taste bitter. Melting point from 231° to 232° C. (447.8°–449.6° F.). Soluble in 3 parts of *water* and in 11 parts of *alcohol* (90 per cent.). Yields the *reactions* characteristic of chlorides. 0.1 gramme dissolved in 2 millilitres of *alcohol* (90 per cent.), mixed with 1 millilitre of *sulphuric acid* and warmed, develops an odor of acetic ether. A solution of 0.1 gramme in 1 millilitre of *sulphuric acid* heated on a water bath, cooled and diluted with 6 millilitres of *water,* gives a deep blue color on the addition of an aqueous solution (0.5 in 100) of *potassium ferricyanide* to which 1 drop of *T. Sol. of ferric chloride* has been added. Treated with a few drops of *nitric acid* a yellow color is produced, which changes to greenish-blue on warming, and finally becomes yellow again. 0.02 gramme added to 5 millilitres of an aqueous solution (0.5 in 100) of *potassium ferricyanide,* to which 1 drop of *T. Sol. of ferric chloride* has been added, produces a greenish color and not a deep blue (absence of morphine)." *Br.*

The hydrochloride has the advantage over the alkaloid *diacetylmorphine* because of its much greater solubility in water.

A method for the rapid determination of small quantities of heroin or its salts, especially adapted for revenue officers who are required to give testimony concerning seizures under the Harrison Narcotic Act, was devised by Reginald Miller and is described in *A. J. P.*, 1915, p. 248. It is a colorimetric method, using the formaldehyde sulphuric acid reagent.

Uses.—In its general physiological action *diacetylmorphine* acts much like morphine except that, according to Ott, it is depressant to the spinal cord. It is, however, about twice as powerful in its depressant action upon the respiratory center. For this reason it is greatly inferior to morphine as an analgesic. Its most important use in medicine is as a sedative to the respiratory center; thus it is employed to allay *cough* whether due to *bronchitis* or of nervous origin, to relax the *asthmatic* paroxysm, in *whooping cough, cardiac dyspnea,* and similar conditions. According to Impens (*A. G. P.*, 1899, lxviii, p. 527), although actually more poisonous to the respiratory center it is relatively safer than morphine as disproportionally smaller quantities are needed to exercise therapeutic sedation.

Diacetylmorphine has been employed by physicians in cases in which formation of the drug habit is feared but it is fully as dangerous a drug in this regard as morphine itself, indeed, the diacetylmorphine habit is apparently the more rebellious addiction of the two. Cases of acute poisoning are not very numerous but Trawick (*Kentucky Med. Journ.*, 1911) reports a case, following a dose of one-half a grain, with serious symptoms of the opium type—marked

slowing of the respiration, and contracted pupils. In some cases there is also a semi-delirious condition somewhat resembling that seen in hyoscine poisoning.

Dose, one-sixteenth to one-sixth of a grain (0.004–0.01 Gm.).

Off. Prep.—Elixir Terpini Hydratis et Diacetylmorphinæ, *N. F.*

DIASTASUM. U. S.

DIASTASE

(dī-ăs-tās'ŭm)

"A mixture containing amylolytic enzymes obtained from an infusion of malt. It converts not less than 50 times its weight of potato starch into sugars. Preserve it in well-closed containers, protected from light, heat and moisture." *U. S.*

In germinating grains there is present an enzyme which is capable of converting the starches of the grain into sugar whereby the young plant may be nourished. This diastatic ferment appears to act very much like the ptyalin of the saliva. The substance recognized by the Pharmacopœia under the name of *diastase* is not a pure principle but is a mixture of various inert substances containing the active ferments of malt. It is officially described as follows: "Diastase occurs as a yellowish-white, amorphous powder or in translucent scales; odorless and tasteless. It converts starch into dextrin and maltose. Diastase gradually loses its amylolytic power on keeping; this power is destroyed by heating its solutions above 85° C. (185° F.), or by the addition of much acid and is diminished by the presence of acids or alkalies. Diastase is soluble in water, the solutions being more or less turbid; almost insoluble in alcohol.

"**Assay.**—Mix a quantity of potato starch, purified as directed under *Pancreatinum,* equivalent to 5 Gm. of dry starch, in a beaker with 10 mils of cold distilled water. Add 140 mils of boiling distilled water, and heat the mixture on a water bath with constant stirring for two minutes, or until a translucent, uniform paste is obtained. Cool the paste to 40° C. (104° F.) in a water bath previously adjusted to this temperature. Prepare a fresh solution of 0.1 Gm. of Diastase in 10 mils of distilled water at 40° C. (104° F.) and add it to the paste. Mix them well and maintain the same temperature for exactly thirty minutes, stirring frequently; a thin, nearly clear liquid is produced. Add at once 0.1 mil of this liquid to a previously made mixture of 0.2 mil of tenth-normal iodine V.S. and 60 mils of distilled water; no blue or reddish color is produced." *U. S.*

Diastase being one of the newer enzymes produced commercially is frequently found upon the market in an impure or adulterated condition, samples having been observed containing as much as 60 per cent. of starch. Much of the commercial diastase is variable in strength and frequently it is almost inert. *Takadiastase* is the name of a proprietary form of diastase which is not produced from malt but is produced by the growth of certain species of *aspergillus* upon rice hulls or bran. In Japan takadiastase is used in the brewing industry as malt is used in other countries.

Uses.—Diastase was introduced into medicine with the idea that by virtue of its power of digesting starches it would be useful in *fermentative dyspepsia.* In those rare cases where there is an organic deficiency of saliva, or in the more frequent condition where the patient is too lazy to masticate his food, it may be of service but as its action upon the starch is similar to that of the ptyalin of saliva its range of usefulness as a digestant is certainly not very wide.

The *dose* is five to fifteen grains (0.32–1.0 Gm.).

DIGITALIS. U. S. (Br.)

DIGITALIS Digit. [Foxglove, Digitalis Folium P. I.]

(dĭj-ĭ-tā'lĭs)

"The carefully dried leaves of *Digitalis purpurea* Linné (Fam. *Scrophulariaceæ*), without the presence or admixture of more than 2 per cent. of stems, flowers or other foreign matter. If made into the official tincture and assayed biologically the minimum lethal dose should not be greater than 0.006 mil of tincture, or the equivalent in tincture of 0.0000005 Gm. of ouabain, for each gramme of body weight of frog. Digitalis should be preserved in tightly-closed containers protected from light." *U. S.* "Digitalis Leaves are the dried leaves of Digitalis purpurea, *Linn.,* collected from plants commencing to flower, thoroughly dried at a low temperature, and kept dry in well-filled air-tight containers. When powdered no portion should be rejected." *Br.*

Digitalis Folia, *Br.,* Digitalis Leaf; Digitalis Leaves, Foxglove Leaves; Fairy Cap, Fingers, Thimbles, or Bells, Lady's Glove, Purple Foxglove, Flop-dock, Throatwort, Cottagers; Digitale, *Fr. Cod.;* Feuilles de Digitale Pourprée (de grande Digitale), Digitale Pourprée, Doigtier, *Fr.;* Folia Digitalis, *P. G.;* Purpurrother Fingerhut, Fingerhutkraut, Fingerhut blätter, *G.;* Digitale, *It.;* Digital (Hoja de), Dedalera, *Sp.*

The foxglove is a beautiful plant, with a biennial or perennial fibrous root, which in the first year sends forth large tufted leaves, and in the following summer a single erect, downy, and leafy stem, rising from two to five feet, and terminating in an elegant spike of purple flowers. The lower leaves are ovate, pointed, about eight inches in length and three in breadth, and stand upon short, winged foot-stalks; the upper are alternate, sparse, and lanceolate; both are obtusely serrate, and have wrinkled velvety surfaces, of which the upper is a fine deep green, the under paler and more downy. The flowers are numerous, and attached to the upper part of the stem by short peduncles, in such a manner as generally to hang down upon one side. At the base of each peduncle is a floral leaf, which is sessile, ovate, and pointed. The calyx is divided into five segments, of which the uppermost is narrower than the others. The corolla is monopetalous, bell-form, swelling on

the lower side, irregularly divided at the margin into short obtuse lobes, and in shape and size not unlike the end of the finger of a glove, a circumstance which has suggested most of the names by which the plant is designated in different languages. Its mouth is guarded by long soft hairs. Externally, it is in general of a bright purple; internally, it is sprinkled with black spots upon a white ground. There are numerous garden varieties, one having white flowers. The filaments are white, curved, and surmounted by large yellow anthers. The style is simple, and supports a bifid stigma. The seeds are numerous, very small, grayish-brown, and contained in a pyramidal two-celled capsule. All of the species of the genus *Digitalis* seem to have similar effects upon the system. Miller and Baker (*J. A. Ph. A.*, March, 1914) examined 23 different species or varieties of *Digitalis* and found that one or two, indeed, surpassed the *D. purpurea* in power.

Foxglove grows wild in the temperate parts of Europe, where it flowers in the middle of summer. In this country it is cultivated both for ornament and for medicinal use. (For methods of cultivation in the United States, see Newcomb, *A. J. P.*, 1911, p. 529; Borneman, *A. J. P.*, 1912, p. 547; Miller, *A. J. P.*, 1913, p. 297.) The leaves are the part generally employed. The U. S. Pharmacopœia IX departed from the ancient requirement, and in our opinion properly so, that digitalis should be collected only in the second year. Modern investigators, such as Sharp (*P. J.*, lxxxix, 131), Miller and Baker (*J. A. Ph. A.*, 1913, ii, 198), and Carr (*A. J. P.*, 1913, lxxxv, 297) are unanimous that the first year's leaves are fully as powerful as those collected just before flowering. Hale (*Proc. A. Ph. A.*, 1910, 294), as well as Miller and Baker, finds that there is no difference between the wild and cultivated plants; indeed, the latter say even if grown in hot houses. Likewise the formerly accepted view that digitalis leaves deteriorate rapidly has been shown to be erroneous. Hatcher and Eggleston (*A. J. P.*, 1913, 203) have found that the loss of potency in properly dried leaves was not more than 2 per cent. a year, and Haskell and Miller (*J. A. Ph. A.*, 1914, iii, 306) were unable to detect any change after 12 months. In drying the leaves should not be exposed to a temperature of more than 120° C. (248° F.) for the last named investigators found that, although this temperature had no effect on the quality of the drug, 140° C. (284° F.) was distinctly injurious.

The seeds contain more of the active principle than the leaves, are less likely to suffer in drying, and keep better, but are nevertheless little used. So far as the relative strength of these two parts can be determined from that of their alcoholic extracts, it would appear, from the experiments of Hirtz, that the seeds are ten times stronger than the leaves. (See *A. J. P.*, xxxiii.)

Properties.—Fresh digitalis leaves are without odor but acquire a faint odor when dried. The color of the dried leaf is a dull pale green, modified by the whitish down upon the under surface; that of the powder is a fine deep green. They are officially described as: "Leaves, when entire, attaining a length of 30 cm. and a breadth of 15 cm., ovate to oval, abruptly contracted into winged petioles, the latter from 5 to 10 cm. in length or, in the smaller leaves, nearly absent; margin crenate, irregular (the commercial article usually more or less crumpled and broken), thin, dull, pale green or gray and densely pubescent on the lower surfaces; upper surfaces wrinkled, sparsely hairy; the venation conspicuously reticulated; the midribs and principal veins broad and flat, often purplish, the lower veins continued into the wings of the petioles; odor slight, characteristic; taste strongly bitter. The powder is dark green; with numerous fragments of non-glandular hairs consisting of from 2- to 8-cells (usually 2- to 5-cells), varying in length from 0.145 to 0.435 mm., some of the cells being frequently collapsed; glandular hairs few, small, with a 1- or 2-celled stalk and a 1- or 2-celled glandular head; numerous irregular fragments of lamina showing stomata and occasional waterpores and elongated fragments of veins and petioles showing fibro-vascular tissues. Digitalis yields not more than 15 per cent. of ash." *U. S.*

The British Pharmacopœia description is as follows: "Hairs of two kinds, either simple, mostly 3–5 celled and bluntly pointed, or glandular and consisting of a short pedicel bearing a unicellular or bicellular gland. In transverse section, no sclerenchymatous cells or fibres, and no crystals of calcium oxalate. In the powdered Leaves, groups of epidermal cells with more or less sinuous walls, numerous fragments of multicellular hairs with thin, granular walls; but no sclerenchymatous cells or fibres, or crystals of calcium oxalate. No marked odor; taste very bitter." *Br.*

For a comprehensive description of the morphology and anatomy of the leaves of *Digitalis purpurea* and the adulterants of this drug, see Bohny's article in *Bot. Centralbl.*, 1906, p. 267. Collin reviews the pharmacognosy of Digitalis (*J. P. C.*, 1905, p. 56), showing the characteristics of the powder and the detection of the principal leaf adulterants, such as *Inula Conyza, Verbascum phlomoides, Artanthe elongata,* and *Salvia Sclarea.* Kraemer (*A. J. P.*, 1912, p. 35) discusses the morphology of digitalis leaves and shows the variation and the forms of hairs in different commercial specimens.

Digitalis yields its virtues both to water and to alcohol. It contains, besides active principles, a volatile oil, a fatty matter, a red coloring substance analogous to extractive, chlorophyll, albumen, starch, sugar, gum, lignin, and salts of potassium and lime, among which, according to Rein and Haase, is acid potassium oxalate. Morin, of Geneva, discovered in the leaves two acids: one fixed, called *digitalic acid,* the other volatile and resembling valerianic acid, which he proposed to name *antirrhinic acid* (*P. J.*,

vii, 294). England (*A. J. P.*, 1892, 361) found about 5 per cent. of fixed oil in digitalis leaves. Morries obtained a narcotic empyreumatic oil by the destructive distillation of the leaves. The yield of ash from digitalis leaves is usually put down at from 7 to 10 per cent., and this is in accord with the result reached by F. H. Alcot with British leaves. (*P. J.*, Jan., 1903.) On the other hand, M. Greshoff (*P. J.*, Dec., 1902) has obtained in various samples of German digitalis, after the leaves have been freed from sand and the leaf-stalks removed, a yield of from 16.4 to 25 per cent. of ash.

Under the name of *digitalin* there have long been in commerce two distinct substances obtained from digitalis, both of them crude mixtures of the glucosidal principles. The *French* digitalin was that originally prepared by Homolle. It is a whitish powder, of a neutral reaction, soluble in 2000 parts of cold and in 1000 parts of hot water. It is this digitalin which was formerly recognized by the U. S. and Br. Pharmacopœias. See *U. S. Dispensatory*, 19th edition, p. 424. The so-called *German* digitalin is distinguished from the French by being, in great part or entirely, freely soluble in water.

In 1871, Nativelle received from the French Academy the prize of Orfila for the discovery of the active principle of digitalis. The method of preparation, as finally improved and modified by himself, and published in the *J. P. C.*, xx, 1874, p. 81, and also a process which has the advantage of being far shorter and more readily carried out, devised by Tanret (*Ibid.*, Oct., 1875), may be found on p. 1143, 14th ed., *U. S. D.*

According to the researches of Schmiedeberg (*P. J.*, (3) v, 741), confirmed by Kiliani (*P. J.*, (3) xxii, 1061, and (4) i, 29), the seeds and leaves of *Digitalis purpurea* contain a preponderating amount of a glucoside, *digitonin*. They contain in addition three other substances which possess the power of acting on the heart, namely, crystallizable *digitoxin* and two amorphous glucosides, *digitalin* and *digitalein*.

Digitonin forms fully one-half of the mixed glucosides from the digitalis seed and the principal portion of German "digitalin," from which it may be prepared by extraction with and crystallization from 85 per cent. alcohol. Digitonin softens at 225° C. (437° F.), and melts completely at 235° C. (455° F.). The crystals dissolve sparingly in cold water, more readily in hot, to an opalescent solution which froths on agitation. It cannot be crystallized from water. The aqueous solution is lævorotatory ($[a]_D$ = — 49 at 25° C. [77° F.]), and is precipitated by tannin, ammoniacal lead acetate, and baryta water. Digitonin is only slightly soluble in absolute alcohol, and still less so in ether, chloroform, or petroleum benzin. It forms a crystalline compound with amyl alcohol. According to Kiliani, digitonin has the formula $C_{27}H_{46}O_{14} + 5H_2O$, and when boiled with strong alcohol and hydrochloric acid splits up into *dextrose*, *galactose*, and *digitogenin*, the last body separating in warty masses on cooling. Digitonin does not possess the characteristic physiological properties of digitalis; its action is similar to that of the saponins.

Digitoxin is characterized by its free solubility in alcohol and chloroform, slight solubility in ether, and insolubility in petroleum benzin. It crystallizes from alcohol in pearly scales or needles which melt at 240° C. (464° F.). It is quite insoluble in water, to which it does not impart even a bitter taste. Warmed with strong hydrochloric acid, it gives a yellow or greenish coloration, which is one of the reactions ascribed to the "digitaline crystallisée" of the French Codex. Schmiedeberg states that it is not a glucoside, but Kiliani asserts that upon heating its alcoholic solution with hydrochloric acid it splits up into *digitoxigenin* and a sugar, *digitoxose*. The reaction for this is now considered to be:

$$C_{34}H_{54}O_{11} + H_2O = C_{22}H_{32}O_4 + C_6H_{12}O_4$$

Digitoxin is found mainly in the leaves (Kiliani stating that it is not found in the seeds at all), but Keller (*P. J.*, July 24, 1897) finds it also in the seeds in smaller amount. It is the most poisonous of the constituents of digitalis.

Digitalin (*Digitalinum verum* of Kiliani) forms a white amorphous powder or soft white grains which remain unchanged when heated to 200° C. (392° F.), at 210° C. (410° F.) begin to aggregate, and towards 217° C. (422.6° F.) melt, becoming yellow. When treated with water the particles of digitalin swell up and dissolve slightly, giving a solution which foams strongly on agitation. It is dissolved sparingly (1 to 100) by cold proof spirit, but in considerable amount by hot rectified spirit or absolute alcohol. When a minimum of alcohol is used, the solution on cooling becomes almost solid from the separation of a thick magma of granules, which are, however, destitute of crystalline structure. This peculiar behavior affords a valuable means of testing its purity, as only a small percentage of the other glucosides with the digitalin prevents the formation of the granules. The minutest admixture of amorphous glucosides also rapidly causes an intense yellow coloration. Digitalin is very sparingly soluble in ether or chloroform. When digitalin is heated with diluted hydrochloric acid, an insoluble resinous substance almost immediately separates out; Schmiedeberg termed this *digitaliresin*. By operating in alcoholic solution, Kiliani avoids the separation of resin, and finds that digitalin splits up as a glucoside into *digitaligenin*, *glucose*, and *digitalose*, thus:

$$C_{29}H_{46}O_{12} + H_2O = C_{16}H_{22}O_2 + C_6H_{12}O_6 + C_7H_{14}O_5$$

Kiliani found that commercial *digitalinum purum* contained but 5.5 per cent. of true digitalin.

Digitalein is considered to be a distinct glucoside by Schmiedeberg, but Kiliani, who

worked over it later, regards its independent existence as questionable.

GITALIN has been described by Kraft (*S. W. P.*, 1911, xlix), who believes that digitalein is an impure form of gitalin. The latter is an amorphous white powder soluble in 600 parts of water. It can be obtained also as a crystalline hydrate.

DIGITIN of Schmiedeberg is also considered by Kiliani to be simply digitonin.

The above résumé of our present knowledge clearly shows that the chemistry of digitalis cannot be considered as settled; but it also clearly shows that no "digitalin" completely represents digitalis. Moreover, the digitalin of commerce varies greatly. (See *A. Pharm.*, 1895, 299; also 1895, 698.)

Assay.—Three animals have been suggested as reagents for the biological standardization of digitalis, the frog, the guinea-pig, and the cat. The most commonly used is the frog. Although a number of writers had employed physiological tests to determine the relative potency of different digitalis bodies, the first to use the biological assay in a systematic manner was Houghton, who used what is now known as the "twelve hour frog method."

The U. S. P. recommends the frog method for the biological assay of digitalis and describes it as follows: "For the members of the digitalis series the so-called "one hour frog" method is recommended. This method consists essentially in ascertaining the dose of a drug or preparation which will bring the heart of a standard sized frog to systolic standstill in one hour's time. The method is carried out as described below; all measurements being performed with the same degree of accuracy used in ordinary quantitative chemical estimations.

"*Frogs.*—The frogs to be employed in an assay should be in a healthy condition and of the same species. Those most commonly obtainable in this country are the common grass frogs (*Rana viridis* or *Rana pipiens*). While the dose for a frog is estimated according to its weight, it is best to use frogs of a fairly uniform size, the most convenient weight for such work being between 15 and 25 Gm.

"*Storage.*—Before use the frogs should be stored in tanks kept in a cool room, preferably where the temperature does not rise above 15° C. (59° F.). The bottom of the tanks should be covered with running water or, if running water is not convenient, standing water may be used if it is changed from two to four times daily. An hour before the frogs are to be used for an assay a sufficient number should be taken to the operating room, each one carefully weighed to within 0.1 Gm. and placed in an individual wire cage or container, these are then placed in a tank containing water to the depth to about 1 cm. (½ inch), which is kept during the process of assay at a uniform temperature of 20° C. (68° F.). The maintaining of a uniform temperature at which all assays of the members of this group should be carried out is important, as the susceptibility of frogs differs very considerably at different temperatures.

"*Dosage.*—After the frogs have been weighed as described, the doses to be given are calculated according to their weights and are measured into small conical glasses by means of a finely graduated pipette. The doses of the preparation which are to be injected should be as uniform in quantity as possible and should not exceed 0.015 mil for each gramme of body weight of frog. The members of the digitalis series may be assayed in either fluidextract or tincture strength, being diluted with water as may be necessary to get the volume dose. In case the alcohol content in any preparation after dilution is higher than 20 per cent., the preparation may be subject to careful evaporation and subsequent dilution with an aqueous solution containing 0.7 per cent. of sodium chloride until the original volume is restored and the alcohol content is not above the per cent. named. It is always best to have the alcohol content of different preparations uniform. In case there is a precipitate the preparation to be assayed should be shaken each time a dose is measured out. When the doses are ready, they may be injected into the anterior lymph sac of the animal. This is done by means of a glass pipette which is drawn out to a fine point. The frog is held on its back in one hand and the pipette with the contained drug in the other, the mouth of the frog is operated with the point of the pipette and, carefully avoiding the tongue, the floor of the mouth is punctured and the point of the pipette is then seen to enter the anterior lymph sac of the frog. The contents of the pipette are now forced into the sac either by gravity or by gently blowing, if necessary. In the latter case, care should be taken not to introduce air into the sac. Care should also be taken not to puncture the skin. The animal is then replaced in its cage in the tank, the temperature of which is maintained as stated at 20° C. (68° F.). At the end of one hour from the time of injection each frog is pithed, both brain and cord, the heart is exposed and its condition examined. For the correct end reaction the ventricle should be in systolic standstill while the auricles should be widely dilated. Following mechanical stimulation feeble contractions may be allowed in the auricles and localized contractions in the ventricle, but no general contraction is allowable. If when the heart of an animal is being exposed for examination, remains of the injected drug are found in the lymph sac unabsorbed, such an animal should be discarded and not considered in the results obtained. It happens sometimes that one frog out of a large series may prove a decided exception to the others in the way of increased or decreased susceptibility to the drug. Such an animal should also be discarded. After the primary or trial assay has been carried out and the approximate strength of the preparation ascertained, a second series of frogs is injected in like manner, using doses the limits of which are considerably narrower than the first series. A third or even fourth series of injections may be necessary to

confirm the earlier results. The dose thus found is then compared with the dose of a standard which is similarly ascertained upon another series of frogs of the same lot. From such a comparison the strength of the unknown preparation can be suitably adjusted. The use of a standard is made necessary by the fact that frogs differ in their susceptibility to the members of the digitalis series at different seasons of the year. The condition of susceptibility is ascertained and allowed for by the use of a solution of ouabain (see Part III) as a standard which in appropriate doses is injected into a series of frogs and their resistance thus determined. The necessary strength of an unknown preparation may be calculated from the dose actually found by the ratio of the standard dose of ouabain to the dose of ouabain found necessary to kill. Thus:

"Standard dose of ouabain : Found dose of ouabain :: Standard dose of drug being assayed : Necessary dose of unknown.

"The standard dose of ouabain is 0.0000005 Gm. per gramme of body weight of frog. The standard dose of Tincture of Digitalis to correspond is 0.006 mil per gramme of body weight of frog. If, therefore, in a certain series of frogs the resistance to ouabain is found to be increased so that a dose of 0.00000075 Gm. is necessary to stop the heart in systole in one hour, the dose of Tincture of Digitalis would also have to be increased to 0.009 mil, and the actual dose found calculated against this, instead of against the standard dose of 0.006 mil. For example, in frogs showing the increased resistance as indicated above, if the Tincture being examined assays 0.018 mil per gramme of body weight it is one-half strength.

"*Standards.*—The standards adopted are as follows:

	Gramme or mil for each gramme of body weight of frog
Standard dose of ouabain.....	0.0000005
Digitalis	
Leaves (in the form of tincture)	0.0006
Fluidextract	0.0006
Tincture	0.006." *U.S.*

Houghton prefers that the observation be made at the end of 14 or 15 hours, instead of one hour. Focke (*A. Pharm.*, 1907) modifies the frog's heart method by using a constant dose, the time of arrest being the variant which furnishes the index to relative potency. Because of the variation in the susceptibility of frogs at different times of the year, it has been suggested that the frogs be standardized by testing the susceptibility representatives of each batch of frogs being tested with strophanthin.

The "guinea-pig method" consists in simply finding the minimum lethal dose for a guinea-pig. To a series of previously weighed guinea-pigs is administered hypodermically ascending doses of a tincture of the sample to be tested. The end-point of the test is the smallest dose which will kill the guinea-pig within twenty-four hours. The method is essentially similar to that employed for aconite. (See *Aconitum.*)

A much more elaborate method has been suggested by Hatcher. He has found that the lethal dose of crystalline strophanthin (ouabain) for the cat is very constant, being almost exactly 0.1 milligramme per kilogramme of body weight when administered intravenously. The method of assay is to give a quantity of the sample to be tested, of about two-thirds of the expected fatal dose for the cat, and then run in slowly a solution of strophanthin until death is caused. The difference between the ordinary fatal dose of the glucoside and the quantity used in the test represents the amount of strophanthin to which the digitalis being tested is equivalent; that is, the larger amount of strophanthin which has been used, the weaker is the preparation. It is at present hardly possible to decide which of these methods for the biological testing of digitalis is the most reliable. The cat-method of Hatcher is practically out of the question for any commercial purpose, not merely because of the technical difficulties, but chiefly because of the limited supply of cats. Each of the other methods has its advocates.

Among the most important objections to the frog methods of standardizing are the facts that not only is there great difference in susceptibility between different species of frogs, but also in the same species at different seasons of the year. Focke, for instance, has found that the frog in the spring was twice as resistent to digitalis as in the fall. (*A. Pharm.*, 1907.) This variation is due in part to the difference in temperature at various seasons of the year but also in part to the nutritional condition of the batrachian. For this reason the U. S. P. recommends that the frogs be standardized by testing their resistance against crystalline strophanthin. It is doubtful, however, whether this standardization of a frog is of any great usefulness for the reason that the relative toxicity of various members of the digitalis series to the cold blooded animal bears little correspondence to their relative power in man. The question of whether or not the guinea-pigs show seasonal variation in susceptibility to digitalis is still open for difference of opinion. See Haskell (*A. J. P.*, 1914, lxxvi, p. 7).

After all none of these methods of biological standardization of digitalis and its congeners can be regarded as an accurate method for the assay in the same sense that chemical standardization is; their chief utility is in preventing inert preparations of digitalis from being placed upon the market. An interesting fact was brought out in Bulletin No. 48 of the United States Hygienic Laboratory by Edmunds and Hale. It is that if two samples be tested by different methods, one may be found to be more toxic in the frog, and the other more toxic to the guinea-pig.

For a discussion of the various details of the methods for the assay of digitalis, see Haskell (*A. J. P.*, 1914, lxxxvi, p. 7); Focke (*Z. E. P. T.*, 1909, vii, p. 1); Edmunds and Hale (*U. S. Hygienic Laboratory Bulletin* No. 48, 1909);

Hatcher (*J. A. M. A.*, 1910, lv, p. 746); Houghton and Hamilton (*A. J. P.*, 1909, li); Hamilton and Rowe (*J. A. Ph. A.*, 1915, iv, p. 108); Vanderkleed and Pittenger (*J. A. Ph. A.*, 1914, iii, 815).

No satisfactory chemical assay process has yet been devised for digitalis and hence the U. S. P. contains no process. The amount of digitoxin present in digitalis has been proposed by several investigators as a means of standardizing it, but it is by no means clear that this is a reliable criterion. Several attempts have been made to estimate the practical usefulness of the assay for digitoxin by comparing the results with the physiological tests of digitalis. While some experimenters have found a fairly close agreement between them, the great majority of those who have studied the question incline to the opinion that the two methods of assay do not run at all parallel. There are three possible reasons for this variation and each one of them seems to be operative. These are, first, inaccuracies in the chemical method for assaying digitalis; second, the unavoidable inaccuracy of the biological assay; third, the fact that the relative quantity of digitoxin to the other constituents of digitalis may vary from one sample to another.

While digitoxin is the most important constituent of digitalis it is by no means the only important one. The experiments of Lutzkaga (*A. J. P. T.*, 1908, xviii) and those of Barger and Shaw demonstrate that between 60 and 70 per cent. of the activity of digitalis leaf is due to its digitoxin, and that the proportion of digitoxin cannot be relied upon as a criterion of the quality of the drug. (See *Ber. d. Chem. Ges.*, 1897; *Pharm. Rev.*, 1901, 514; *D. C.*, 1902, 223; *P. J.*, 1902, 663; *Chem. News*, 1903, 123; *A. Pharm.*, 1903, 358.) J. Gordon Sharp proposed a test for digitalis based upon the fact that the leaves contain an enzyme, which acts on amygdalin producing an odor like that of bitter almond with hydrocyanic acid. (*P. J.*, 1902, 236.)

Uses.—Although digitalis appears to have been used by the inhabitants of Britain as far back as the tenth century of the Christian Era, it was introduced into regular medical practice by William Withering in 1775, who obtained his knowledge of the value of foxglove in dropsy from an old woman of Shropshire.

The opinion of the medical profession as to the mode of action of digitalis and the class of cases in which it is useful has undergone many changes. Recent studies have led to another one of these revisions of the accepted belief concerning the effects of this drug upon the system, especially upon the circulation.

When given in small dose, that is, in quantities barely sufficient to cause any visible change, the only marked effect of digitalis upon the circulation is a slowing of the pulse, which is due to a stimulation of the inhibitory mechanism of the heart. After somewhat larger quantities the heart-beat becomes extremely slow, the size of the wave very large, and the vigor of the contraction of the heart perhaps a little increased, but the blood pressure is not materially affected because of the great reduction in pulse rate.

Despite the fact that there is no increase in arterial pressure it is probable that even at this stage of the action of the drug there is more or less stimulant effect upon the vasomotor mechanism, the pressor effect of the vascular constriction being overcome by the great reduction in the pulse rate. When toxic doses are administered the blood pressure is distinctly, and sometimes greatly, elevated. This is brought about partially by an increased vigor of the heart's contraction, but probably in greatest part by constriction of the blood vessels. Often at this stage there appear various forms of cardiac irregularities, the most common of which is that which is known as an "extra-systole"; the irritability of the heart muscle is so greatly increased that before the completion of the diastolic period a new contraction interrupts the relaxation. Sometimes these extra-systoles occur regularly with every alternate beat of the pulse, producing the so-called *pulsus bigeminus* (sometimes incorrectly called a dicrotic pulse). Later on in the poisoning the cardiac contractions become extremely rapid, more or less irregular, and the diastole never complete. Eventually in the frog the ventricle passes into a condition of permanent contraction, or, as it is more frequently called, systolic spasm. In the warm-blooded animal, however, the heart relaxes immediately before death and passes into a state of fibrillation.

Under certain conditions digitalis produces a marked increase in the flow of urine. Apparently in normal health it has little or no diuretic action. Its effect upon the kidney appears to be the result of the reaction of the renal artery. Joseph (*A. E. P. P.*, 1913, lxxiii, p. 81) has shown that the contraction of the renal artery by digitalis is less than that in the rest of the body and that after small doses there may even be an actual dilatation of the blood vessels of the kidney. This, of course, means that a larger proportion of the blood is driven to these organs and consequently there will be a freer secretion.

Digitalis is used in practical medicine for three purposes, as a stimulant in acute circulatory failure, as a diuretic, and as a cardiac tonic in chronic heart disease.

As a circulatory stimulant digitalis is a remedy of only secondary importance. In the first place, in the acuter forms of *circulatory failure*, such as *surgical shock*, when given by the mouth it is so slow in its action that the condition will have terminated one way or the other before it begins to influence the circulation. When given hypodermically it is intensely irritant and even by this channel its effects are too slow to be of much service, and although certain proprietary preparations are upon the market which are suitable for intravenous injection, there is no

reason to believe them superior for this purpose to strophanthin. In *infectious fevers* the weakness of the heart manifests itself sufficiently gradually that there is usually time enough for the action of the drug, but unfortunately clinical experience has shown that in this condition its power is much diminished.

As a diuretic digitalis is of service whenever there is *dropsical accumulation.* How far the beneficial effects are the result of improvement in the circulation and how far from a direct action upon the kidney is somewhat doubtful.

The most important use of this drug is in the treatment of various forms of *chronic heart disease,* including those due to *valvular lesions,* various types of *myocarditis,* and the *cardiac neuroses.* Its beneficial influence in these states is probably the result of several factors: the stimulation of inhibition gives the heart more time to rest, the increased force of the contraction improves the nutrition of the heart muscle, the diuresis, which occurs if there be edema, lessens the burden upon the diseased heart. Although this drug is, in a large number of cardiac conditions, the most important remedy we possess it must not be regarded as a panacea for all forms of chronic heart disease. A discussion of the various forms of cardiac weakness in which this drug is indicated or contra-indicated can scarcely be undertaken in this place, and the interested reader is referred to H. C. Wood, Jr.'s *Text-book of Pharmacology* for further information.

The active principles of digitalis are absorbable through the skin and the external application of digitalis poultices was formerly used to a considerable extent in the treatment of dropsies.

When given by the mouth digitalis acts very slowly, its effects often not being manifest for twenty-four or forty-eight hours after its administration. Its action, however, when once it begins is equally persistent. At times when the drug is being used continuously no evidence of its action may be manifest for several days and then suddenly symptoms of toxic effects come on. This is what is meant by the term "cumulative action."

Preparations of digitalis vary so much in their potency, and the conditions in which it is used so frequently demand the full actions of the drug, that the therapeutist should be guided in his dosage only by the degree of effect. The two most important symptoms indicating that the patient is taking as much as he can stand are great reduction in the rate of the pulse—say below sixty per minute—or the occurrence of nausea.

The symptoms of digitalis poisoning are nausea and vomiting, with muscular weakness, the pulse is at first very slow, may fall to thirty or forty a minute, and in severe cases later becomes very rapid and irregular. In some instances the pulse may be slow as long as the patient remains in a recumbent posture but becomes rapid if he assumes an upright position. Outside of the evacuation of the stomach and keeping the patient lying down there is no treatment of the poisoning which is known to be efficacious, although Zugsmith has reported favorable results from the external application of heat.

Preparations.—Because of the variability of the official preparation of digitalis and of their liability to produce gastric disturbances, a large number of proprietary preparations of the drug have been placed upon the market. It may be pointed out in connection with these substances that Hatcher and Eggleston (*J. P. Ex. T.,* 1912, iv, 113) has shown that the nauseating action of digitalis is due chiefly to the effects of its active principles upon the vomiting center in the medulla, and that any preparation, therefore, which does not nauseate is therapeutically useless. In the second place, it is not probable that any single principle of the drug has exactly the same influence upon the circulation as the whole leaf. The following are some of the more important preparations of digitalis.

Digitalinum Gallicum, French digitaline, also known as *digitaline chloroformique* and as *Homolle's digitaline.* This is official in the French and Belgian Pharmacopœias, is almost insoluble in water, and is said to consist largely of a glucoside allied to, or identical with, digitoxin. (See *P. J.,* 1898, 506.) The dose of the commercial article may be put down as about one two-hundred and sixtieth of a grain (0.00025 Gm.), to be repeated several times per day, the maximum daily dose being one-fortieth of a grain (0.0016 Gm.). The granules of Homolle, which were formerly used in Europe, each contained a milligramme, or about one-sixtieth of a grain, probably equivalent, on the average, to a grain and a half of digitalis of medium strength. One of these globules is usually given as a commencing dose. Forty of them taken with a view to suicide, though followed by copious vomiting, produced the most alarming prostration, with a weak pulse, from 46 to 48 in a minute, intermittent, and at times scarcely perceptible. The patient, however, ultimately recovered. (*Ann. Thér.,* 1858, 103.)

Digitoxin has been used to a certain extent clinically. According to the experiments of Fraenkel, however, it is more liable to give rise to cumulative effects than is the crude drug. It is almost insoluble in water and is locally irritant. *Dose,* one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.).

Digitalinum Germanicum, also known as *Merck's digitalin* or *German digitalin.* This is practically a concentrated extract of the digitalis seeds. It probably contains true digitalin, and digitalein, as well as digitonin. The dose is from one-tenth to one-half a grain (0.005–0.03 Gm.).

Digalen is claimed to be a *soluble digitoxin,* but such a statement is manifestly impossible. The claim of its discoverer Cloetta that it is isomeric with digitoxin but has twice the molecular weight of digitoxin, would seem to disprove

its identity. According to Kiliani (*M. M. W.*, 1907), it is identical with digitalein.

Digipuratum is a yellowish powder which is asserted to contain all the active glucosides of digitalis leaves in the form of tannates without various objectionable constituents. It is physiologically standardized by tests upon frogs. The dose is the same as that of the leaves.

Of the various pure principles of digitalis the doses are as follows: *Digitalein,* one-sixtieth to one-thirtieth of a grain (0.0011–0.002 Gm.); *digitoxin,* one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.); *Kiliani's digitalinum verum* has not been used enough clinically to determine the proper dose.

There are two substances known as *crystallized digitaline,* one of which, the *digitaline crystallisée* of the French Codex also known as *Nativelle's digitalin,* is probably identical with digitoxin. Merck's *crystallized digitaline* appears to be largely composed of digitonin and does not therefore represent the physiological properties of digitalis.

Digifolin is asserted to contain the cardiac principles without the saponins of digitalis. It is marketed in the form of tablets and of ampoulæ, each of which represents one-sixth of a grain (0.01 Gm.) of digitalis leaves. *Digipan* is a preparation of the same nature which is issued both in tablets and in solution, the dose of the tablets being one or two and of the solution fifteen drops (0.9 mil). *Adigan* is also a saponin free preparation but does not seem to have been proven clinically. *Digitol* is standardized tincture made from leaves freed of their fatty matters by treating with benzin. The *dose* is the same as of the official tincture.

Dose, of digitalis leaves, one to two grains (0.065–0.13 Gm.).

ELATERINUM. U. S.

ELATERIN Elaterin.

(ĕl-ă-tẹ-rĭ′nŭm)

"A principle obtained from elaterium, a substance deposited by the juice of the fruit of *Ecballium Elaterium* (Linné) A. Richard (Fam. *Cucurbitaceæ*)." *U. S.*

Elaterine, Elatine, *Fr.;* Elaterin, *G;* Elaterina, *Sp.*

Preparation.—Elaterin was introduced into the U. S. Pharmacopœia on account of the well-known variability in quality of commercial elaterium. (See *Elaterium,* Part II.) Care must be taken to examine the elaterin, which is itself liable to be adulterated. It may be procured by evaporating an alcoholic tincture of elaterium to the consistence of thin oil, and throwing the residue while yet warm into a weak boiling solution of potassium hydroxide, this holds the green resin in solution, and the elaterin crystallizes as the liquor cools. Hennell obtained it by treating with ether the alcoholic extract procured by the spontaneous evaporation of the tincture. This consists of elaterin and the green resin, the latter of which, being much more soluble in ether than the former, is completely extracted by this fluid, leaving the elaterin pure. But, as elaterin is also slightly soluble in ether, a portion of this principle is wasted by Hennell's method. By evaporating the ethereal solution, the green resin is obtained separate. Hennell says that this was found to possess the purgative property of elaterium, as it acted powerfully in a dose of less than one-third of a grain. But the effect was probably owing to the presence of a portion of elaterin which had been dissolved by the ether. Flückiger prefers to exhaust elaterium with chloroform, and add to the percolate ether, which precipitates elaterin. The precipitate may be dissolved in chloroform and recrystallized. This process was adopted by the Br. Pharm., 1885.

Properties.—It is in "minute, white, hexagonal scales or prismatic crystals; odorless, and having a slightly acrid, bitter taste; permanent in the air. One Gm. of Elaterin dissolves in 325 mils of alcohol, 15.5 mils of chloroform, 450 mils of ether, and in 310 mils of benzene at 25° C. (77° F.); also in 100 mils of boiling alcohol; it is insoluble in either cold or hot water. Its alcoholic solution is neutral to moistened litmus paper. Mix about 0.01 Gm. of Elaterin with 1 mil of sulphuric acid; only a yellow color is produced (*readily carbonizable impurities*). On the addition of a drop of solution of formaldehyde the mixture becomes brown. A solution of about 0.01 Gm. of Elaterin in 5 mils of melted phenol becomes crimson on the addition of a few drops of sulphuric acid and rapidly changes to scarlet. No weighable ash remains on incinerating 0.1 Gm. of Elaterin. Shake about 0.1 Gm. of Elaterin with a mixture of 9 mils of distilled water and 1 mil of diluted hydrochloric acid and filter; separate portions of the filtrate yield no turbidity with 0.5 mil of mercuric potassium iodide T.S. or with iodine T.S. (*alkaloids*)." *U. S.*

Ernst Johannson (*In. Dis.,* Dorpat, 1884) gives the following reactions for elaterin besides those mentioned in the Pharmacopœia. In all of them elaterin is held in alcoholic solution. Froehde's reagent gives a green color passing into brown which fades away. Vanadin sulphuric acid with the fortieth of a milligramme produced a splendid blue color passing into a clear green, finally into reddish-brown. After mixing with selenic acid and an addition of sulphuric acid, in a few minutes a red-brown color develops, which is not so deep as that which is produced by sulphuric acid. Kohler's reaction is produced by dissolving elaterin in a few drops of concentrated hydrochloric acid, evaporating the acid in a water bath, washing the white, amorphous residue with boiling water, and adding some concentrated sulphuric acid, when an

amaranth-red color develops. By means of these reactions Johannson has been able to find elaterin in large quantities in the fæces of animals poisoned by it, but no trace in the blood or urine or any part of the organism.

Morries obtained 26 per cent. from the best British elaterium, 15 per cent. from the worst, and only 5 or 6 per cent. from the French, while a portion procured according to the directions of the London College yielded to Hennell upwards of 40 per cent. The Br. Pharmacopœia directs that the proportion of elaterin should not be less than 20 per cent. Experiments by John Williams satisfactorily prove that the fruit, exhausted of the free juice from which elaterium is obtained, contains very little if any elaterin, certainly not enough to compensate for the cost of its extraction. (*Chem. News*, 1860, p. 124.) According to Power and Moore (*Tr. Ch. Soc.*, xcvii, p. 99), elaterin consists of two isomeric substances, one lævorotary and physiologically inert, the active compound being dextrorotary. These they designate respectively as *alpha-* and *beta-elaterin*.

Uses.—Elaterin represents all the activities of elaterium; to which it is preferable on account of the greater uniformity of its effects.

Dose, one-twentieth to one-tenth of a grain (0.003–0.006 Gm.).

Off. Prep.—Trituratio Elaterini, *U. S.*

ELIXIR AROMATICUM. U. S.

AROMATIC ELIXIR Elix. Arom. [Simple Elixir]

(ēlĭx'ĭr ăr-ǫ-măt'ĭ-cŭm)

Elixir aromatique, *Fr.*; Aromatisches Elixir, *G.*

* "Compound Spirit of Orange, *twelve mils* [or 195 minims]; Syrup, *three hundred and seventy-five mils* [or 12 fluidounces, 326 minims]; Purified Talc, *thirty grammes* [or 1 ounce av., 25 grains]; Alcohol, Distilled Water, each, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. To the Compound Spirit of Orange add enough Alcohol to make *two hundred and fifty mils* [or 8 fluidounces, 218 minims]. To this solution, add the Syrup in several portions, agitating after each addition, and afterwards add, in the same manner, *three hundred and seventy-five mils* [or 12 fluidounces, 326 minims] of Distilled Water. Mix the Purified Talc intimately with the liquid, and then filter through a wetted filter, returning the first portions of the filtrate until a transparent liquid is obtained. Lastly, wash the filter with a mixture of *one volume* of Alcohol and *three volumes* of Distilled Water, until the product measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is justly one of the most popular vehicles of the Pharmacopœia. The flavor which is agreeable to nearly all palates is enhanced by its sweetness. If desired it can be colored with cochineal or caramel.

Off. Prep.—Elixir Aromaticum Rubrum, *N. F.*

ELIXIR GLYCYRRHIZÆ. U. S.

ELIXIR OF GLYCYRRHIZA Elix. Glycyrrh. [Elixir Adjuvans, U. S. VIII Elixir of Licorice]

(ēlĭx'ĭr glĭç-ĭr-rhī'zæ)

Adjuvant Elixir, Elixir adjuvant, *Fr.*; Gewürzhaftes Lakritzenelixir, *G.*

* "Fluidextract of Glycyrrhiza, *one hundred and twenty-five mils* [or 4 fluidounces, 109 minims]; Aromatic Elixir, *eight hundred and seventy-five millilitres* [or 29 fluidounces, 282 minims], to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix and filter." *U. S.*

Uses.—This elixir is used as a vehicle for the administration of various medicinal preparations; it was introduced into the U. S. Pharmacopœia (8th Rev.) mainly to furnish an alternative elixir to aromatic elixir which is similarly used. The presence of the glycyrrhiza aids in disguising or obtunding the taste of bitter or disagreeable substances and the proportion might advantageously be increased.

ELIXIRIA

ELIXIRS

(ēl-ĭx-ĭr'ĭ-ą)

Cordials; Elixirs, *Fr.*; Elixire, *G.*

Elixirs as they are known in modern American pharmacy are aromatic, sweetened, spirituous preparations, containing small quantities of active medicinal substances. They differ greatly from the liquids formerly termed elixirs, from the fact that the first object sought for in the modern elixir is an agreeable taste, and usually this is attained only by such sacrifices as to render the effect of the medicine almost *nil*, while the principal activity is due to the alcohol, which has proved in many cases very injurious. These considerations have prevented an extensive official recognition of elixirs, and the U. S. Pharm., 1890, recognized but two, one of which, the Aromatic Elixir, has been introduced merely as a vehicle. In the U. S. P. (8th Rev.) two elixirs were introduced, Adjuvant Elixir and Elixir of Iron, Quinine and Strychnine Phosphates. In the U. S. P. IX Elixir of Iron, Quinine and Strychnine Phosphates was dropped and Aromatic Elixir and Elixir of Glycyrrhiza (formerly named Adjuvant Elixir) were alone retained.

A number are, however, included in the N. F. IV. Elixir of Orange, official in the U. S. Pharm., 1880, may be made by the formula on page 435, *U. S. Dispensatory*, 19th edition.

EMBELIA. Br.

EMBELIA

(ĕm-bē'lĭ-ą)

"*Embelia* is the dried fruit of Embelia Ribes, *Burm. fil.*, and also of Embelia robusta, *Roxb.*" *Br.*

Embelia was introduced into the Br. Pharm. (1914) from the British Addendum (1900). It is officially described as "globular, about four

millimetres in diameter, varying in color from dull red to nearly black; warty or striated longitudinally; superior, minutely beaked and often attached to a 5-partite calyx and slender pedicel. Pericarp brittle, enclosing a single seed surrounded by a delicate membrane. Seed reddish, marked with lighter spots. Endosperm horny and slightly ruminated. Taste slightly astringent and aromatic." *Br.*

The genus *Embelia* (Fam. *Myrsinaceæ*) includes a large number of creeping or almost climbing tropical shrubs. They possess petiolate leaves, small white flowers and are especially abundant in tropical Asia, *Embelia Ribes* extending as far as southern China. The fruits of this plant somewhat resemble pepper and have been used as an adulterant of it.

Embelia contains 2.5 per cent. of *embelic acid*, $C_9H_{14}O_2$, which occurs in golden yellow crystals, which are insoluble in water and soluble in alcohol, ether, chloroform and benzene.

Uses.—Embelia, under the names of *viranga, vayvirang* or *birang-i-kabuli*, has long been employed in India as an anthelmintic and has found its way into European commerce. It has but slight laxative properties, so that it is better to follow it by a purgative. It is especially tenicidal, the *tape worm* being expelled dead. The powdered drug may be given in milk early in the morning. Warden has found that *ammonium embelate* is an effective tenicide in dose of three grains (0.2 Gm.) for children and six grains (0.4 Gm.) or more for adults. As it is nearly tasteless and soluble it may be readily administered in syrup.

Dose, of embelia, one to four drachms (3.9–15.5 Gm.).

EMETINÆ HYDROCHLORIDUM. U. S.

EMETINE HYDROCHLORIDE Emet. Hydrochl.

(ĕm'ē-tī-næ hȳ-drọ-ghlō'rī-dŭm)

"The hydrochloride [$C_{30}H_{44}O_4N_2.2HCl = 569.31$] of the alkaloid emetine, obtained from ipecac. It contains variable amounts of water of crystallization. Preserve it in dark amber-colored vials protected from light." *U. S.*

This alkaloidal salt was introduced into the U. S. P. IX. It is made by dissolving emetine in diluted hydrochloric acid, concentrating the solution and separating the crystals. It should be free from cephaeline. It is officially described as follows: "Emetine Hydrochloride occurs as a white or very slightly yellowish crystalline powder, without odor. On exposure to light it gradually darkens. Emetine Hydrochloride is freely soluble in water or alcohol. Its aqueous solution (1 in 20) is slightly acid to litmus. Separate portions of an aqueous solution of the salt (1 in 100) yield precipitates with iodine T.S., mercuric potassium iodide T.S., and with platinic chloride T.S. Sulphuric acid, containing in each mil about 0.005 Gm. of molybdic acid, when added to Emetine Hydrochloride produces a bright green color. Silver nitrate T.S. produces in an aqueous solution of the salt (1 in 20) a white precipitate insoluble in nitric acid. Dried to constant weight at 100° C. (212° F.), it loses not more than 19 per cent. of its weight. No weighable ash remains on incinerating 0.2 Gm. of Emetine Hydrochloride. One-tenth of 1 Gm. of the salt dissolves in 2 mils of sulphuric acid without producing more than a faintly yellow color (*readily carbonizable impurities*). Dissolve 0.1 Gm. of Emetine Hydrochloride in 5 mils of distilled water in a separatory funnel, add to the solution 3 mils of sodium hydroxide T.S. and shake it out with 10 mil portions of ether until the residue obtained by evaporating 1 mil of the ethereal liquid, when dissolved in 1 drop of diluted hydrochloric acid and 1 mil of distilled water, no longer yields a turbidity with iodine T.S. Now acidulate the aqueous liquid with diluted sulphuric acid, then add ammonia water until alkaline and shake it with 10 mils of ether. Evaporate this ethereal liquid and add to the residue 1 mil of sulphuric acid containing about 0.005 Gm. of molybdic acid; no purple color is produced (*cephaeline*)." *U. S.*

For further discussion of the properties see *Ipecacuanha.*

Uses.—Emetine hydrochloride is used, hypodermically, in the treatment of amebic *dysentery* and similar disorders in which ipecac is useful (see *Ipecacuanha*).

Dose, one-fourth to one-half grain (0.015–0.03 Gm.)

EMPLASTRA

PLASTERS

(ĕm-plăs'trą)

Emplâtres, *Fr.*; Pflaster, *G.*; Empiastri, *It.*; Emplastos, *Sp.*

Plasters are solid compounds intended for external application, adhesive at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them. Spread plasters having rubber in their composition are most largely used; they are usually perforated. Some plasters have as their basis a compound of olive oil and litharge, constituting the Emplastrum Plumbi of the Pharmacopœias. Others owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and fats.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the preparation may in any degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and, after being spread, should remain soft, pliable, and adhesive, without melting, at the heat of the human body. When long kept, they are apt to change color and to become hard and brittle, and, as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be excluded as much as possible. The defect may

usually be remedied by melting the plaster with a moderate heat and adding a sufficient quantity of oil to give it the due consistence.

Plasters are prepared for use by spreading them upon leather, linen, or muslin, according to the particular purposes they are intended to answer. Leather is most convenient when the application is made to the sound skin, linen or muslin when the plaster is used as a dressing to ulcerated or abraded surfaces, or with the view of bringing and retaining together the sides of wounds. The leather usually preferred is white sheepskin, or the kind known commercially as "hemlock splits." A margin about one-fourth or half an inch broad should usually be left uncovered, in order to facilitate the removal of the plaster, and to prevent the clothing in contact with its edges from being soiled. An accurate outline may be obtained by pasting upon the leather a piece of paper so cut as to leave in the center a vacant space of the required dimensions, and removing the paper when no longer needed. The spreading of the plaster is most conveniently accomplished by the use of a spatula or plaster iron. This may be heated by means of a spirit lamp or gas jet. Care must be taken that the instrument be not so hot as to discolor or decompose the plaster, and special care is requisite in the case of those plasters which contain a volatile ingredient. A sufficient portion of the plaster should first be melted by the heated instrument, and, having been received on a piece of coarse stiff paper, or in a shallow tin tray open on one side, should, when nearly cool, be transferred to the leather, and applied quickly and evenly over its surface. By this plan the melted plaster is prevented from penetrating the leather, as it is apt to do when applied too hot. Before removing the paper from the edge of the plaster, if this has become so hard as to crack, the iron should be drawn over the line of junction.

The spreading of plasters has become to a great extent a lost art to the pharmacists of this country, owing to the introduction of machine-spread plasters, which contain India-rubber in the adhesive composition. These are reasonably permanent, and do not require the application of heat. When made by reliable manufacturers they are in many cases to be preferred, but the introduction of immense quantities of worthless ones by unscrupulous makers has caused many practitioners to direct plasters to be spread by the pharmacist from official plaster. The perforation, or "porousing," of plasters is usually accomplished on a large scale by expensive apparatus. J. J. Edmondson read a paper before the Pennsylvania Pharmaceutical Association in 1887 giving the process for manufacturing rubber-mass plasters as carried on by Johnson & Johnson, of New York. It is as follows: The ingredients employed are—rubber, two parts; Burgundy pitch, one part, gum olibanum, one part. This may vary with some special plasters, but they constitute the component parts of the mass used for the majority.

The crude rubber is at first steeped in hot water, to cleanse and soften it, then the rubber is passed through the washer and crusher, where it is subjected to severe pressure between two corrugated rolls, eight inches in diameter and one foot wide, while a stream of water falling continually washes it thoroughly, and it comes out in sheets somewhat softened. After these sheets are dried, which requires a number of days, they are passed through the grinder, where they are crushed between two smooth rollers, fourteen inches in diameter and thirty-six inches across. This thoroughly softens the rubber and makes it plastic, so that it can be readily worked up with the other ingredients. The principal operation, the mixing, then takes place. The medication must be carefully combined, and the whole manipulation so managed that the plaster will be uniform, so that age or varying temperature shall not affect it. This operation is performed by means of rollers, sixteen inches in diameter, arranged so that one revolves at twice the speed of the other. Between these large rollers the mass is passed with whatever medication is required: *e.g.*, when a belladonna mass is to be made, a certain amount of the stock mass is taken and extract of belladonna in the proportions corresponding to the formula in the Pharmacopœia. These are repeatedly passed through the rollers until the extract of belladonna is thoroughly mixed with the mass, care being taken to keep the temperature from rising high enough to decompose or affect the alkaloids. The spreading is also done by rollers, into which the thoroughly mixed mass is fed at the same time that the cloth is fed, the thickness of the plasters being governed by the adjusting of screws on the side of the machine.

The rubber base is pliable, adhesive, it will not become too hard or too soft, but will yield up the medication to the absorbents of the skin, and its properties will be retained indefinitely. For formulas for plasters of former Pharmacopœias, see *U. S. D.*, 19th edition, p. 436.

EMPLASTRUM BELLADONNÆ. U. S., Br.

BELLADONNA PLASTER Emp. Bellad.

(ĕm-plăs'trŭm bĕl-la-dŏn'næ)

"An adhesive plaster containing 30 per cent. of extract of belladonna leaves and yielding not less than 0.35 per cent. nor more than 0.40 per cent. of the alkaloids from belladonna leaves." *U. S.*

Emplâtre de Belladone, *Fr.*; Belladonna-Pflaster, *G.*; Emplasto de belladonna, *Sp.*

"Liquid Extract of Belladonna, 50.0 *millilitres;* Resin Plaster, 137.5 *grammes.* Concentrate the Liquid Extract of Belladonna by evaporation at a low temperature until it is reduced in weight to *twelve and a half grammes;* add the Resin Plaster, previously melted; mix. This Plaster contains 0.25 per cent. of the alkaloids of Belladonna Root, and is of one-half the strength of the Emplastrum Belladonnæ of the British Pharmacopœia, 1898." *Br.*

No process is given in the U. S. P. IX for

making Belladonna plaster. It is now made almost exclusively with a rubber base by manufacturers on a large scale.

Assay of Belladonna Plaster. U. S. IX. —"Introduce 10 Gm. of Belladonna Plaster into a 100 mil flask. (If the plaster is spread on fabric, cut the portion to be assayed into strips, weigh it accurately, and introduce it into the flask.) Now add 50 mils of chloroform, and shake the mixture until the plaster is dissolved. Pour the chloroform solution into a 250 mil beaker and wash the cloth upon which the plaster was spread with two portions of 25 mils each of chloroform, adding the washings to the chloroform solution in the beaker. Then wash this cloth with 80 mils of alcohol containing 1 mil of ammonia water and pour the washings into the chloroform solution in the beaker. Stir the mixture gently and allow it to stand until the rubber has separated into a compact mass. Dry the cloth upon which the plaster was spread, weigh it and subtract its weight from the original weight of the plaster. Pour the chloroform-alcohol solution into a 350 mil separator, rinse the beaker and rubber with 10 mils of alcohol and add the rinsing to the separator. Then add to the separator 100 mils of distilled water, rotate until thoroughly mixed and allow it to stand until the liquids separate. Then draw off the chloroform into a second separator containing 50 mils of distilled water, shake it thoroughly and after separation draw off the chloroform into a beaker and pour the aqueous solution into the first separator. Return the chloroform solution to the second separator and shake out the contents of the first separator with two portions of 10 and 5 mils, respectively, of chloroform, adding them to the chloroform in the second separator. Completely extract the alkaloids from the chloroform solution by shaking it out repeatedly with weak sulphuric acid. Collect the acid washings in a separator and add ammonia water until the solution is decidedly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with chloroform. Filter the chloroform solution through a pledget of cotton, evaporate it to dryness and dissolve the alkaloids from the residue in exactly 5 mils of tenth-normal sulphuric acid V.S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., using cochineal T.S. as indicator (see Proximate Assays, Part III). Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the alkaloids from belladonna leaves." *U. S.*

This plaster was formerly prepared, in both Pharmacopœias, with the extract made from the inspissated juice of the leaves, but in the U. S. P., 1880, an alcoholic extract of the root was substituted, with the effect of rendering the plaster easier to be spread and more adhesive, and giving it a light yellowish-brown color, without a shade of green. The official preparation is now of a brownish-green color, due to the extract of belladonna leaves. It is a useful anodyne application in *neuralgic* and *rheumatic pains*. We have seen the constitutional effects of belladonna result from its external use. T. W. Worthington proposed a formula for making belladonna plaster with caoutchouc in the *A. J. P.*, xliii, 153. Machine-spread belladonna plasters have been found in the market which were admitted by a representative of the manufacturer to contain no extract of belladonna whatever. For methods of assaying belladonna plasters, see *A. J. P.*, 1898, 182, 293. *Extract of scopola* has been largely used by manufacturers in making rubber base belladonna plaster.

EMPLASTRUM CALEFACIENS. Br.

WARMING PLASTER

(ĕm-plăs'trŭm căl-ę-fā'cį-ĕns)

Emplastrum Picis Cantharidatum, *U. S.* 1890; Warm Plaster; Emplâtre de Poix cantharide, *Fr.*; Pechpflaster mit Canthariden, *G.*

"Cantharidin, 0.2 *gramme;* Chloroform, 20.0 *millilitres;* Olive Oil, 40.0 *millilitres;* Resin Plaster, 940.0 *grammes.* Dissolve the Cantharidin in the Chloroform, add the Olive Oil, and mix with the Resin Plaster, previously melted on a water bath. This Plaster contains 0.02 per cent. of Cantharidin, which is approximately the proportion contained in the Emplastrum Calefaciens of the British Pharmacopœia, 1898." *Br.*

Cantharidal pitch plaster or warming plaster is not official in the U. S. P. IX; the process of the U. S. P., 1890, will be found on p. 439, *U. S. D.*, 19th edition. The use of the blistering principle cantharidin dissolved in chloroform and olive oil will undoubtedly prove to be an improvement over the older process.

This plaster is an excellent rubefacient, more active than Burgundy pitch, yet in general not sufficiently so to produce vesication.

Warming plaster is employed in *chronic rheumatism,* and in chronic internal diseases attended with inflammation, such as *catarrh, asthma, pertussis, phthisis, hepatitis,* and the sequelæ of *pleurisy* and *pneumonia.*

EMPLASTRUM CANTHARIDIS. U. S. (Br.)

CANTHARIDES PLASTER Emp. Canthar.

(ĕm-plăs'trŭm cạn-thăr'į-dīs)

Emplastrum Cantharidini, *Br.;* Cantharidin Plaster; Emplastrum Epispasticum, s. Vesicatorium, s. Vesicans, Emplastrum Lyttæ; Blistering Cerate or Plaster; Emplâtre Vesicatoire, *Fr. Cod.;* Pommade Épispastique, Emplâtre de Cantharides, *Fr.;* Emplastrum Cantharidum Ordinarium, *P. G.;* Spanischfliegen Pflaster, Blasenpflaster, *G.;* Pomata di cantaridi, *It.;* Unguento de cantharidas, *Sp.*

In the British Pharm., 1914, the name of this plaster was changed to "cantharidin plaster" because it is now made from the blistering principle instead of from the powdered flies or the cerate.

* "Cantharides Cerate, Rosin Plaster, spread on fabric, each, *a sufficient quantity.* Spread cantharides cerate upon rosin plaster, leaving a margin around the edges. It may also be spread on muslin, paper, or other suitable material. This plaster should not be dispensed unless it has been recently prepared. Each square centi-

meter of spread plaster contains 0.1 Gm. of cantharides cerate." *U. S.*

"Cantharidin, 2 *grammes;* Chloroform, 100 *millilitres;* Yellow Beeswax, 450 *grammes;* Wool Fat sufficient to produce 1000 *grammes.* Dissolve the Cantharidin in the Chloroform by the aid of heat, add to the other ingredients previously melted on a water-bath, and stir until cold. This Plaster contains 0.2 per cent. of Cantharidin, which is approximately the proportion contained in the Emplastrum Cantharidis of the British Pharmacopœia, 1898." *Br.*

Uses.—See *Ceratum Cantharidis* (page 313) and *Cantharis* (page 285).

EMPLASTRUM CAPSICI. U. S.

CAPSICUM PLASTER Emp. Capsic.

(ĕm-plăs'trŭm căp'sĭ-cī)

Sparadrapum Capsici; Sparadrap de Capsique, *Fr.;* Capsicumpflaster, *G.*

* "Oleoresin of Capsicum, Rubber Plaster, spread on fabric, each, *a sufficient quantity.* Apply oleoresin of capsicum to the surface of rubber plaster so as to form a thin, even coating, leaving a margin around the edges. Each fifteen square centimeters of spread plaster contains 0.25 Gm. of oleoresin of capsicum." *U. S.*

The oleoresin should be laid on very evenly with a camel's-hair brush.

This affords a convenient way of obtaining the rubefacient effects of capsicum; of course, the practice will be for the pharmacist to employ machine-spread adhesive plaster as the base; although, with a little experience, very good work can be done by hand.

EMPLASTRUM ELASTICUM. U. S.

RUBBER PLASTER Emp. Elast. [Rubber Adhesive Plaster]

(ĕm-plăs'trŭm ę-lăs'tĭ-cŭm)

"A mixture of rubber, resins and waxes, with a filler of an absorbent powder, such as orris root or starch, mechanically mixed and spread upon cotton cloth or other fabric." *U. S.*

Rubber Plaster as above defined is used throughout the world and is made by special machinery on a large scale. It has superseded hand spread adhesive plaster.

EMPLASTRUM HYDRARGYRI. Br.

MERCURIAL PLASTER

(ĕm-plăs'trŭm hȳ-drär'gy-rī)

Emplastrum Mercuriale; Emplâtre mercurial, *Fr. Cod.;* Emplastrum Hydrargyri, *P. G.;* Quecksilberpflaster, *G.;* Empiastro mercuriale, *It.*

"Mercury, 328 *grammes;* Olive Oil, 18 *grammes;* Sublimed Sulphur, 2 *grammes;* Lead Plaster, 652 *grammes.* Heat the Olive Oil with the Sulphur until a reddish-brown liquid is obtained; with this solution triturate the Mercury until metallic globules are no longer visible; add the Lead Plaster, previously melted; mix." *Br.*

Mercurial plaster is no longer official in the U. S. P. IX. The U. S. Pharm. VIII employed oleate of mercury and hydrous wool-fat for the purpose of extinguishing the mercury; this it does effectually, and at the same time increases the efficiency of the mercurial constituent. The quantity of mercury was 30 per cent. The British preparation is stronger, containing 32.8 per cent.

The former U. S. and British processes may be considered identical in their results. Thomas Blunt has found it almost impossible to divide the mercury sufficiently by trituration with oil and rosin, and the resulting plaster was so crumbly that it could not be formed into rolls; but on substituting a weight of Venice turpentine equal to that of the oil and rosin combined, he found it to answer completely. An objection, however, to the turpentine is, that it might render the plaster too irritant for susceptible skins. (*P. J.*, 1864, p. 56.) For methods of assaying this plaster, see *A. J. P.*, 1911, p. 314; *C. D.*, 1911, p. 631; *P. J.*, 1911, p. 654.

Uses.—This plaster is employed to produce the local effects of mercury upon *syphilitic* lesions of the skin and other chronic tumefactions of the bones or soft parts, dependent on a syphilitic taint. It occasionally affects the gums.

From observations made in France by Serres and others, it appears that the mercurial plaster of the Codex (*Emplastrum* (*Emplâtre*) *de Vigo cum Mercurio*), see *U. S. D.*, 19th edition, p. 440, has the power, when applied over the eruption of *small pox,* before the end of the third day from its first appearance, to check its progress and prevent suppuration and pitting. This operation of the plaster, so far from being attended with an increase of the general symptoms, seems to relieve them in proportion to the diminution of the local affection. That the local effect is not ascribable to the mere exclusion of the air is proved by the fact that the use of lead plaster was not followed by the same results. It is probable that other mercurial preparations would answer the same purpose.

EMPLASTRUM MENTHOL. Br.

MENTHOL PLASTER

(ĕm-plăs'trŭm mĕn'thŏl)

Emplâtre de Menthol, *Fr.;* Mentholpflaster, *G.*

"Menthol, 150 *grammes;* Yellow Beeswax, 100 *grammes;* Resin, 750 *grammes.* Melt the Beeswax and Resin together; when the mixture has cooled to about 70° C. (158° F.), add the Menthol, and stir until dissolved." *Br.*

This is an official plaster of the British Pharmacopœia, having been introduced in the additions in 1885. It is a mild counter-irritant, intended especially for relief in localized *neuralgia* and *rheumatic pains.*

EMPLASTRUM PLUMBI. U. S., Br.

LEAD PLASTER Emp. Plumb. [Diachylon Plaster]

(ĕm-plăs'trŭm plŭm'bī)

Emplastrum Lithargyri, *Br.* 1864; Emplastrum Diachylon Simplex, Emplastrum Album Coctum; Litharge Plaster; Emplâtre simple, *Fr. Cod.;* Emplâtre de Plomb (de Litharge), Emplastrum simplex, *Fr.;* Emplastrum Lithargyri (simplex), *P. G.;* Emplastrum Cerussæ, Froschlaichpflaster; Bleipflaster, Diachylonpflaster, *G.;* Empiastro diachilon, *It.;* Emplasto de plomo simple, Emplasto simple, *Sp.*

* "Lead Oxide, *one thousand grammes* [or 35 ounces av., 120 grains]; Olive Oil, *one thousand grammes* [or 35 ounces av., 120 grains]; Lard, *one thousand grammes* [or 35 ounces av., 120 grains]; Boiling Water, *a sufficient quantity.* Heat the olive oil and lard by a gentle heat until liquefied in a bright copper or other suitable vessel of a capacity of not less than four times the bulk of the ingredients, sift the lead oxide, through a No. 80 sieve, upon the surface of the hot liquid and mix thoroughly. Then gradually add *three hundred and fifty mils* [or 11 fluid-ounces, 401 minims] of boiling water, and boil the mixture, constantly stirring, with a wooden spatula, and adding sufficient boiling water, from time to time, to replace that lost by evaporation, until the mass is homogeneous and a small portion removed and dipped into cold water is found to be pliable and tenacious. Then remove it from the fire and wash several times with warm water to remove the glycerin. Finally knead the mass until it is free from water, roll it into cylinders of suitable size, and wrap them in paper." *U. S.*

"Lead Oxide, 400 *grammes;* Olive Oil, 800 *grammes;* Distilled Water, 400 *millilitres,* or *a sufficient quantity.* Boil gently together in a steam-bath, stirring constantly until combination has been effected. When cool remove the plaster-like mass produced; knead it thoroughly with hot water, and allow it to dry." *Br.*

The importance of this plaster, as the basis of many other plasters, requires a somewhat detailed account of the principles and manner of its preparation. A very important change was made in the process for lead plaster in the U. S. Pharmacopœia VIII. The method of boiling litharge, olive oil, and water together, which is still official in the British Pharmacopœia, was discarded and the precipitation method introduced. The resulting product was chemically nearly identical with that made by the boiling process and is much whiter in color, while the adhesiveness of the present plaster seemed to be superior to that of the U. S. P., 1890, but experience has proved that the precipitation method produces a plaster which does not keep as well as did the plaster made in the old way, hence the U. S. P. IX has returned to the former process, although the olive oil is partially replaced by lard.

The reaction in the U. S. P. VIII process, disregarding the palmitin present, was as follows:

$$\underset{\text{Sodium oleate}}{2NaC_{18}H_{33}O_2} + \underset{\text{Lead acetate}}{Pb(C_2H_3O_2)_2} = \underset{\text{Lead oleate}}{Pb(C_{18}H_{33}O_2)_2} + \underset{\text{Sodium acetate}}{2NaC_2H_3O_2}$$

In the U. S. P. IX and the British process a reaction takes place between the oil and water, resulting in the development of glycerin, and of two acid bodies, oleic and palmitic acids, to which, when animal fat is employed instead of olive oil, a third is added—namely, stearic acid. The plaster is formed by a union of these acids with the oxide, and, prepared according to the directions of the Pharmacopœias, is in fact a lead oleo-palmitate, and if the olive oil contained stearin it would be a lead oleo-stearo-palmitate. The glycerin remains dissolved in the water, or mechanically mixed with the plaster. That such is the correct view of the nature of this compound is evinced by the fact that, if the lead oxide be separated from the plaster by digestion at a moderate heat in very dilute nitric acid, the fatty matter which remains will unite with litharge with the greatest facility, without the intervention of water. The fixed or fatty oils are compounds of the free fatty acids mentioned and the radical glyceryl. When boiled with the lead oxide and water, the fatty acids combine with the metallic oxide to form the plaster, and the glyceryl unites with the hydroxyl and becomes glycerin. The British process does not provide for the separation of the glycerin and the plaster is not kneaded to separate the water, both of which, in our opinion, are necessary to produce the best result and which form part of the U. S. P. IX process.

The reaction between olein and lead oxide is as follows:

$$\underset{\text{Olein}}{2C_3H_5(C_{18}H_{33}O_2)_3} + \underset{\text{Litharge}}{3PbO} + \underset{\text{Water}}{3H_2O} = \underset{\text{Lead oleate}}{3Pb(C_{18}H_{33}O_2)_2} + \underset{\text{Glycerin}}{2C_3H_5(OH)_3}$$

Other oleaginous substances and other metallic oxides are susceptible of the same combination, and some of them form compounds having the consistence of a plaster; but, according to Henry, of Paris, no oily matter except animal fat can properly be substituted for olive oil, and no metallic oxide, not even one of the other oxides of lead, for litharge. He ascertained, moreover, that the English litharge is preferable for the formation of lead plaster to the German. From experiments of Soubeiran, it appears that yellow lead oxide or even red lead oxide may be substituted for litharge, and a plaster of good consistence be obtained, but that a much longer time is required for completing the process than when the official formula is followed. Owing to the necessity for its partial deoxidation, the use of yellow lead oxide requires a longer continuance of the process than when litharge is employed. According to Davallon, it is important that the olive oil employed should be pure, for when adulterated, as it frequently is, it yields an imperfect product.

N. S. Thomas prepared a good plaster by substituting lard for olive oil, in the proportion of eight pounds of lard to five of litharge (*A. J. P.,* xix, 175), and we are told that it is a common practice in this country to make lead plaster with a mixture of lard oil and olive oil. Mueller uses equal parts of lard, olive oil, and litharge, having previously heated the litharge until a small sample causes no effervescence when dropped into nitric acid, showing the absence of carbonate. (*Ph. Ztg.,* 1879, p. 70; *A. J. P.,* 1879, p. 190.) It is said that the Eng-

lish plaster makers rarely follow the Br. Pharm. direction, preferring the recipe of the old London Pharmacopœia, which contains more litharge and yields a much firmer and less adhesive product. (*P. J.*, 3d ser., p. 701, 716.)

Zinc Plaster.—De Mussey, having witnessed inconveniences from lead plaster in consequence of the absorption of the lead, substituted for it a plaster with a basis of zinc oxide, which he has found to answer very well in practice. It cannot be made by direct combination of the oxide, and it is necessary to have recourse to the method of double decomposition. Solutions of white olive oil soap and of zinc sulphate being mixed, a copious precipitate takes place of zinc oleopalmitate, which, after being washed and dried, may be combined with resins, oil, and wax, to give it the necessary consistence.

The process of the United States Pharmacopœia VIII by precipitation is well adapted for making comparatively small quantities of lead plaster, but manufacturers prefer the boiling process when large quantities are to be made, and the following details are retained: The vessel in which the lead plaster is prepared should be of such a size that the materials will not occupy more than two-thirds of its capacity. The oil should be first introduced, and the litharge then sprinkled in by means of a sieve, the mixture being constantly stirred with a spatula. The particles of the oxide are thus prevented from coalescing in small masses, which the oil would not easily penetrate, and which would, therefore, delay the process. While the water exerts an important chemical agency in the changes which occur, it is also useful by preventing too high a temperature, which would decompose the oil, and cause the reduction of the oxide. The waste must, therefore, be supplied by fresh additions as directed in the process, and the water added for this purpose should be previously heated, as otherwise it would not only delay the operation, but by producing explosion might endanger the operator.

During the continuance of the boiling, the material should be constantly stirred, and the spatula should be repeatedly passed along the bottom of the vessel, from side to side so as to prevent any of the oxide, which is disposed by its greater density to sink to the bottom, from remaining in that situation. The materials swell up considerably, in consequence partly of the vaporization of the water, partly of the escape of carbon dioxide, which is liberated by the oily acids from some lead carbonate usually contained in the litharge. The process should not be continued longer than is sufficient to produce complete union of the ingredients, and this may be known by the color and consistence of the mass. The color of the litharge gradually becomes paler, and at length almost white when the plaster is fully formed. The consistence increases with the progress of the boiling, and is sufficiently thick when a portion of the plaster, taken out and allowed to cool upon the end of a spatula, or thrown into cold water, becomes solid, without adhering in this state to the fingers. The portion thus solidified should not present, when broken, any red spots, which would indicate the presence of a portion of uncombined litharge. When the plaster is formed, it should be removed from the fire, and after a short time cold water should be poured upon it. Portions should then be detached from the mass, and, having been well kneaded under water, in order to separate the viscid solution of glycerin contained in the interior, should be formed into cylindrical rolls, and wrapped in paper. Such, at least, has been the course of proceeding usually recommended. But Davallon maintains that the presence of glycerin in the plaster is useful by keeping it in a plastic state, and that washing and kneading are injurious, the former by removing the glycerin, the latter by introducing particles of air and moisture into the mass, which is thus rendered more disposed to rancidity. (*A. J. P.*, xv, 274; from *Journ. de Chim. Méd.*) By employing steam heat in the preparation of this plaster, the risk of burning it is avoided. Bernbeck found that lead plaster could be preserved from hardening and oxidation if kept in air tight canisters. (*Ph. Ztg.*, 1881, p. 589.)

Uses.—This plaster, which has long been known under the name of *diachylon,* is used as an application to excoriated surfaces and to slight wounds, which it serves to protect from the action of the air. It may also be beneficial by the sedative influence of the lead which enters into its composition. A case is on record in which lead colic resulted from its long continued application to a large ulcer of the leg. (*Am. J. M. S.*, xxiii, 246.) J. M. Bigelow reports a case of excessive sweating of the feet cured by putting the patient in bed for thirteen days and keeping the feet enveloped in strips of lead plaster. (*N. R.*, Oct., 1875.) Its chief use is in the preparation of other plasters. See *Logan's Plaster, Mahy's Plaster, U. S. D.*, 19th edition, p. 443.

EMPLASTRUM RESINÆ. U. S., Br.

ROSIN PLASTER Emp. Res. [Rosin Adhesive Plaster, Adhesive Plaster]

(ĕm-plăs'trŭm rẹ-sĭn'æ)

Resin Plaster, *Br.;* Emplâtre Adhésif, Emplâtre Résineux, *Fr.;* Emplastrum adhæsivum, *P. G.;* Heftpflaster, *G.;* Emplastro adesivo, *It.*

* "Rosin, in fine powder, *one hundred and forty grammes* [or 4 ounces av., 411 grains]; Lead Plaster, *eight hundred grammes* [or 28 ounces av., 96 grains]; Yellow Wax, *sixty grammes* [or 2 ounces av., 51 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the lead plaster and yellow wax together with a gentle heat, then add the rosin and, when melted, mix thoroughly, strain, and

allow the product to cool, stirring until it stiffens." *U. S.*

"Resin, 100 *grammes;* Lead Plaster, 850 *grammes;* Hard Soap, 50 *grammes.* Melt each ingredient separately at as low a temperature as possible; mix." *Br.*

The name of this plaster was changed in the U. S. P. IX to rosin plaster, it was formerly termed adhesive plaster. It differs from lead plaster in being more adhesive and somewhat more stimulating. It resembles the common adhesive plaster of commerce, and is much employed for retaining the sides of wounds in contact, and for dressing ulcers according to the method of Baynton, by which the edges are drawn towards each other and a firm support is given to the granulations. The U. S. P. IX formula differs from that official in U. S. P. VIII in that the use of rubber and petrolatum in place of yellow wax and rosin was abandoned and the old process has been restored. As prepared by the Dublin College it contained soap, which gave it greater pliability, and rendered it less liable to crack in cold weather, without impairing its adhesiveness, and the process of that College has been adopted in the British Pharmacopœia. It is usually spread upon muslin, and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept ready spread by the pharmacist; but, as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed. Adhesive plaster originally employed by Baynton contained only six drachms of rosin to the pound of lead plaster. To obviate the possibility of irritating the skin, Herpin recommends the addition of lead tannate, the proportion of which, when adhesiveness is required in the plaster, should not exceed one-twentieth, but under other circumstances may be increased to one-twelfth.

The addition of Burgundy pitch or turpentine is objectionable, as they greatly increase the liability of the plaster to irritate the skin, and thus materially interfere with the purposes for which the preparation was chiefly intended.

The most popular and widely used forms of adhesive plaster used at the present time are those containing zinc oxide as one of the constituents.

EMPLASTRUM SINAPIS. U. S.

MUSTARD PLASTER Emp. Sinap. [Charta Sinapis, U. S. VIII, Mustard Paper]

(ĕm-plăs'trŭm sĭ-nā'pĭs)

"A uniform mixture of powdered black mustard (deprived of its fixed oil), and a solution of rubber, spread on paper, cotton cloth or other fabric. Preserve it in tightly-closed containers. A square of 100 square centimeters contains not less than 2.5 Gm. of black mustard deprived of its fixed oil. When moistened thoroughly with tepid water and applied to the skin, the Plaster produces a decided warmth and reddening of the skin within five minutes. Before Mustard Plaster is applied, moisten it thoroughly with tepid water." *U. S.*

Sinapisme en feuille, *Fr. Cod.;* Papier Moutarde, Papier Sinapisé, *Fr.;* Charta sinapisata, *P. G.;* Senf-papier, *G.;* Carta senapata, *It.;* Papel sinapico, Charta sinapica, *Sp.*

* "Black Mustard, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Rubber, *ten grammes* [or 154 grains]; Petroleum Benzin, Carbon Disulphide, each, *a sufficient quantity.* Pack the Black Mustard in a conical percolator, and gradually pour Petroleum Benzin upon it until the percolate ceases to produce a permanent, greasy stain upon blotting paper. Remove the powder from the percolator, and dry it by exposure to the air. Having meanwhile dissolved the Rubber in a mixture of *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], each, of Petroleum Benzin and Carbon Disulphide, mix the purified Mustard with a sufficient quantity of the solution to produce a semi-liquid magma, and apply this, by means of a suitable brush, to one side of a piece of rather thick, well-sized paper, so as to cover it completely, and then allow the surface to dry. A surface of sixty square centimeters should contain about 4 Gm. of Black Mustard deprived of oil. Before it is applied to the skin, Mustard Paper should be dipped in warm water for about fifteen seconds." *U. S. VIII.*

"Black and White Mustard Seeds, equal proportions by weight; Benzol, Solution of India-rubber, of each, a sufficient quantity. Bruise the Mustard Seeds and extract the fixed oil by percolation with the Benzol. Dry the residue by exposure to the air in a warm closet, and reduce to No. 60 powder. Mix seventy-five grains (or five grammes) of the purified mustard with five fluid drachms (or eighteen cubic centimetres) of Solution of India-rubber, and spread by means of a suitable brush over about 30 square inches (or about two square decimetres) of one side of a piece of cartridge paper. Allow it to dry by exposure to the air." *Br.,* 1898.

The name of this preparation was changed in the U. S. P. IX from mustard paper to mustard plaster; from a pharmaceutical point of view this was a mistake, for *mustard leaves* as they are often called are very different from either mustard plasters or mustard poultices. The U. S. P. IX and the British Pharm. (1914) no longer admit a process for making *Charta Sinapis,* the U. S. P. IX merely describing the preparation as found in commerce. The U. S. P. VIII and the Br. Pharm., 1898, processes are given above.

The formula for this preparation was greatly improved by the U. S. P. in 1890 and Br., 1898. The British preparation (1885) was at fault in not providing for the extraction of the fixed oil by previously percolating with petroleum benzin or carbon disulphide; otherwise the paper will be greasy, giving to the plaster an untidy appearance and soiling the linen of the patient. Solution of gutta-percha is unsuited for use in this preparation, on account of want

of adhesiveness, and the tendency of the mixture, when dry, to crack and peel off. We have used instead a solution of 1 part of pure rubber in 30 of equal parts of carbon disulphide and petroleum benzin. On the large scale, by means of a plaster spreading apparatus a uniform coat of this solution may be applied to paper. As the latter passes out from under the apparatus, a sieve containing the powdered mustard is shaken over it; this is fixed by the adhesive coat and firmly retained after the evaporation of the volatile liquids in a warm place. The application of the powdered mustard must be properly regulated according to the speed with which the machine delivers the coated paper. The paper is cut into pieces of convenient size, and needs only to be wetted with tepid water to be ready for use. Owing to the fact that the large manufacturers can put mustard paper upon the market at such low rates that it pays the apothecary better to buy than to prepare it, Charta Sinapis, so far as we can learn, is rarely made in the retail stores.

Uses.—For the uses of the mustard plaster, see *Sinapis*, p. 1010.

Experience has shown that the ready-made mustard papers err rather from too much than from too little activity. Moreover, their action cannot be regulated with the same nicety as can that of the mustard poultice. Unless in the case of travellers, and of others who must wait upon themselves, the domestic application is preferable. The *mustard leaves* can rarely be borne for more than ten or fifteen minutes. Care should be observed to protect the leaves, as they are popularly called, from the action of moist air by keeping them in well closed containers.

EMPLASTRUM SAPONIS. Br.

SOAP PLASTER

(ĕm-plăs'trŭm sa-pō'nĭs)

Emplâtre de Savon, *Fr. Cod.;* Emplastrum cum Sapone, *Fr.;* Emplastrum Saponatum, *P. G.;* Seifenpflaster, *G.;* Emplasto de jabon, *Sp.*

"Hard Soap, 140 *grammes;* Lead Plaster, 835 *grammes;* Resin, 25 *grammes.* Melt each ingredient separately at a low temperature; mix; evaporate, with constant stirring, to a proper consistence." *Br.*

* "Soap, dried, and in coarse powder, *ten grammes* [or 154 grains]; Lead Plaster, *ninety grammes* [or 3 ounces av., 76 grains]; Water, *a sufficient quantity,* to make about *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Soap with enough Water to reduce it to a semi-liquid state; then mix it with the Lead Plaster previously melted, incorporate thoroughly by stirring, and evaporate to the proper consistence." *U. S. VIII.* (See also *N. F. IV,* Part III.)

Soap plaster was not retained in the U. S. P. IX; it was transferred to the National Formulary IV. Soap plaster is considered discutient, and is sometimes used as an application to tumors, where a dressing is required. Somewhat softer in its character, the *soap cerate,* formerly official, may be found useful. This was made as follows: *Ceratum Saponis.* "Take of Soap Plaster *two troyounces;* White Wax *two troyounces and a half;* Olive Oil *four troyounces.* Melt together the Plaster and Wax, add the Oil, and, after continuing the heat a short time, stir the mixture until cool." *U. S.,* 1870.

EMULSA.

EMULSIONS

(ę-mŭl'sa)

Emulsions, *Fr.;* Emulsiones, *G.;* Emulsiones *It., Sp*

Under this head are included in the U. S. Pharmacopœia liquid preparations in which oleaginous substances are suspended in aqueous fluids by the intervention of gum or other viscid matter. The preparations forming the present class of emulsions were termed Mixtures in earlier pharmacopœias, and it is to be regretted that under this indefinite term are still grouped liquids of many kinds; the separation of these into proper classes is only a question of time, and the introduction of this new class into the Pharmacopœia of 1890 marked the first step in the direction of greater accuracy in defining pharmaceutical preparations, and more system in classification. The object of emulsions is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines, and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of uniform and perfect emulsions. As a rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the intermedium, before the aqueous vehicle is added. In the case of the liquid balsams and oils, if gum arabic is employed as the intermedium it should be previously brought to the state of mucilage of the consistence directed in the U. S. Pharmacopœia. When a fixed oil, oleoresin, or balsam is to be made into an emulsion, the method most employed abroad is to add one part of gum to two or three of the oil, in a mortar, triturate until the mixture is complete, and then add at once twice as much water as gum used, and triturate rapidly until the oil is completely emulsified, then gradually add the remainder of the vehicle with constant trituration. Agitation in a bottle is sometimes substituted for trituration. The plan most largely used in this country is to make the emulsion with mucilage. Having a broad flat pestle and a mortar perfectly free from grease, put in a little mucilage, rub it around the mortar, add about half as much oil, triturate from the center so as to emulsify this, then add more mucilage, then oil, and so on until the operation is completed. Care is required never to get the oil in excess of the mucilage. This plan seems to accord with the principle laid down by R. Rother, that the most perfect and rapid emulsifier is a perfect emul-

sion. The proportion of gum and water necessary to make a good emulsion with the fixed oils varies with the oil. Thus, while castor oil requires only two drachms of the gum and three drachms of water to the ounce, most other fixed oils require half their weight of gum, and a weight of water equal to half that of the oil and gum united. These quantities being well rubbed together, any desirable amount of water may afterwards be gradually added, and will readily incorporate with the other ingredients. The white of egg has been frequently ordered by physicians as the suspending substance, but it is inferior for this purpose to the yolk, or to gum arabic. When the white is used it should be well beaten, and incorporated with the oleaginous or balsamic substances before the water is added. When volatile oils are to be emulsified they should be mixed with an equal volume of inert fixed oil to promote stability. Quillaja, saponin, and other substances having similar properties have been proposed as emulsifying agents, but they are objectionable on account of their medicinal activity. Emulsifying agents should be inert.

Leo Roon (*J. A. Ph. A.*, 1916, v, 496) gives an extensive review of the literature on emulsification and Roon and Oesper have made an important contribution to the theory of emulsification (*J. I. & E. C.* 1917, p. 156). The authors agree with Fischer (*Science* 1916, p. 468) that emulsification is due to, or accompanied by, the formation of a hydrated colloid compound. Both the English and Continental methods of emulsification were studied carefully. The unsatisfactory results obtained by the majority of workers with the English method, are alleged to be due to the fact that the hydration of the emulsifying agent occurs progressively and not all at one time and for the greater part is not accomplished in the presence of the internal phase (oil). In the Continental method all of the emulsifying agent (colloid) is hydrated at one time and in the presence of the internal phase (oil). After experimenting with various proportions of materials, it is stated by the authors that the best and quickest results are obtained by the use of the following proportions in the preparation of the original nucleus: oil 4, water 3, gum 2.

Experimental emulsions were produced of the following substances: hexane, sp. gr. 0.691; chloroform, sp. gr. 1.526; carbon tetrachloride, sp. gr. 1.597; benzene, sp. gr. 0.877; oil of turpentine, sp. gr. 0.85; mineral oil, sp. gr. 0.853; cottonseed oil, sp. gr. 0.921. Gum emulsions and soap emulsions were made of all these and the conclusions, in part, were as follows: 1. The presence of a hydrated colloid is necessary for emulsification. 2. This hydration compound is most efficiently used if formed at the moment of dispersion of the internal phase—in other words, the three constituents, internal phase, emulsifier and water, in critical proportions, must all be mixed at one time in order to form a properly hydrated nucleus. 3. Slight variations from the proper procedure or from the critical proportions yield either less stable emulsions or none at all. 4. No emulsion results if the emulsifier is diluted before the dispersion of the internal phase.

EMULSUM AMYGDALÆ. U. S. (Br.)

EMULSION OF ALMOND Emuls. Amygd.

[Milk of Almond]

(ę-mŭl'sŭm ą-mŷg'dą-læ)

Mistura Amygdalæ, *Br.*; Almond Mixture; Mistura Amygdalæ, U. S. P. 1880; Emulsio Amygdalæ, s. Amygdalarum, Emulsio Simplex; Milk of Almonds; Simple Emulsion; Emulsion d'Amande, *Fr. Cod.*; Lait d'Amande, *Fr.*; Mandelemulsion, Mandelmilch, *G.*; Emulsione di mandorle dolci, *It.*; Emulsion comun, *Sp.*

• "Sweet Almond, *sixty grammes* [or 2 ounces av., 51 grains]; Acacia, in fine powder, *ten grammes* [or 154 grains]; Sugar, *thirty grammes* [or 1 ounce av., 25 grains]; Water, *a sufficient quantity*, to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Having blanched the almonds, add the acacia and sugar, and beat them, in a mortar, until they are thoroughly mixed. Then rub the mass with *nine hundred mils* [or 30 fluidounces] of water, at first very gradually added, until a uniform mixture results. Strain this into a graduated vessel, and wash the mortar and strainer with enough water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly. This preparation must not be dispensed unless it has been recently prepared." *U. S.*

"Compound Powder of Almonds, 125 *grammes;* Distilled Water, sufficient to produce 1000 *millilitres*. Triturate the Powder with a little of the Distilled Water so as to form a thin paste; gradually add the remainder of the Distilled Water; strain through fine muslin." *Br.*

These preparations are essentially the same, the gum and sugar which enter into the U. S. formula directly being ingredients of the compound powder of almonds of the British. The gum arabic in these formulas is introduced not so much for its demulcent properties as to assist in the suspension of the insoluble ingredients of the almonds. The same formula will answer for the preparation of an *emulsion of bitter almonds* from bitter almond or peach kernels. The oleaginous matter of the almonds is suspended in the water by means of their albumen, gum, and sugar, forming a milky emulsion. When the almonds themselves are employed, as in the U. S. process, care should be taken to reduce them to the consistence of a paste previously to the addition of the water, and with each successive portion of fluid a uniform mixture should be formed before another portion is added. Common water, when pure, may be properly substituted for the distilled. Great care should be taken to select the almonds perfectly free from rancidity. The emulsion is not permanent and compound powder of almonds often has a taint of rancidity when kept too long. Upon standing, the oil rises like thick cream to the surface, and

the separation is effected more quickly by heat, alcohol, and the acids, which coagulate the albumen. The preparation is closely analogous to milk in chemical relations and appearance. In warm weather it soon becomes sour.

Uses.—Emulsion of almond has a bland taste, and may be used as an agreeable, nutritive demulcent in *catarrhal* and *dysenteric affections* and irritation of the urinary passages. To be of service it must be freely employed. It is occasionally employed as an emollient lotion, and as a vehicle for less agreeable medicines, but should not be used with any considerable quantity of tinctures, acidulous salts, or other acid substances.

Dose, two to eight fluidounces (60–240 mils).

EMULSUM ASAFŒTIDÆ. U. S.

EMULSION OF ASAFETIDA Emuls. Asafœt.
[Milk of Asafœtida]

(ę-mŭl'sŭm ăs-ą-fœt'ĭ-dæ)

Asafetida Mixture; Mistura (Lac) Asafœtidæ, Mistura Asafœtida, U. S. P. 1880; Mixture (Lait) d'Asafœtida, *Fr.;* Asafœtidaemulsion, Stinkasantmilch, *G.*

* "Asafetida, in tears or selected masses, *forty grammes* [or 1 ounce av., 180 grains]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Rub the Asafetida, in a warmed mortar, with *nine hundred mils* [or 30 fluidounces] of Water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and rinse the mortar and strainer with enough Water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly." *U. S.*

The present 4 per cent. official emulsion slightly exceeds in strength the mixture of the U. S. P., 1870, which contained but 3 per cent. of asafetida. This emulsion is less stimulant than the tincture, and more prompt in its action than the pill. Its excessively disagreeable odor and taste are, however, objections, which induce a frequent preference for the last mentioned preparation. It is very often employed as an enema. From two to four fluidounces (60–120 mils) may be given by the rectum. D. Ackerman prepares a concentrated *emulsion of asafetida,* which will keep if excluded from the light, by using a mixture of three-fourths of pure water and one-fourth of diluted acetic acid as the menstruum. For cleaning mortars in which asafetida has been rubbed, he recommends solution of potassium hydroxide, followed by soap and water.

Dose, one-half to one fluidounce (15–30 mils).

EMULSUM OLEI MORRHUÆ. U. S.

EMULSION OF COD LIVER OIL Emuls. Ol. Morrh.

(ę-mŭl'sŭm ō'lę-ī mör'rhŭ-æ)

Emulsion de Huile de Foie de Morue, *Fr.;* Leberthranemulsion, *G.*

* "Cod Liver Oil, *five hundred mils* [or 16 fluidounces, 435 minims]; Acacia, in fine powder, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; Syrup, *one hundred mils* [or 3 fluidounces, 183 minims]; Methyl Salicylate, *four mils* [or 65 minims]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Thoroughly mix the acacia with the cod liver oil in a dry mortar or other suitable vessel, then add at once *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of water, and complete the emulsification by trituration or by the aid of a suitable mechanical device. When a thick, white, homogeneous mixture is obtained, add the methyl salicylate and the syrup with sufficient water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms], and mix thoroughly.

"NOTE.—The methyl salicylate may be replaced by a suitable quantity of any other flavoring." *U. S.*

This emulsion was introduced into the U. S.P. VIII for the purpose of affording a simple process for making a reasonably palatable and permanent preparation of cod liver oil. The continental method employed is best adapted for stock emulsions; to those who object to the taste of a combination of syrup and an oil with a fishy taste, the emulsion may be flavored with bruised celery seed and salt and then strained. A very palatable preparation of this type has been prepared in which the flavoring agents used were Worcestershire sauce and mustard. See *Emulsum Olei Morrhuæ cum Hypophosphitibus,* N. F. A comparison of various flavors for this emulsion was made by G. M. Beringer, Jr. (*Proc. N. J. Ph. A.,* 1914, p. 81), in which it is asserted that the best disguising flavors are those of coriander and geranium. Next came anise and cardamom, then bitter almond, clove, pimenta and vanilla. Of inferior value in this respect were peppermint, spearmint, lemon, orange and cinnamon and least valuable of all were caraway, sassafras, wintergreen and nutmeg.

Under the name of *Black Bottle,* there has long been used in New England an emulsion of cod liver oil flavored with licorice and aromatic oils, the following formula for which was contributed to the *Apothecary,* 1913, p. 24, by R. A. Newton: Powdered Acacia, 13 dr.; cod liver oil, 6½ fl. oz.; flavoring oils, 15 min.; pure extract of licorice, 5 dr.; glycerin, 2½ fl. oz.; water, to make 1 pint. Prepare an emulsion.

The flavoring oil mixture in made as follows: Oil of cassia, 1 fl. oz.; oil of lavender, ½ fl. oz.; oil of clove, 1 fl. dr.; oil of peppermint, ½ fl. dr.; Mix.

Dose, two to four fluidrachms (7.5–15 mils).

EMULSUM OLEI TEREBINTHINÆ. U. S.

EMULSION OF OIL OF TURPENTINE
Emuls. Ol. Tereb.

(ę-mŭl'sŭm ō'lę-ī tęr-ę-bĭn'thĭ-næ)

Emulsion d'Essence de Térébenthine, *Fr.;* Terpentinölemulsion, *G.*

* "Rectified Oil of Turpentine, *fifteen mils* [or 243 minims]; Expressed Oil of Almond, *five mils* [or 81 minims]; Syrup, *twenty-five mils*

[or 406 minims]; Acacia, in fine powder, *fifteen grammes* [or 231 grains]; Water, *a sufficient quantity,* to make *one hundred mils* [or 3 fluidounces, 183 minims]. Introduce the acacia into a perfectly dry bottle of sufficient capacity, add the rectified oil of turpentine and the expressed oil of almond and shake the bottle thoroughly. Then add *thirty mils* [or 1 fluidounce, 7 minims] of water and incorporate it by vigorous shaking. When the oil has been completely emulsified add first the syrup, in several portions, shaking after each addition, and then enough water, in divided portions, shaking after each addition, to make the product measure *one hundred mils* [or 3 fluidounces, 183 minims]." *U. S.*

The U. S. P. VIII introduced this emulsion with the view of providing a simple and fairly permanent preparation. Rectified oil of turpentine should be used exclusively. The process is much like the one recommended by J. Winchell Forbes, and a mortar and pestle are not needed to produce a perfect emulsion.

Dose, one-half to one fluidrachm (1.9–3.75 mils).

ERGOTA. U. S., Br.

ERGOT Ergot. [Secale Cornutum, P. I., Ergot of Rye, Spurred Rye]

(ẹr'gọ-tạ)

"The carefully dried sclerotium of *Claviceps purpurea* (Fries) Tulasne (Fam. *Hypocreaceæ*), replacing the grain of rye, *Secale cereale* Linné (Fam. *Gramineæ*), without the presence or admixture of more than 5 per cent. of seeds, fruits or other foreign matter. Before storing, dry Ergot at a temperature not exceeding 70° C. (158° F.), and preserve it, protected from light, in tightly-closed containers to which a few drops of chloroform or carbon tetrachloride are added from time to time to prevent attacks by insects." *U. S.* "Ergot is the sclerotium of Claviceps purpurea, *Tulasne,* originating in the ovary of Secale cereale, *Linn.* Ergot should be thoroughly dried and kept entire in air-tight containers; it should not be used if more than one year old." *Br.*

Secale Clavatum, Mater Secalis, Clavus Secalinus; Rye Smut, Mother of Rye, Cockspur Rye; Ergot de Seigle, *Fr. Cod.;* Ergot, Seigle Ergoté (noir), Blé Cornu, *Fr.;* Secale Cornutum, *P. G.;* Mutterkorn, Kornmutter, Rogenmutter, Zapfenkorn, Hungkorn, *G.;* Segala cornuta, Grano speronato, *It.;* Cornezuelo de centeno, *Sp.*

In all the Gramineæ, or grass family, and in some of the Cyperaceæ, the place of the grains or fruits is sometimes occupied by a morbid growth which, from its resemblance to the spur of a cock, has received the name of *ergot,* adapted from the French. This product is most frequent in the rye, *Secale cereale,* and from that grain was adopted in the first edition of the U. S. Pharmacopœia, under the name of *secale cornutum,* or *spurred rye.* In the edition of 1840 the name was changed to *ergota.* It is probable that this morbid growth has similar properties from whatever plant derived, and the fact has been proved in relation to the ergot of wheat. Tulasne found that dissimilar sclerotia collected from twelve species of grasses, produced fructification identical with that of the ergot of rye, so that it is probable that many apparently dissimilar ergots are specifically identical, their appearance being modified by the species of grass which they inhabit. It is further probable that all ergots have medicinal properties which agree in character though not in intensity. The short thick ergot which gathers upon the wild rice of Minnesota, *Zizania aquatica* L., has long been used as an abortifacient and oxytocic by the Indian women, and it is said that the wild ergot growing on various species of *Agropyrum* and *Elymus* in the Western United States, is fully equal medicinally to the official plant. M. Leperdriel, Jr., affirms that the *ergot of wheat* is destitute of the poisonous properties of that of rye, and is less liable to change. Bentley, of London, found that of two specimens, one of the ergot of rye, the other of wheat, which had been kept under similar circumstances for ten years, the former was quite destroyed, while the latter was apparently unchanged. Ergot is rarer in wheat than in rye, and in the head of the former there is generally but one and very rarely more than two of the diseased grains. It is produced usually in wheat in wet seasons, and on that side of the head most exposed to the dampness. It is shorter and much thicker than the ergot of rye, being about half an inch long and three-quarters of an inch or more in circumference, and cleft into two or three divisions. In color and odor it resembles spurred rye.

The *ergot of oats* is said to be of a black color, measuring from ten to twelve millimeters in length and three to four in thickness, and to have been used in Algeria as a substitute for rye ergot. (*L. M. R.,* March, 1888.) Warburton (*Bot. Gaz.,* 1911, p. 64) reports the occurrence of ergot on oats grown in the oat breeding nursery at Ames, Iowa. The *ergot of diss,* an Algerian reed, *Ampelodesma tenax,* has appeared in commerce to some extent. It is, when small, slightly curved, but when long (6 to 9 centimeters) it takes a spiral turn from right to left, the longitudinal furrows being present on the inner face. It is thinner, dryer, and more brittle than the ergot of rye, and has been used for the preparation of an ergotine or extract closely resembling the official one, but said to be of a more translucent red or brown color. Lallemand asserts that the ergot of diss is twice as strong as the ergot of rye, and states that it is abundant and readily collected. It is also stated to be less hygroscopic and less apt to be attacked by acari than is the official article. (*P. J.,* xvi, 684, 1886.)

Investigations of Tulasne have shown that ergot is not the diseased grain of the rye, but the *sclerotium* of a fungus, the *Claviceps purpurea* Tulasne. This fungus has three stages in its life history. The development of the *sphacelia,* or first stage, commences with that of the pistil, which serves as a soil for it. The ovary

of the rye consists of a cellular membrane made up of two coats, the outer of which has thick-walled cells; the inner being very delicate and green. The sphacelia, when it takes possession of the ovary, identifies itself with the outer layer, and in some measure replaces it, being as it were borne by the inner membrane. It rapidly increases, taking the form of the ovary, and almost obliterating its cavity. The ovule is either entirely wanting, or may be seen, on a careful examination, in an imperfect form. For some time the parasite is represented entirely by the sphacelia, which is an oblong, fungous mass, almost homogeneous, soft and tender, marked on its surface by numerous sinuous furrows, and having within many irregular cavities, which, as well as the outer coat, are uniformly covered with linear parallel cells. From the summits of these peripheric fruit bodies, internal as well as external, issue oval spores, from 0.005 to 0.007 mm. in length, which spread upon neighboring objects, and especially the glumes of the flowers they inhabit. They are a kind of reproductive cells, called conidia, which are produced by many fungi long before the perfect plant is developed. Tulasne calls them "*spermatie.*" The conidia, according to Rufmann and Maben (*P. J.*, 1908, lxxx, p. 247), are carried by a weevil from one ear of rye to another. In the early stage the sphacelia does not affect the top of the ovary, or the attached stigmas. The stamens often abort, but the filaments and anthers may sometimes be seen buried in the tissue of the sphacelia, and are altered by its action. Sometimes the ovule is not completely aborted, but it is certainly never developed into a normal grain. In all ergotized plants the pistils and stigmas, when they remain, are often covered with a mouldiness, consisting of spores and entangled filaments, which end by covering the parts with an abundant ashy or sooty powder. This is a different fungus, and was confounded by Quekett with the ergot plant. It is found as well in the non-ergotized as in the ergotized flowers, and in those of plants which do not bear ergot. At a somewhat advanced period of the development of the sphacelia, there exudes, especially from the summit, a very adhesive juice, which spreads over that structure, bearing along with it an immense number of the spores or "*spermaties.*" These leave on the surface when dry an oily appearance, and afterwards the spots, where they remain, become brownish or blackish. But this exudation does not appear until the sphacelia has ceased to constitute the whole plant.

At the base of the sphacelia is produced a compact body, violet-black without and white within, which is the ergot in a rudimentary state. With this commences the second stage in the development of the fungus. The young ergot is everywhere invested by the tissue of the sphacelia (which Tulasne calls also *spermagonia*, from its office); but, as it increases, it seems to be placed below the spermatopherous apparatus, and raises it steadily out of the floral bracts which conceal it, ending by supporting it wholly at its summit. Sometimes it carries with it the atrophied ovary, which still shows the hairs that crowned it, and some remains of the stigmas. It results that the ergot, which is technically the *sclerotium* of the fungus, remains for some time concealed in the sphacelia, so that this seems to constitute the whole plant; but, when the function belonging to this has been fulfilled, it begins to dry, and is much deformed. The ergot, on the contrary, increases in all directions, and soon appears above the glume. As it augments, the thin coating which it has received from the spermatopherous tissue, especially below, gradually becomes thinner, and seems to disappear, so that its surface, instead of being uniformly violet-black, is only here and there covered with the remains of the tissue, or with a deposit of the conidia or "*spermatie.*" Nevertheless, the sphacelia, deformed, shrunken, and worn away by rains and other causes, remains long at the top of the ergot, along with the abortive ovary, etc., and may even continue to adhere when the ergot is detached from the plant. The time required for full development of the sphacelia and the ergot or sclerotium varies. In an example under the observation of Tulasne, at least a month elapsed after the appearance of the sphacelia before the growth was completed.

Ergot has absolutely nothing in common with normal grain. The anatomical structure and all the physical characters of ergot are those of the mushrooms, or rather of a sclerotic mycelium. The parenchyma, which is whitish, dry, and brittle, consists in all its parts of irregular, globular, or polyhedric thick-walled cells, intimately united, and filled with a limpid oil, but feebly colored by iodine. The superficial utricles, which alone are colored, have an outer wall thicker than the inner, and the color of these is what gives its characteristic hue to ergot. Not the least trace of starch is to be detected. If ergot is planted in a suitable soil, evidences of germination are seen in about three months. Little globular prominences appear on its surface, which gradually enlarge, and raise themselves upon cylindrical stems, and finally become perfect pilei or fruiting fungi, producing elongated, rod-like spores in flask-shaped cavities which open by a little pore. These little fungi belong to the genus *Sphæria*. As they increase, the interior of the ergot becomes exhausted, by contributing to their growth. Falling to the ground, in its natural course, the ergot in the soil germinates, and produces pilei, the spores of which, carried up with the juices of rye, become lodged in the ovary, where they begin the course of life and progress which has been described. Different grains are probably infested with different species of Claviceps, but there is no reason to think that any other species is concerned in the product of any official variety of ergot. (*Annales des Sciences Naturelles*, 3e sér., xx, 5, 1853.) The ergot usually projects out of the glume or husk beyond the ordinary outline of the spike or ear. In some spikes the

place of the seeds is wholly occupied by the ergot in others only two or three spurs are observed. It is said to be much more energetic when collected before than after harvest. Rye has generally been thought to be most subject to the disease in poor and wet soils, and in rainy seasons, and intense heat succeeding continued rains has been said to favor its development, especially if these circumstances occur at the time the flower is forming. It is now, however, asserted that moisture has little or nothing to do with its production. It should not be collected until some days after it has begun to form, as, according to Bonjean, if gathered on the first day it does not possess the poisonous properties which it exhibits when taken on the sixth day. (See *P. J.*, Jan., 1842.) Ergot enters commerce chiefly from Russia, Germany, and Spain. Of the three varieties the Spanish ergot is considered the best, yielding usually from 13 to 15, sometimes as high as 18, per cent. of extractive. It is somewhat darker colored, rather shorter, and more uniform than is the German ergot. An ergot of excellent quality has been sent from the Canary Islands to England. The average annual import of ergot into the United States is about 120,000 pounds. The exports from Russia in 1906 were 430,000 pounds.

Properties.—The official description is as follows: "Cylindraceous, obscurely three-angled, tapering towards both ends, obtuse, somewhat curved, from 1 to 4.5 cm. in length and from 3 to 5 mm. in thickness; externally purplish-black, or brownish-black, longitudinally furrowed; fracture short, pinkish or reddish-white, sometimes grayish-white; odor peculiar, disagreeable, free from mustiness; taste oily and disagreeable. Pour hot water on bruised Ergot; no ammoniacal or rancid odor develops. The powder is grayish-brown, consisting chiefly of whitish fragments composed of false parenchyma of compacted hyphæ and a few purplish colored fragments of the outer layer of the sclerotium; mounts made in hydrated chloral T.S. or in sulphuric acid show the separation of numerous globules of a fixed oil, and many of the fragments are colored yellowish, reddish or rose-purple. Shake 1 Gm. of the powdered drug with a mixture of 20 mils of water and one drop of hydrochloric acid, filter the mixture, make 4 mils of the filtrate alkaline with ammonia water and shake out with 10 mils of ether. Underlay 5 mils of this ethereal solution with 2 mils of sulphuric acid; a blue ring is formed at the zone of contact of the two liquids. Ergot yields not more than 5 per cent. of ash." *U. S.*

"Subcylindrical or somewhat triangular, tapering towards the ends, generally curved; from one and a half to four centimetres long; longitudinally furrowed on each side, but more especially on that which is concave; often irregularly cracked; very dark violet-black externally, whitish or pinkish-white within; fracture short. Odor characteristic and disagreeable, especially when triturated with *solution of sodium hydroxide;* taste disagreeable." *Br.*

The aqueous infusion or decoction is claret-colored, and has an acid reaction. It is precipitated by lead acetate and subacetate, silver nitrate, and tincture of galls, but affords with iodine no evidence of the presence of starch. Long boiling impairs the virtues of ergot. The U. S. P. VIII and the British Pharm., 1914, state that ergot should not be kept for more than a year, but the U. S. P. IX revision has omitted this statement. While there is not sufficient data to allow of positive conclusions, Wood and Hofer (*A. In. M.*, 1910, vi, 388) found that in a sample carefully dried and sealed the activity was not perceptibly diminished after six months, and Eberhardt and Eldred (*J. A. Ph. A.*, 1914, iii, 38) quote Moss as having shown that freed from its oil ergot will retain its virtues unimpaired for two and even five years. (For discussion of the deterioration of the *Fluidextract of Ergot,* see p. 490). The germinating test has been utilized in determining a good quality of ergot and Zimmermann (*Ztschr. f. Pflanzenkrankheiten,* 1907, p. 129) concludes that the sclerotium of *Claviceps purpurea* is capable of germinating even after keeping for two years. Ergot sometimes contains small stones and cereal grains, implying that it has not been carefully garbled. Many samples are "wormy," some really being alive with insects. Old ergot is sometimes brightened by the use of a fixed oil; the revisers of Vienna Pharmacies (*Pharm. Prax.*, 1905, p. 38) reported finding one sample of powdered ergot which contained flour as an adulterant.

Ergot, when perfectly dry and kept in well-stoppered bottles, will retain its virtues for a considerable time, but exposed to air and moisture it speedily undergoes chemical change and deteriorates. It is, moreover, apt to be attacked by a minute worm, which consumes the interior of the grain, leaving the exterior shell and an excrementitious powder. This insect is sometimes found in the ergot before removal from the plant. In the state of powder the medicine more readily deteriorates, but Dragendorff believes that the decay is due to oxidization of the fatty principles of the ergot, and can be prevented by depriving the ergot of its oil before powdering. (*A. P. S.*, XXV.) Camphor and powdered benzoin are said to prevent injury from worms. Aymoiner immerses fresh ergot in an ethereal solution of tolu, dries it, and preserves in tightly closed bottles.

Ergot has been analyzed by Vauquelin, Winckler, Wiggers, Wright, Legrip, Wenzell, Tanret, Dragendorff, and several others. Wright supposed the virtues of ergot to reside in the fixed oil, which he therefore recommended as a substitute for the medicine. The *oil of ergot,* when obtained from grains recently collected, is, according to Wright, often quite free from color, but as usually prepared it is reddish-brown. It has a disagreeable, somewhat acrid taste, is lighter than water, and is soluble in alcohol and alkaline solutions. It is prepared by forming an ethereal tincture of ergot by the process of

percolation, and evaporating the ether with a gentle heat. It may be more cheaply prepared by substituting petroleum benzin for ether. Experience has shown that, though the oil thus prepared with ether may have produced effects analogous to those of ergot, they were to be ascribed rather to some principle extracted along with the oil by the menstruum than to the oil itself, for, when procured by expression, this has been found to be inactive. According to T. R. Baker, the oil has a taste and odor similar to those of castor oil, with which it also agrees in ultimate composition, and yields analogous results in saponification. T. C. Herrmann investigated specially the chemical constitution of the oil of ergot. As obtained by means of ether, it was brownish-yellow, of an aromatic odor and acrid taste, viscid, of the sp. gr. 0.9249, and without the drying property. It consists of 22.703 per cent. of palmitic acid, 69.205 of oleic acid, and 8.091 of glycerin. (*N. R.*, 1872, p. 238; from *Buchner's Repertorium*, 1871, p. 283.) The *sugar of ergot* was found by Mitscherlich to be *mycose*, $C_{12}H_{22}O_{11}$. According to Wenzell (*A. J. P.*, May, 1864), ergot of rye contains two peculiar alkaloids, which he designated *ecboline* and *ergotine*, and claimed to be the active principles of the drug. The two bases of ergot are, according to Wenzell, combined with *ergotic acid*, the existence of which has been further admitted by Ganser. It is said to be a volatile body yielding crystallizable salts.

A crystallizable, colorless alkaloid, *ergotinine*, $C_{35}H_{40}N_4O_6$, which is probably identical with Wenzell's ergotine, was isolated (1877–1878) by Tanret. He obtained it to the amount of 0.04 per cent., some amorphous ergotine, moreover, being present. The solutions of ergotinine turn greenish and red very soon; they are fluorescent. Sulphuric acid imparts to it a red, violet, and finally blue hue.

Tanret also observed in ergot of rye a volatile *camphoraceous* substance.

Voswinkel obtained from ergot a brown amorphous substance, which he proved by hydrolysis to yield *mannose*. The body is a semi-cellulose, and the name *mannan* has been given to it. He states that Dragendorff's *sclerotic acid* and *scleromucin* are identical with mannan. (*Ph. Centralh.*, 1891, p. 531.)

Kobert (*Ph. Centralh.*, 1884, p. 607; All, *Das Mutterkorns*, Leipzig, 1884) found three physiologically active principles: 1st, *ergotic acid*, which he considers the principal constituent of the sclerotic acid of Dragendorff and Podwissotzky, and which is isolated by precipitation with ammoniacal lead subacetate; 2d, *sphacelic acid*, which can be isolated by taking advantage of the insolubility of the free acid in water and its solubility in alcohol; 3d, the alkaloid *cornutine*, which is not identical with the crystalline or with the amorphous ergotinine of Tanret; it is readily soluble in alcohol, and is obtained from an alkaline aqueous solution by agitation with ether. This alkaloid is said to be very poisonous. Kobert's conclusions were questioned by Tanret (*P. J.*, 1885, p. 889), but the former reaffirms his statements and believes that ergotinine is worthless, and that the activity of fresh ergot is due to sphacelic acid and cornutine as above described (*A. Pharm.*, 1886, p. 597). At present (1917) the activity of ergot seems to be due to the presence of (1) a characteristic alkaloid discovered almost simultaneously by Barger and Walpole, and by Kraft (*Pharm.*, 1906), the former calling it *ergotoxine* and the latter *hydro-ergotinine* to show its relation to the *ergotinine* of Tanret which is inert; (2) to certain amines which are common to various putrefying materials. Of these amines there have been so far separated *para-phenyl-hydroxylamine* (also known as *tyramine* or *uteramine*), and *beta-iminazolethylamine* (*histamine, ergamine, imidazol*). Besides these Ewins (*Biochem. J.*, 1914, viii, p. 44) has shown the occurrence in certain specimens of ergot of *acetyl-choline* which is a powerful circulatory depressant, and more or less antagonistic to the other principles of ergot. Cornutine of Kobert apparently does not occur in ergot but is an artefact. (The cornutine of Keller is a very different substance and appears to represent all of the alkaloidal bodies present in the crude drug.) *Sphacelotoxin*, described by Jacoby, is a substance having acid properties contaminated with ergotoxin; Wood and Hofer believe that the acid and the alkaloid are in chemical combination. Barger and Ewins (*Tr. Chem. Soc.*, 1910, xcvii, p. 284) have shown that ergotoxine has the formula $C_{35}H_{41}O_6N_5$. Tanret's ergotinine has $C_{35}H_{39}O_5N_5$, so that it is the anhydride of ergotoxin. Ergotoxine may be changed into ergotonine by boiling with methyl alcohol or acetic anhydride.

Carr and Dale (*W. Br. Ph. Conf.*, 1913, 505) presented a comprehensive and critical review of the preparations of ergot with especial reference, of course, to the B. P., but containing much that is of value in connection with our own official preparations. They state that as *ergotoxine* is the recognized active principle of ergot the value of ergot and its preparations should be judged by the content of that principle. They also recognize the supplementary value of the amines, such as *ergamine*, and state that, given equal ergotoxine values, the sample which is higher in amines will be therapeutically superior. They commend the U. S. P. VIII fluidextract as being a preparation of great value.

Assay.—The great variation in the potency of different samples of ergot, as well as its practical importance, has led to a number of attempts to develop means of determining the quality of the drug. These efforts have included both the chemical and the biological assay.

The earliest systematic use of the biological reaction for determining the quality of ergot were the experiments of Grünfeld in 1895. His method was based upon the quantity of the sample which was necessary to cause gangrene in the combs and wattles of roosters, and is commonly spoken of as the *cock's comb method.*

This test was later utilized by Houghton (*T. G.*, 1898) on a commercial scale.

The criterion of the cock's comb method is the dose of a sample of ergot which is required to cause a bluing of the comb. It is important that the same breed of chickens be used throughout any series of experiments; white Leghorns are generally preferred. The method is carried out as follows: A rooster is weighed, and then a dose of the fluidextract to be tested, equivalent to about 1 mil (16 minims) per kilogramme, is injected into the muscle of the breast. An hour later the bird is examined. If the specimen has been an active one, there will be a bluish or cyanotic appearance around the edge of the comb. The extent and degree of this discoloration is noted. The same rooster may be used over and over again, and the experimenter soon learns the degree of bluing which is the characteristic reaction of that individual chicken for a standard dose of the active drug. If, however, no bluing occurs, the drug is below the standard.

The idea of using the elevation of blood pressure for the assay of ergot seems to have been first suggested by Dixon (*P. J.*, 1905), and was elaborated by Wood and Hofer. (*A. In. M.*, 1910, vi, 388.) The method as employed by the latter is as follows: A dog is anesthetized with morphine and ether, and the carotid artery connected with a mercurial manometer. The normal blood pressure is observed, and then a dose of the sample equivalent to 0.15 Gm. of ergot for each kilo of body weight is injected intravenously, and the blood pressure noted (1) at its highest point after the injection, (2) five minutes after, and (3) ten minutes after the injection, the average elevation above the norm of these three observations represents the physiological activity of the specimen. In order to obviate peculiar susceptibility in individual dogs, it is necessary that experiments be made upon three animals with each sample. Edmunds and Hale modified the method by previously administering atropine for the purpose of avoiding the stimulant action upon the vagus, but their results were less consistent than those who have worked on the normal animal. The two objections which have been urged against this method are, in the first place, the assertion that because the drug is used chiefly as a uterine stimulant, a blood pressure test does not give satisfactory criterion of the therapeutic activity of the drug, and secondly, the possibility of a marked abnormality in the reaction of one of the experimental animals creating a false idea of the activity of the drug. An attempt has been made to obviate this last objection by comparing the effects of a standard specimen upon the same animal.

The most important objection which has been urged against this measure is that since the drug is used chiefly as a uterine stimulant the blood pressure test is not a satisfactory criterion of its therapeutic activity. This objection, however, must not be given too great stress because, in the first place, since ergot is widely used for its vasomotor effect it is important to know its action on the circulation, and in the second place, Stewart and Pittinger (*Trans. of the Amer. Therap. Soc.*, 1914) have shown that there is a close parallelism between the degree of action of various samples of ergot upon the blood pressure and upon the uterus.

Two methods in which the uterine muscle is used as an indicator of ergot have been suggested, that of Kehrer (*A. E. P. P.*, 1908, lviii) in which the uterus is removed from the body and either strips of the isolated muscle or the whole organ are employed, and that of Edmunds in which the uterus *in situ* furnishes the test reaction.

In the first of these the uterus of the guinea-pig is cut out of the body and placed in Locke's solution (see *Liquor Sodii Chloridi Physiologicus*) which is kept at the body temperature and through which oxygen is constantly bubbling. One end of the uterus is fixed and the other attached to a muscle lever which records on a slowly moving drum. The lever is weighted sufficiently to reduce the normal contractions to small size. After waiting a sufficient length of time for the disturbance of function caused by the operation to have subsided, various strengths of a standard solution are added to the Locke fluid in which the uterus is immersed until the amount which is required to produce a barely submaximal contraction has been determined: between the tests with each strength of solution the uterus is washed with normal Locke fluid. After determination of the strength of the standard preparation for the individual uterus being employed, the solution to be tested is added in corresponding strength and then in higher or lower concentration until the amount is found which produces the same degree of contraction as the standard solution.

As a comparison either a standard solution of ergot or of hypophysis may be used. Pittinger and Vanderkleed (*J. A. Ph. A.*, 1914, iii, p. 925) have modified this method by adding weights until the uterus is barely able to move the lever and testing the strength of the muscle against this added resistance.

The method employed by Edmunds (*Hygienic Lab. Bul.*, No. 76, July, 1911) is most satisfactorily performed upon cats. The anesthetized animal, which is kept alive by artificial respiration throughout the experiment, is immersed in a bath of physiological salt solution at a temperature of 39° C. (102.2° F.), the abdomen is then opened by a medium incision, the bladder and intestines drawn aside; one horn of the exposed uterus freed by tearing away the peritoneal attachments and two fine silk threads passed through this horn at a distance of about two centimeters apart. These threads are then connected to a light muscle lever. To obtain the proper degree of tension weights may be added to the muscle lever. The ergot to be tested is then injected intravenously alternating with a standard solution. As in this method there is no definite end reaction it is often difficult to

judge of the relative potency of the two preparations. Edmunds and Hale themselves say of it: "It is not an unusual experience to carry on such an experiment for two or three hours and . . . . to know very little more about the relative strengths of the two specimens at the end than at the beginning of the experiment."

There are several practical objections to all the uterine methods of assay. In the first place, they require a greater degree of technical skill in carrying out than either the blood pressure or cock's comb methods; in the second place, there is no definite end-point of the reaction so that it is difficult to make quantitative comparisons; and in the third place, the uteri of different species of animals do not respond in the same way to the drug, and even in the same species the effect may vary. Thus Dale finds that isolated strips of uterine muscle from the guinea-pig respond to ergotoxine but similar strips from the cat do not, although the intact uterus from the latter animal is excited by this alkaloid; tyramine causes contraction of the uterus in the pregnant and relaxation in the virgin cat.

There has been much discussion as to which method is the most useful for standardizing ergot. For commercial purposes at least the choice lies between the cock's comb and the blood pressure method. The former has the great advantage of its simplicity, but it has the disadvantage of the absence of a sharp end reaction, for the change in the color of the comb may vary anywhere from an almost imperceptible darkening of the tip to a deep cyanotic color of the whole appendage—and hence leaves a wider range for possible personal error. As the different principles of ergot produce different physiological effects, it is evident that the two tests may give very different results for the same specimen of ergot; thus ergotoxine causes both bluing of the comb and rise in blood pressure; while tyramine causes rise in blood pressure but no bluing, while histamine causes no rise in blood pressure but, according to Crawford and Crawford (*J. A. M. A.*, 1913, lxi), it does cause bluing of the comb. For reasons pointed out by Crawford and Crawford, it is improbable that the fluidextract of ergot, prepared according to the U. S. P. will contain any considerable proportion of histamine, and it would seem, therefore, that a blood pressure method would furnish more accurate information concerning the American fluidextract than the test upon the rooster. But it must be remembered that the proper performance of the blood pressure test requires more technical skill than that upon the rooster, and in the hands of the unpractised it is probable that the cock's comb method would yield more favorable results.

The reader who is interested in this subject may find extensive references to the literature in the paper of Wood and Hofer (*A. In. M.*, 1910, iv, p. 388) and of Edmunds and Hale (*U. S. Hygienic Laboratory Bull.*, No. 76, 1911).

Pearson (*J. A. Ph. A.*, 1913, ii, p. 1453) reports upon the tests of the Activity of Ergot by the Blood Pressure Method. One of the first evidences of deterioration of preparations of ergot is the loss of the power to sustain the blood pressure; a good preparation will keep the blood pressure up for about two hours. Heated on a water bath for thirty minutes the fluidextract of ergot loses almost completely its power of raising the blood pressure. Evaporating at room temperature by a current of air does not destroy its activity. Extract of ergot (U. S. P.) had practically no effect on blood pressure. Bonjean's ergotin produced no rise and usually a decided fall in pressure. A powdered extract (method of manufacture not given) produced a temporary rise but the increased pressure was not sustained.

Uses.—Ergot is a stimulant to all forms of involuntary muscle fibers, the most important being the heart, the arteries, and the uterus. When a dose of ergot is injected intravenously there occurs a rise in the blood pressure, sometimes preceded by a transient fall, and accompanied with a reduction in the rate of the pulse. The elevation of the pressure is due in part to a contraction of the blood vessels, the result of a direct stimulant action upon their muscular coats, but also in part to a stimulating effect upon the cardiac muscle. The effect of a small dose of ergot upon the uterus is to increase both the vigor of its contraction, and its muscular tone. If the dose is larger, the increase in muscle tone becomes relatively more and more pronounced, until eventually the organ may be thrown into a permanent spasmodic contraction. Other evidences of the stimulating effect of ergot upon unstriped muscle are seen in increased intestinal peristalsis, contraction of the pupil, and of the bladder.

On the continent of Europe ergot has long been empirically employed by midwives for promoting contraction of the uterus, and its German name "Mutterkorn" implies the popular acceptance of its peculiar powers, but it was first introduced to the regular medical profession as the result of the writings of Stearns (*N. Y. Medical Repository*, 1807.) While a remedy of undoubted utility in properly selected cases of *labor*, its injudicious use may do much harm, and even prove fatal to either the mother or the child. When used freely, ergot is liable to transform the normal intermittent contractions of the parturient uterus into one violent spasm. If this spasmodic contraction occurs too early in the course of the birth process it may lead to asphyxiation of the child, to wide lacerations of the birth canal, or even to rupture of the uterus. In the third stage of labor, however, no such accidents can occur, and many obstetricians recommend the routine use of ergot at this time, as a prophylactic against *post partum hemorrhage*. Ergot is also used as a stimulant to the non-pregnant uterus to check bleeding in *menorrhagias* and *metrorrhagias*.

As a circulatory stimulant, ergot deserves more popularity than it has received. Although certain authors have found it a serviceable remedy in acute circulatory failure, such as *surgical shock,* the slowness of its action interferes with its utility in this condition, and its most important field of usefulness is in chronic vasomotor relaxations. Thus, it is useful in cerebral or *spinal congestion,* in *colliquative sweats,* in relaxing *diarrhea,* and similar conditions in which there are local passive congestions. Because of its success in hemorrhage from the uterus, ergot has been widely employed in various other internal *hemorrhages,* but its value under these circumstances is doubtful. Probably because of the effects of ergot on the circulation it is a very valuable remedy in the treatment of *delirium tremens.* (See Ranson and Scott, *A. J. M. S.,* 1911, cxli, p. 673.) Osborne (*N. Y. M. R.,* July 14, 1906) says that it has a powerful sedative effect upon the central nervous system and is useful in certain types of *asthma,* in *Graves's disease, hysteria,* and especially for the nervousness in the withdrawal of morphine.

Under the name of ergotin, usually with the name of the maker attached, a number of more or less purified extracts of ergot are upon the market. The doses of these range from one to ten grains according to their purity. *Bonjean's Ergotin* is made by exhausting ergot with water, evaporating to the consistency of syrup, precipitating the albumen, gum, etc., with alcohol, decanting the clear liquid and evaporating to the consistency of the soft extract. It is to be remembered in this connection that no aqueous extract of ergot can thoroughly represent the crude drug. *Ergotoxine* is marketed in the form of a crystalline phosphate, the dose of which is from one one-hundredth to one-fiftieth of a grain (0.0006–0.0013 Gm.). The hydrochloride of para-hydroxyphenylethylamine is sold under the trade name of *tyramine.* Its dose is from one-twelfth to one-half of a grain (0.005–0.032 Gm.).

The most widely used unofficial preparations of ergot are as follows:

Ergotin Bonjean (see *Extractum Ergotæ Aquosum,* Part III).—*Dose,* three to eight grains (0.2–0.5 Gm.).

Ergotin Wernich Merck.—Purified, dried, dialyzed aqueous extract of ergot. *Dose,* twenty grains (1.3 Gm.).

Ergotin Wiggers.—*Dose,* ten to fifteen minims (0.6–0.9 mil).

Ergotole.—*Dose,* five to twenty minims (0.3–1.3 mils).

Ernutin.—*Dose,* five to ten minims (0.3–0.6 mil).

Ergone.—*Dose,* fifteen to thirty minims (0.9–1.8 mils).

Cornutol (*Liquid Extractum Ergotæ*).—*Dose,* ten to thirty minims (0.6–1.8 mils).

Clavin.—*Dose,* one-third of a grain (0.02 Gm.).

Toxicology.—Ergot can scarcely be considered as a poison, since an ounce of the fluidextract rarely produces, except in the pregnant, any obvious symptoms unless it be nausea. Large doses are liable, it is true, to produce abortion in pregnant women, but even this result is uncertain. We know of but one instance of fatal poisoning by it, unless the death was produced by the abortion. The symptoms of the recorded cases of poisoning have been paleness, and, as most characteristic, an especial coldness of the surface, partial paralysis with numbness and tingling in the limbs, feebleness of the pulse, restlessness, and finally stupor or delirium.

On the other hand, the long continued and free use of ergot is highly dangerous, even when no immediate effects are perceptible. Fatal epidemics in different parts of the continent of Europe, particularly in certain provinces of France, have long been ascribed to the use of bread made from rye contaminated with this fungus. Dry gangrene, and disorder of the nervous system attended with convulsions, are the forms of disease which have followed the use of this unwholesome food. It is true that ergot has been denied to be the cause, but accurate investigations made by competent men upon the spot where the epidemics have prevailed, together with experiments upon inferior animals, leave no room for reasonable doubt that at least the gangrenous affection alluded to has resulted from it.

Dose, of ergot, fifteen to sixty grains (1–3.9 Gm.).

ERIODICTYON. U. S.

ERIODICTYON Eriodict. [Yerba Santa]

(ĕr-ī-o-dĭc'tŷ-ŏn)

"The dried leaves of *Eriodictyon californicum* (Hooker and Arnott) Greene (Fam. *Hydrophyllaceæ*), without the presence or admixture of more than 5 per cent. of stems or other foreign matter." *U. S.*

Mountain Balm, Consumptive's Weed, Bear's Weed, Gum Bush.

Eriodictyon californicum is a low evergreen shrub growing abundantly upon dry hills in California. It is glabrous, resinous, having short petiolate, long lanceolate leaves, irregularly more or less serrate, sometimes entire, whitened beneath, between the reticulations, by a minute and close tomentum, above glabrous. The corolla is tubular funnel-form; the calyx being sparsely hirsute. The leaf structure has been studied by F. W. Ritter. (See *A. J. P.,* 1895, 565.)

E. tomentosum, which grows often along with *E. californicum,* especially in the southern part of California, is readily distinguished by its dense coat of short villous hairs, whitish or rusty-colored with age. It is also a larger shrub than *E. californicum,* has its corolla somewhat salver-

form, and its leaves oblong or oval, and obtuse.

Properties.—The leaves of eriodictyon are characterized by the U. S. Pharmacopœia as "Usually in fragments; when entire, laminæ lanceolate, from 5 to 15 cm. in length, and from 1 to 3 cm. in breadth; summits acute; bases slightly tapering into short petioles; margins irregularly serrate or crenate-dentate; upper surfaces yellowish-brown, covered with a more or less glistening resin; under surfaces grayish or yellowish-white, conspicuously reticulate with greenish-yellow veins; minutely tomentose between the reticulations; thick, brittle; odor aromatic; taste balsamic, bitter, becoming sweetish. Under the microscope, transverse sections of the laminæ of Eriodictyon show upon the upper surface large epidermal cells, the outer walls being very uneven, owing to indentations which appear as striations in surface view; glandular hairs numerous, with short 1-celled stalks and 6- to 8-celled glandular heads; palisade cells very narrow, from 2 to 6 rows deep, containing numerous chloroplastids; cells of dorsal-pneumatic tissue (loose mesophyll) very few; fibro-vascular tissues not strongly developed except in the midrib and more prominent veins; numerous 1-celled, much twisted, thick-walled, non-glandular hairs occurring on the lower surface between the veins. Under the microscope, sections of the stems of Eriodictyon show the epidermis usually replaced by strongly lignified cork; cortex of from 10 to 20 rows of more or less rounded cells; bast-fibers deep-seated with thick, more or less strongly lignified walls and occurring in small groups forming a more or less interrupted circle; sieve tissues in a narrow zone; wood-wedges consisting of tracheæ with spiral thickenings, simple or bordered pores and numerous strongly lignified wood-fibers, separated by medullary rays 1-cell in width; pith very large, the walls of the cells being strongly lignified and with numerous simple pores." *U. S.*

Tunmann (*Ph. Centralh.*, 1908, p. 159) describes and illustrates the pharmacognostic and microscopic characteristics of *Eriodictyon californicum*, and discusses the morphological importance of the oil glands of eriodictyon. H. S. Wellcome (*The Pharmacist*, 1876, p. 33) found the drug to contain two aromatic resins, while an aqueous infusion of leaves which had been exhausted by alcohol yielded an intensely bitter extract. According to the analysis of Chas. Mohr (*A. J. P.*, 1879, 549), it contains tannic acid and 8 per cent. of an acrid, bitter, resin, upon which its activity is believed to depend, also a minute quantity of volatile oil. R. Rother describes (*A. J. P.*, 1887, p. 225) an acid resin which forms with bases quite soluble salts. The acid resin was obtained at the conclusion of the spontaneous volatilization of the several solvents as a green-yellow transparent mass. Thal (*Ph. Z. R.*, 1883, p. 209) affirmed the presence of *ericolin*, $C_{34}H_{56}O_{21}$. Power and Tutin deny that ericolin is present but find besides volatile oil and resin, *triacontane*, $C_{30}H_{62}$, *penta triacontane*, $C_{35}H_{72}$, *eriodictyol*, $C_{15}H_{12}O_6$, *homoeriodictyol*, $C_{16}H_{14}O_6$, and a phenol, $C_{16}H_{42}O_6$.

Uses.—Eriodictyon has long been used in California as a bitter tonic, and also as a stimulant balsamic expectorant. There is considerable testimony to its usefulness in *asthma, chronic bronchitis*, and allied conditions; also in chronic inflammation of the genito-urinary tract. Attention has been called by Kier to its remarkable power of disguising the taste of quinine, and Meyer (*Ph. Ztg.*, 1905) found that it will also mitigate the unpleasantness of hydrastis or aspidium. It is best exhibited in the form of the official fluidextract, the dose of which is one-half to one fluidrachm (1.8–3.75 mils); a solid extract has been made, which may be given in doses of from five to fifteen grains (0.32–1.0 Gm.). In cases of asthma, eriodictyon is often used by smoking. The aromatic syrup is well adapted as a vehicle for quinine.

Dose, fifteen to sixty grains (1.0–3.9 Gm.).

EUCALYPTOL. U. S.

EUCALYPTOL [Cineol]

(eū-ca-lyp'tŏl)

"An organic compound [$C_{10}H_{18}O = 154.14$] obtained from the volatile oil of *Eucalyptus Globulus* Labillardière (Fam. *Myrtaceæ*) and from other sources. Preserve it in well-closed containers, in a cool place, protected from light." *U. S.*

Eucalyptol, *Fr. Cod.*; Cinéol, Terpane, Cajeputol, *Fr.*; Terpan, *G.*; Eucaliptol, *Sp.*

In the distillation of eucalyptus leaves, the portion which comes over between 170° C. (338° F.) and 178° C. (352.4° F.) is set aside as crude eucalyptol. To obtain it pure a redistillation from potassium hydroxide or calcium chloride is necessary. It is very liquid, nearly colorless, with a strong, aromatic, camphoraceous odor, is slightly soluble in water, but very freely soluble in alcohol. Nitric acid produces with it a crystallizable acid; by the action of phosphoric anhydride (*J. P. C.*, 4e sér., xii, 204) it is converted into *eucalyptene*, $C_{10}H_{16}$, a substance allied to cymene, and *eucalyptolen*.

C. Jahns (*A. J. P.*, 1885, p. 237) gave the formula $C_{10}H_{18}O$ to eucalyptol, and showed it to be identical with cajuputol, or, as it is now generally known, *cineol*. Wallach (*Ann. Ch. Ph.*, 248, pp. 278 to 283) showed that the oil from *E. Globulus* contained cineol (eucalyptol) and *dextro-pinene*, while that from *E. amygdalina* Labill., contained cineol and *lævo-phellandrene*. (For the nearer study of oil of eucalyptus and for consideration of other eucalyptol bearing oils, see under *Oleum Eucalypti.*)

The U. S. P. describes it as "a colorless liquid, having a characteristic, aromatic and distinctly camphoraceous odor, and a pungent, spicy taste;

it produces a cooling sensation in the mouth. Eucalyptol is very slightly soluble in water, miscible with alcohol, chloroform, ether, glacial acetic acid, or fixed or volatile oils. Specific gravity: 0.921 to 0.923 at 25° C. (77° F.). It boils between 174° and 177° C. (345.2° and 350.6° F.). Congealing point: not below 0° C. (32° F.). Eucalyptol is optically inactive (distinction from *oil of eucalyptus and many other volatile oils*). Place 1 mil of Eucalyptol in a freezing mixture and gradually add to it an equal volume of phosphoric acid; a solid, white, crystalline mass of cineol-phosphoric acid results, and if warm water is then added the Eucalyptol separates. Shake 5 mils of Eucalyptol with 5 mils of sodium hydroxide T.S.; the volume of the Eucalyptol is not diminished (*saponifiable oils*). Its alcoholic solution (1 in 10) is neutral to moistened litmus paper, and, on adding a drop of ferric chloride T.S. to 5 mils of this solution, no brown or violet color is produced (*phenols*)." *U. S.*

Uses.—Eucalyptol has to a considerable extent replaced the oil of eucalyptus especially as a stimulant expectorant in *chronic bronchitis* and *bronchorrhea*, etc. Berliner (*B. K. W.*, 1913, p. 1703) injected hypodermically an oily solution of menthol and eucalyptol in the treatment of *tuberculosis of the lungs* with asserted great benefit. Eucalyptol is also widely employed as a vermifuge. Locally it is a popular addition to various washes and sprays to be used in the nose and throat, because of its antiseptic action. Brownscomb (*Chemist and Druggist*, 1910), however, asserts that eucalyptol is a less powerful antiseptic than the other ingredients of the oil of eucalyptus.

Dose, five to ten minims (0.3–0.6 mil), four to six times a day.

EUCALYPTUS. U. S.

EUCALYPTUS Eucalypt. [Blue Gum Leaves]

(eū-ca-lȳp'tŭs)

"The dried leaves of *Eucalyptus Globulus* Labillardière (Fam. *Myrtaceæ*), collected from the older parts of the tree, without the presence or admixture of more than 3 per cent. of the stems, fruits or other foreign matter." *U. S.*

Blue Gum-tree Leaves, Australian Fever-tree Leaves, Eucalyptus Leaves; Eucalyptus, *Fr. Cod.;* Feuilles d'Eucalyptus, *Fr.;* Eucalyptusblätter, *G.;* Eucalitto, *It.;* Eucalipto (Hoja de), *Sp.*

The genus *Eucalyptus* was named by L'Heritier in 1788, from the two Greek words meaning "I cover well," "in allusion to the operculum or lid which covers the calyx until the stamens are fully formed." The plants, which are known as *Gum trees, Woolly butts, Iron barks*, etc., by the natives of Australia and Tasmania, are evergreen and vary from shrubs to trees of enormous height, some of them probably being the highest trees known. Kerner gives the height as 140 to 152 meters. They form, it is stated, about three-fourths of the whole vegetation of those countries. At least one hundred and forty species have been described. The leaves frequently vary in shape and in position on both young and mature trees; they are fixed vertically, and not horizontally as the leaves of our trees, the petiole being twisted. The leaves furthermore contain large oil-secreting reservoirs. The flowers are arranged in cymes or axillary umbels and are devoid of petals; the usually whitish stamens are inflexed in the bud and expand when the operculum is removed, giving the name as already stated to the genus. The fruit is a 3- to 6-celled truncated capsule, or pyxis. The seeds are small and very numerous, the sterile ones predominating; this is no doubt one reason why there has been so much difficulty in producing seedlings.

Most of the species do not require excessive heat for their perfecting, and some of them are able to resist moderate frosts. Over forty species are being grown successfully in the United States, and in the neighborhood of Los Angeles and other points in California a pure oil is said to be commercially produced. On account of the rapidity of their growth and the hardness and indestructibility of their timber, many of the species are very valuable for economic purposes. A number of the species are said to be cultivated in the Southwest as a source of honey. (See *Bulletin No. 35 of the U. S. Bureau of Forestry.*)

With a genus of so many species and numerous varieties it was to be expected that there would be considerable confusion in regard to the accurate determination of its members. Tate and Luehman give prominence to the fruit for purposes of classification. Maiden, however, says that all of its characters display a puzzling amount of variation, and concludes that for herbarium work the best characters are afforded by the anthers and fruits; whereas the scientific forester will be largely guided by the nature of the bark and timber. Baker and Smith, in addition to morphological characters, base their deductions on the chemical properties and physical characters of oils, dyes, kinos, etc. See Bentham, *Flora Australiensis;* Baron F. von Mueller's *Eucalyptographia*, 1879 to 1884. Baker and Smith (*A Research on the Eucalypts*, Sydney, 1902), arrange the species in seven different groups, according to the chemical characteristics of the oils which they produce. It is stated that the leaves of the *E. rebaudianum*, of Paraguay, are used in that country in place of sugar, which they exceed in sweetening power.

Eucalyptus globulus is one of the largest known trees, attaining sometimes a height of 300 or even 350 feet, with a smooth, ash-colored

bark. The leaves attain a foot in length, and vary, according to age, from a glaucous white to a bluish-green color. The flowers are large, pinkish-white, axillary, occurring singly, or in clusters. Although its wood is very resinous, hard, and durable, the tree is remarkable for the rapidity of its growth, reaching, under favorable circumstances, fifty feet of height in five or six years. It flourishes best in valleys having a rich, moist soil, and has very largely been naturalized in semi-tropical countries, partly on account of its economic value, but chiefly because of the reputation it enjoys as a means of overcoming malaria. Its sanitary powers appear to be established, numerous notoriously miasmatic stations and districts having been rendered healthful by its growth. It is probable that the destruction of the miasma is due not so much to emanations from the tree as to the fact that it evaporates water so rapidly from its innumerable large leaves as to drain the swamps and marshes in which it is planted. It is possible, however, that the large amount of volatile oil which must escape from it has some effect, and it is even affirmed (*A. J. P.*, 1875, p. 423) that the parasitic phylloxera will not attack grape-vines growing near it.

The eucalyptus oil of commerce is, indeed, composed chiefly of the oils of *E. amygdalina* and *E. dumosa*, which yield a very much larger product than does the official species. The oils of *E. piperita* and *E. hæmastoma* have a peppermint odor, and that of *E. citriodora* a citron-like odor, while the oil of *E. staigeriana* exactly resembles the oil of verbena; it is probable that these oils will come into commerce for the purposes of the perfumer.

Properties.—The leaves are the official portion of the plant and are officially described as follows: "Laminæ lanceolately scythe-shaped, from 8 to 30 cm. in length and from 2 to 7.5 cm. in breadth; summits when present acute or acuminate; bases unequal, obtuse or more or less rounded and connected with a twisted petiole from 5 to 35 mm. in length; margins slightly uneven, revolute; coriaceous; both surfaces varying from pale yellowish-green to grayish-green and more or less glaucous, glabrous, glandular-punctate and with numerous small, circular, brown dots of cork; veins of the first order anastomosing with each other and forming a line nearly parallel with the margin; odor slightly aromatic; taste aromatic, bitter, and cooling. Under the microscope sections of Eucalyptus show the upper and lower surfaces with nearly similar cells, the outer walls being strongly cuticularized; stomata occur on both surfaces, a region of palisade cells made up of from 3 to 4 rows of cells occurring beneath each surface; among the palisade cells occur large oil-secretion reservoirs, with a yellowish or orange colored oily content; calcium oxalate crystals in cells of the loose mesophyll in the form of rosette aggregates or monoclinic prisms varying from 0.015 to 0.025 mm. in diameter. At the periphery of the fibro-vascular bundles of the midrib and petiole occurs a more or less interrupted circle of small groups of slightly lignified bast-fibers." *U. S.*

Hans Kramer (*B. P. G.*, 1907, p. 319) presents an anatomical study of Eucalyptus with the characteristics of the drug in a powdered form.

In March, 1870, Cloez (*J. P. C.*, 4e sér., xii, 201) reported an elaborate chemical study of the eucalyptus leaves, and his results have been substantially confirmed by Debray (*De l'Eucalyptus Globulus*, Paris, 1872), Rabuteau (*Mém. de l'Académie*, Nov., 1872), and Broughton (*P. J.*, 3d ser., iii, 463). Cloez found, besides chlorophyll, resin, tannin, and inert substances, an essential oil, upon which the virtues of the drug appear to depend. Of this oil the fresh leaves afforded 2.75 parts per hundred, the recently dried leaves 6 parts; leaves which had been kept some time yielded a much smaller percentage. In the distillation, the oil for a time comes over freely at from 170° C. (338° F.) to 178° C. (352.4° F.); subsequently another portion of oil distils at 188° C. (370.4° F.) to 190° C. (374° F.), and finally a very minute portion does not volatilize until the temperature reaches 200° C. (392° F.). Cloez believes the oil to be composed of two camphors, differing in their volatility. The bulk of the oil yielded is the portion first distilled; to this Cloez has given the name of *eucalyptol*, or, as it is now also called, *cineol*, $C_{10}H_{18}O$. (See previous article.) Gildemeister and Hoffmann (*Aetherische Oele*, 1899, p. 690) divide the eucalyptus oils into 5 groups according to their constituents, viz.: Group 1, Cineol (or Eucalyptol) containing oils, of which group *Eucalyptus Globulus* is the most important; Group 2, Citronellal containing oils, of which group *Eucalyptus maculata* is the most important; Group 3, Citral containing oils, of which *E. staigeriana* F. von Muell., is the typical example; Group 4, Peppermint smelling oils, of which *Eucalyptus piperita* is an example; and Group 5, Less known oils of varying odor.

Schimmel & Co. (*Semi-Annual Report*, April, 1897) gave a list of some fifteen varieties of eucalyptus oils from the different Eucalyptus species. In their report for October, 1904, they give the sources and state the properties and components of 109 different eucalyptus oils obtained by them from Baker and Smith, Curators of the Technological Museum of Sydney, N. S. W.

According to Duquesnel, the oil of eucalyptus is adulterated—with alcohol, to be detected by means of fuchsin, which is insoluble in the pure oil but soluble in that containing even a very small percentage of alcohol; with fixed oil, to be detected by boiling with water, when the fixed oil remains on the surface; with volatile oil of copaiba or turpentine, to be detected by means of the boiling point, that of eucalyptol being 170° C. (338° F.), that of oil of turpentine 155° C. (311° F.), that of oil of copaiba 260° C. (500° F.). (*J. P. C.*, 4e sér., xvi, 45.)

Uses.—Whatever medicinal virtue eucalyptus possesses beyond a slight astringency is due to its volatile oil. Preparations of the crude drug are rarely used in this country. The leaves are occasionally rolled into cigarettes to be smoked for the relief of *bronchitis* or *asthma*. For therapeutic properties of the oil of eucalyptus, see page 762.

Dose, of eucalyptus, ten to thirty grains (0.65–2 Gm.); of the oil, five to ten minims (0.3–0.6 mil).

Off. Prep.—Fluidextractum Eucalypti, *U. S.*

EUGENOL. U. S.

EUGENOL

(eū′ǧe-nōl)

"An unsaturated, aromatic phenol [$C_{10}H_{12}O_2$ or $C_6H_3.C_3H_5.OCH_3.OH$ 1:3:4 = 164.10] obtained from oil of clove and from other sources. Preserve it in well-closed containers, in a cool place, protected from light." *U. S.*

Allylguaiacol, Allylmethylpyrocatechol; Eugenol, *Fr.;* Oleum Caryophyllorum, *P. G.;* Eugenol, *G.*

Eugenol is extracted on a large scale from oil of cloves and utilized as the starting point in the manufacture of artificial vanillin. (See *Vanillinum.*) It is also found in pimenta, cinnamon leaves, sassafras, canella, bay and other plants. It is officially described as "a colorless or pale yellow, thin liquid, having a strongly aromatic odor of clove, and a pungent and spicy taste. Exposure to air causes it to become darker and thicker. Eugenol is miscible with alcohol, chloroform, ether or fixed oils; it is soluble in twice its volume of 70 per cent. alcohol. A mixture of 1 part of Eugenol and 20 parts of hot distilled water is only very slightly acid to litmus. Specific gravity: 1.064 to 1.070 at 25° C. (77° F.). It boils between 250° and 255° C. (482° and 491° F.). It is optically inactive and strongly refractive. Dissolve 1 mil of Eugenol in 12 mils of sodium hydroxide T.S. and add 18 mils of distilled water; a clear solution results, which becomes turbid when exposed to air. Shake 1 mil of Eugenol with 20 mils of distilled water and filter; 5 mils of the clear filtrate, upon the addition of 1 drop of ferric chloride T.S., shows a transient, grayish-green color, but not a blue or violet color (*phenol*)." *U. S.*

Uses.—Eugenol may be used for flavoring purposes as oil of cloves.

Dose, two to five minims (0.12–0.3 mil).

Off. Prep.—Mistura Olea Balsamica, *N. F.*

EUONYMI CORTEX. Br.

EUONYMUS BARK

(eū-ŏn′y-mī cŏr′tĕx)

"The dried root bark of Euonymus atropurpureus, *Jacq.*" *Br.* "The dried bark of the root of *Euonymus atropurpureus* Jacquin (Fam. *Celastraceæ*), without the presence of more than 3 per cent. of wood or other foreign matter." *N. F.*

Euonymus, *N. F. IV,* Wahoo; Cortex Euonymi; American Indian Arrow-wood; Ecorce d'Evonymus, *Fr. Cod.:* Spindlebaum, Pfaffenhütchen, Spillbaumrinde, *G.*

Euonymus (*Evonymus*) ***atropurpureus,*** named variously ***wahoo, spindle-tree,*** and ***burning-bush,*** is a tall, erect shrub, with quadrangular branchlets, and opposite, petiolate, oval-oblong, pointed, serrate leaves. The flowers, which stand in loose cymes on axillary peduncles, are small and dark purple, with sepals and petals commonly in fours. The capsule or pod is smooth and deeply lobed. The plant is indigenous, growing throughout the Northern and Western States, and sometimes cultivated for the beauty of its crimson fruit.

The plants belonging to this genus are shrubs or small trees, presenting in the autumn a striking appearance from the rich red color of their fruit, which has obtained for them the name of *burning-bush. E. americanus* L. and *E. europæus* L. have been cultivated in gardens as ornamental plants. Two or more of the species have been used in medicine. Their properties are probably similar, if not identical. Grundner, who experimented with the fruit of *E. europæus,* found it to have no other effect than that of a diuretic. (*Ph. Cb.,* 1847, p. 873.) An oil expressed from the seeds is used in Europe for the destruction of vermin in the hair, and sometimes also as an application to old sores. (*Ibid.,* 1851, p. 641.) Griffith says that the seeds of this and other species are purgative and emetic, and that the leaves are poisonous to sheep and other animals feeding on them. He states also that the inner bark of *E. tingens* Wall. is beautifully yellow, and used in India for dyeing, and in diseases of the eye. (*Med. Bot.,* p. 220.) It is probable that much of the wahoo of our drug stores has been obtained from *E. americanus,* which is distinguished from *E. atropurpureus* by its rough, warty, depressed pods, and almost sessile, thickish leaves.

Properties.—The dried bark is described in the National Formulary as follows: "Usually in transversely curved pieces, occasionally in single quills from 2 to 7 cm. in length; bark from 1 to 2.5 mm. in thickness; very light in weight; outer surface grayish or light brown, somewhat wrinkled, occasionally transversely fissured from the lenticels and with scale-patches of soft cork; inner surface grayish-white, longitudinally striate and somewhat porous; fracture short with silky, projecting elastic fibers. Odor distinct· taste bitter and acrid. The powder is light brown, and when examined under the microscope shows numerous starch grains, nearly spherical, from 0.003 to 0.012 mm. in diameter; fragments of cork with nearly colorless, thin walls; secretion cells with yellowish or brownish amorphous contents; bast fibers very long, with thin, non-lignified walls possessing numerous small, more

or less oblique pores; numerous fragments of starch-bearing parenchyma; calcium oxalate in rosette aggregates from 0.015 to 0.035 mm. in diameter, the amount in different specimens showing some variation. Euonymus yields not more than 12 per cent. of ash." *N. F.*

"In quilled or curved pieces, from two to four millimetres thick. Outer layer a soft, friable, greyish cork, marked with dark patches. Inner surface pale tawny-white and smooth. Fracture short, the fractured surface yellowish in color. Transverse section free from sclerenchymatous cells and fibres, and exhibiting, in the secondary bast, laticiferous cells filled with a granular, elastic substance. Faint but characteristic odor; taste somewhat mucilaginous, afterwards bitter and slightly acrid." *Br.*

The drug frequently has as much as 25 per cent. of adhering wood. The amount of the latter with other foreign matter should not exceed 3 per cent. Holm (*Merck's Rep.*, 1909, p. 169) illustrates the structural characteristics of *E. atropurpureus* and *E. americanus*. Holmes (*P. J.*, 1905) describes the bark of *Alstonia scholaris* which has been used as an adulterant of Euonymus. The name of Wahoo or Waahoo (pronounced *Wawhoo*) was given to it by the Indians. The same name has also been applied to *Ulmus alata*, of the Southern States, and has thus led to mistakes.

It imparts its virtues to water and alcohol. Analyzed by Wm. T. Wenzell, it was found to contain a bitter principle which he named *euonymin*, asparagin, a soft resin, a crystallizable resin, a yellow resin, a brown resin, fixed oil, wax, starch, albumen glucose pectin, and various salts of organic and inorganic acids. Euonymin was obtained by agitating with chloroform a tincture made with diluted alcohol, separating the chloroformic solution and allowing it to evaporate spontaneously, treating the residue with ether, dissolving what was left in alcohol, adding lead acetate to the solution, filtering, precipitating the lead with hydrogen sulphide, and evaporating. The euonymin obtained was uncrystallizable, intensely bitter, soluble in water and alcohol, and neutral in its reactions. It was abundantly precipitated from its solution by lead subacetate and phosphomolybdic acid. For an examination of commercial *euonymin* (the eclectic resinoid) by Paul Thibault, see *N. R.*, 1883, 294. W. P. Clothier found the bark to yield no volatile oil on distillation. According to the same writer, if a concentrated tincture be poured into water, a dark yellow substance will be thrown down, containing resin and fixed oil, which is the *euonymin* of the eclectics, very improperly so named, as, though it contains a portion of the active principle, it is a very complex substance. Clothier found the bark to purge actively without griping. (*Ibid.*, 1861, p. 491.) Frank V. Cassaday (*A. J. P.*, 1889, p. 284) found 1.30 per cent. of volatile oil and resin, 1.48 per cent. of *euonic acid* and resin, 2.10 per cent. of euonymin and resin, together with the usual plant constituents. Kubel has discovered in the fresh inner bark of *E. europæus* a saccharine, crystallizable substance, closely resembling mannite, but differing in its crystalline form and in its melting point. He calls it *euonymite*. (*J. P. C.*, Dec., 1862, 523.)

H. Rogerson (*Ph. J.*, 1912, p. 687) has made a complete chemical examination of this bark with the result that the following definite constituents are reported present: *dulcitol; furan B carboxylic acid*, $C_5H_4O_3$; *euonymol*, $C_{21}H_{30}O_4$ (a new crystalline alcohol, having a melting point of 248° C. [478.4° F.]); a sugar which yielded *d-phenyl glucozazone; euonosteryl*, $C_{31}H_{51}O.OH$; *homoeuonosteryl*, $C_{40}H_{69}O.OH$; *atropurol*, $C_{27}H_{44}(OH)_2$; *citrullol*, $C_{32}H_{36}O_2(OH)_2$; and a mixture of palmitic, cerotic, oleic and linoleic acids. No glucoside was found nor could any product corresponding to the *euonymin* of Wenzell or of Schmiedeberg be found.

Uses.—This bark was first introduced into notice, as a remedy for *dropsy*, under the name of Wahoo, by George W. Carpenter. It exerts a digitalis-like action on the heart, but because of the irregularity of its absorption should not be employed as a systemic remedy. By virtue of its local irritant effects on the intestines it usually exerts a laxative effect but is not to be recommended because of its liability to nauseate and the possibility of circulatory effects. It was formerly used as a diaphoretic in *muscular rheumatism, influenza, acute coryza*, and similar conditions but it does not appear to have any advantage for this purpose over the other nauseating drugs and has been largely abandoned. The fluidextract may be given in doses of eight minims (0.5 mil).

Dose, of euonymus, five to fifteen grains (0.32–1.0 Gm.).

"*Caution.*—It has been stated that the absorption of Euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient." *N. F.*

EXTRACTA

EXTRACTS

(ęx-trăc'tą)

Extraits, *Fr.;* Extrakte, *G.;* Estratti, *It.;* Extractos, *Sp.*

Extracts, as the term is employed in the Pharmacopœias, are solid preparations, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing a dried drug to the action of a solvent, or by expressing the juice from a fresh plant. A distinction was formerly made between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of plants, the former being called *Extracta*, the latter *Succi Spissati*, but the distinction has

been generally abandoned. There is no such essential difference between these two sets of preparations as to require that tney should be separately classed, and something is gained in the simplicity of nomenclature, as well as of arrangement, which results from their union.

The composition of extracts varies with the nature of the vegetable, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principle of the plant with as little of the inert matter as possible, though sometimes it may be desirable to separate two active ingredients from each other when their effects upon the system are materially different; this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, coloring matter, salts, and the peculiar principles of plants, to which, when an alcoholic solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil, gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in this commentary. There is one, however, which from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place. We allude to *extractive*, or, as it is sometimes called, *extractive matter*.

It has long been observed that in most vegetables there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes chemical change during the process of evaporation, imparting to the liquid even if originally limpid, first a greenish, then a yellowish-brown, and ultimately a deep brown color, and becoming itself insoluble. This substance, originally called *saponaceous matter* by Scheele, afterwards received the more expressive name of *extractive*, derived from its frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted, by some chemists, who consider the phenomena supposed to result from its presence as depending upon the mutual reaction of other principles. The most important property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, while the other ingredients may remain. The name of oxidized extractive which has been given to it is incorrect, and Berzelius proposed to substitute for it that of *apothem*, synonymous with deposit. According to Berzelius, apothem is not completely insoluble in water, but imparts a slight color to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, and to carry them along with it, thus acquiring properties somewhat different according to the source from which it is obtained. In this way also, even when the extractive of a plant is itself medicinally inert, its conversion into apothem may be injurious by causing a precipitation of a portion of the active principle, and in practical pharmaceutical operations this change should always, if possible, be avoided. We shall treat of the subject under the several heads of (1) the extraction of the soluble principles from the plant; (2) the method of conducting the evaporation; (3) the proper condition of extracts, the changes they are liable to undergo, and the best method of preserving them.

1. *Extraction of the Soluble Principles.*

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract: (1) by expression alone; (2) by the agency of a solvent, with or without expression.

1. By Expression.—This method is applicable to recent vegetable substances. All plants cannot be usefully treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of the succulent a considerable portion do not yield all their active principles with their juice. Succulent fruits, and various acrid and narcotic plants, are proper subjects for this treatment. The plants should be operated upon, if possible, immediately after collection. Battley, of London, recommended that, if not entirely fresh, they should be revived by the immersion of the stalks in water for twelve or eighteen hours, and those only used which recover their freshness by this management. They should then be cut into pieces, and bruised in a stone mortar till brought to a pulpy consistence. When the plant is not very succulent, it is necessary to add a little water during this part of the process, in order to dilute the juice. After sufficient contusion, the pulp is introduced into a linen or canvas bag, and the liquid parts expressed. Brande states that light pressure only should be employed, as the extract is thus procured greener, of a less glutinous or viscid consistence, and, in his opinion, more active than when considerable force is used in the expression. (See Remington's *Practice of Pharmacy*.) The juice thus obtained is opaque, and usually green, in consequence of the presence of green wax or chlorophyll, and of a portion of the undissolved vegetable fiber in minute division. By heating the juice to about 71.1° C. (160° F.) the albumen contained in it

coagulates, and, involving the chlorophyll and vegetable fiber, forms a greenish precipitate. If the liquid be now filtered, it becomes limpid and nearly colorless, and is prepared for evaporation. The clarification, however, is not absolutely necessary, and is generally neglected. Sometimes the precipitate carries with it a considerable portion of the active principle, in which case it should be subsequently incorporated with the juice, when reduced by evaporation to the consistence of syrup. Ether added to the expressed juices of plants enables them to be kept long without injurious change. Lepage, of Gisors, France, has kept the juice of belladonna in this way more than ten years, and found it, at the end of that time, to yield an extract identical in physical, chemical, and physiological properties with that obtained from the fresh juice. If this fact is found to be of general applicability, it will be of considerable importance, as enabling the pharmacist to supply himself at pleasure with extracts to be relied on, without reference to the season.

2. By Solution.—The active principles of dried vegetable substances can be extracted only by means of a liquid solvent. The menstruum usually employed is either water or alcohol, or a mixture of the two. Water, on account of its cheapness, is always preferred, when circumstances do not strongly call for the use of alcohol. It has the advantage, moreover, that it may be assisted in its action if necessary by a higher degree of heat than the latter. Tap water is often unfit for the purpose, in consequence of the quantity of its saline matter, which in some instances may exert an unfavorable influence on the active principle, and must always be left in the extract. Rain, or distilled water should be preferred. Alcohol is employed when the principles to be extracted are insoluble or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils; when the reaction of the water itself upon the vegetable principles is injurious; and, finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The aqueous solution requires to be quickly evaporated, as this fluid rather promotes than counteracts chemical changes, while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former is preferable, and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively than of both united. Extracts obtained by the agency of water are called *aqueous extracts;* those by means of alcohol, undiluted or diluted, *alcoholic* or *spirituous extracts.* Sometimes the term *hydro-alcoholic* is applied to extracts obtained by the joint agency of alcohol and water.

Chloroform is frequently used to saturate the water used in making aqueous extracts to prevent fermentation during percolation.

The method of preparing the solution is not a matter of indifference. The drug should be thoroughly bruised, or reduced to a coarse powder, so as to allow the access of the solvent to all its parts, and yet not so finely pulverized as to prevent a ready precipitation of the undissolved or inactive portion. When water is alone employed, it has been customary to boil the medicine for a considerable time, and, if the first portion of liquid does not completely exhaust it, to repeat the operation with successive portions until the whole of the active matter is extracted. This may be known by the sensible properties of the liquid, and by its influence upon reagents. But the boiling temperature produces the decomposition of many vegetable principles, or at least so modifies them as to render them inert, and the extracts prepared by decoction are usually less efficient than those made with a less degree of heat. From numerous experiments upon extracts, Orfila concluded that their virtues were less in proportion to the heat employed. It has, therefore, been recommended to substitute for decoction the process of maceration, digestion, or hot infusion, in the first of which the liquid acts without heat, in the second is assisted by a moderately increased temperature sustained for a considerable time, and in the third is poured boiling hot upon the vegetable matter and allowed to stand for a short period in a covered vessel. When the active principles are readily soluble in cold water, *maceration* is often preferable to the other modes, as starch, which is inert, is thus left behind; but in many instances the preparation would spoil before the extraction would be completed. By *digestion,* though the solvent power of water is moderately increased, the advantage is often more than counterbalanced by the increased disposition to spontaneous decomposition. *Hot infusion,* therefore, is to be preferred where the vegetable substance does not readily yield its virtues to cold water. It has the advantage, moreover, in the case of albuminous substances, that the albumen is coagulated, and thus prevented from increasing the bulk of the extract, without adding to its virtues. A convenient mode of performing this process is to introduce the solid material into a vessel with an opening near the bottom temporarily closed, or into a funnel having a notched cork in its mouth, then to pour on the boiling water, and, having allowed it to remain a sufficient length of time, to draw it off through the opening. This operation may be repeated until the water comes away without any obvious impregnation.

It is always desirable to obtain the solution in

the first place as concentrated as possible, so as to prevent the necessity of long continued evaporation, which injures the extract. It is better, therefore, to incur the risk, both when decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it.

Sometimes filtering a turbid infusion or decoction, before evaporation, causes the resulting extract to keep better by removing substances which, beside undergoing decomposition, may act as a ferment, and occasion the decomposition of the active matter of the extract.

When alcohol is employed as a menstruum, the vegetable substance should be macerated in it for one or two weeks, and care should be taken that the tincture be as nearly saturated as possible. The extraction may be hastened by substituting digestion for maceration, as the moderate heat employed, while it facilitates the action of the alcohol, has in this case no effect in promoting decomposition, and the influence of the atmospheric air may be excluded by performing the process in close vessels.

Acetic acid has been introduced into use as a menstruum in the preparation of extracts. It is supposed to be a better solvent of the active principles of certain substances than either water or alcohol alone. According to Girolamo Ferrari, the acrid narcotics, such as aconite, hemlock, hyoscyamus, and stramonium, yield much stronger extracts with distilled vinegar than with water, and still stronger with alcohol to which strong acetic acid has been added. (*J. P. C.*, 3e sér., i, 239.) Experiments have shown that strong acetic acid (60 per cent.) is a powerful solvent for the active properties of various drugs, particularly those which contain volatile oils, and in many cases a 10 per cent. acetic acid is an excellent menstruum for making extracts; for these the name *acetract* has been proposed. (*Proc. A. Ph. A.*, 1897, 416.) E. R. Squibb has used acetic acid largely for extracts. (*West. Drug.*, 1897, 123.)

Ether also is now used to a considerable extent in the preparation of certain extracts. Having the property of dissolving volatile oil and resin, and of evaporating at a temperature insufficient to volatilize the oil, it is admirably adapted for the preparation of extracts from those substances the virtues of which reside in the two principles referred to. An ethereal tincture is first prepared by the process of percolation, and the ether is then allowed to escape by spontaneous evaporation, or distilled off at a very moderate heat. The oleo resinous extracts thus obtained are usually of a thick fluid or semi-fluid consistence. Several of them now rank among the official preparations, in the U. S. P., under *Oleoresinæ*. Acetone is another solvent used much for the same purpose as ether.

The process of *percolation* has in this country been very advantageously applied to the preparation of extracts, both with water and spirituous menstrua. It has the following great advantages: (1) that it enables the soluble principles to be sufficiently extracted by cold water, thereby avoiding the injury resulting from heat in decoction and hot infusion (2) that it effects the extraction much more quickly than can be done by maceration, thereby not only saving time, but also obviating the risk of spontaneous decomposition; and (3) that it affords the opportunity of obtaining highly concentrated solutions, thus diminishing the injurious effects of the subsequent evaporation. While thus advantageous, it is less liable in this particular case than in others to the objection of yielding imperfect results if not well performed, for, though an inexpert or careless operator may incur loss by an incomplete exhaustion of the substance acted on, and the extract may be deficient in quantity, it may still be of the intended strength and quality, which is not the case with infusions or tinctures unskilfully prepared upon this plan. In the process of percolation the drug must first be reduced to the proper degree of fineness. The U. S. P. (8th Rev.) gives the following directions.

Fineness of Powder.—The fineness of powder is expressed, in the Pharmacopœia, either by descriptive words (generally so in the case of brittle or easily pulverizable substances), or in terms expressing the number of meshes to a linear inch of the sieve through which the powder will pass. The corresponding values, in terms of metric measures of length, are added below in parentheses, but it has not been deemed advisable, in this revision, to substitute them in the text of the Pharmacopœia for those at present in use. The diameter of the wire (gauge number) used in making sieve cloth has an important influence upon the size of the mesh, and it is necessary to specify in each case the thickness of the wire, and it was so specified in the U. S. P. VIII but the U. S. Bureau of Standards, owing to the different standards in use by manufacturers of wire gauze determined to standardize the diameter of the particles of the powders, and the U. S. P. IX provides the following statement: "The fineness of powders and granular substances is expressed, in the Pharmacopœia, by numbers which originally represented only the meshes per inch of the sieve through which the powders would pass. Fineness, so used, has been redefined below in terms of the maximum diameter of the particles of the powder as measured by the width of the opening of the meshes of the sieves from which they receive their designating numbers. A powder of a specified number must meet the requirements given below for that number of powder, but the larger proportion of it must not pass through a sieve of a lower degree of fineness.

Number of Powder.		Diameter of Particles
No. 100	Powder has a fineness, in diameter of particles, less than	0.14 millimeter.
No. 80 Very fine powder	Powder has a fineness, in diameter of particles, less than	0.17 millimeter.
No. 60 Fine powder	Powder has a fineness, in diameter of particles, less than	0.23 millimeter.
No. 50 Moderately fine powder	Powder has a fineness, in diameter of particles, less than	0.28 millimeter.
No. 40 Moderately coarse powder	Powder has a fineness, in diameter of particles, less than	0.38 millimeter.
No. 30	Powder has a fineness, in diameter of particles, less than	0.54 millimeter.
No. 20 Coarse powder	Powder has a fineness, in diameter of particles, less than	0.85 millimeter
No. 12 Very coarse powder	Powder has a fineness, in diameter of particles, less than	1.47 millimeters.
No. 6	Powder has a fineness, in diameter of particles, less than	3.00 millimeters.

The degree of fineness defined above shall be such as are determined by sieving tests made with sieves of the Standard Screen Scale recommended by the Bureau of Standards." *U. S.*

Percolation, as directed in the U. S. Pharmacopœia IX "consists in subjecting a comminuted substance or a mixture of substances, contained in a vessel called a percolator, to the solvent action of successive portions of a liquid termed the menstruum in such a manner that the liquid, as it traverses the powder in its descent to the receiver, shall extract the soluble constituents, and pass from the percolator free from insoluble matter.

"When the process is successfully conducted, the first portion of the liquid, or percolate, passing through the percolator will be nearly saturated with the soluble constituents of the substance treated; and if the quantity of menstruum be sufficient for its exhaustion, the last portion of the percolate will be nearly free from color, odor, and taste, other than those of the menstruum itself.

"In preparations which direct the process of percolation, wherever the expression 'until the drug is exhausted' or a similar phrase occurs, it is to be understood that the term 'exhausted' means the point at which the valuable constituents have been as completely extracted as is possible or practical, and this must be determined by the judgment and experience of the operator.

"*Percolators.*—The following statement with regard to percolators and the process of percolation is given in order to illustrate a method of percolation. It is not intended as compulsory and it is permissible for manufacturers and others to modify the process to suit their needs. The percolator most suitable for the quantities contemplated by this Pharmacopœia should be nearly cylindrical, or slightly conical, with a funnel-shaped termination at the smaller end. The neck of this funnel-end should be rather short, and should gradually and regularly become wider toward the orifice, so that a perforated cork, bearing a short glass tube, may be tightly wedged into it. The glass tube, which must not project above the inner surface of the cork, should extend from 3 to 4 cm. beyond the outer surface of the cork, and should be provided with a closely fitting rubber tube, at least one-fourth longer than the percolator itself, and ending in another short glass tube, whereby (when it is desired to interrupt the percolation) the rubber tube may be so suspended that its orifice shall be above the surface of the menstruum in the percolator, a rubber band holding the tube in position.

"The shape of a percolator should be adapted to the nature of the drug to be operated upon. For drugs which are apt to swell, particularly when a feebly alcoholic or an aqueous menstruum is employed, a *conical* percolator is preferable. A *cylindrical* or only slightly tapering percolator may be used for drugs which are not liable to swell, particularly if difficult to exhaust, also when the menstruum is strongly alcoholic, or when ether or some other volatile liquid is used for extraction. The size of the percolator selected should be in proportion to

the quantity of drug extracted. When properly packed in the percolator, the drug should not occupy more than two-thirds of its height. The percolator is best constructed of glass, but, unless otherwise directed, may be made of any suitable material not affected by the drug or menstruum. For hot percolation glass percolators are unsuited, as they are liable to fracture. Metallic percolators in such cases are required.

"The percolator is prepared for percolation by gently pressing a small tuft of purified cotton into the neck, and this may then be moistened by pouring a few drops of menstruum upon the cotton, to facilitate the passage of the first portion of percolate, which is often very dense.

"*The Process.*—The powdered substance to be percolated (which should be uniformly of the fineness directed in the formula, and should be perfectly air-dry before it is weighed) is put into a suitable dish, sufficient menstruum is poured on, and the powder thoroughly stirred until it is uniformly moistened. The moist powder is then passed through a coarse sieve—No. 40 powders, and those which are finer, requiring a No. 20 sieve, and No. 30 powders require a No. 15 sieve for this purpose. Powders of a less degree of fineness usually do not require this additional treatment after the moistening. The moist powder is now transferred to a sheet of thick paper and the whole quantity poured from this into the percolator. It is then shaken down lightly and allowed to remain in that condition for a period varying from fifteen minutes to several hours, unless otherwise directed; after which the powder is pressed, by the aid of a plunger of suitable dimensions, more or less firmly, in proportion to the character of the powdered substance and the alcoholic strength of the menstruum, strongly alcoholic menstrua, as a rule, permitting firmer packing of the powder than the weaker. The percolator is now placed in position for percolation, and, the rubber tube having been fastened at a suitable height, the surface of the powder is covered by an accurately fitting disk of filtering paper, held in place by a glass stopper or percolator weight, and a sufficient quantity of the menstruum poured on through a funnel reaching nearly to the surface of the paper. If these conditions are accurately observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached, in this, a height corresponding to its level in the percolator, which is now closely covered to prevent evaporation. The apparatus is then allowed to stand at rest for the time for maceration specified in the formula.

"To begin percolation, the rubber tube is lowered and its glass end introduced into the neck of a bottle previously marked for a quantity of liquid to be received, if the percolate is to be measured, or of a tared bottle, if the percolate is to be weighed; and by raising or lowering this receiver the rapidity of percolation may be increased or decreased as may be desirable. A layer of menstruum must constantly be maintained above the powder, so as to prevent the access of air to its interstices, until all has been added, or the requisite quantity of percolate has been obtained. This is conveniently accomplished, if the space above the powder will admit of it, by inverting a bottle containing the entire quantity of menstruum over the percolator in such a manner that its mouth may dip beneath the surface of the liquid, the bottle being of such shape that its shoulder will serve as a cover for the percolator.

"Unless otherwise directed when the dregs of a tincture, or of a similar preparation, are to be subjected to percolation, after maceration with all or with the greater portion of the menstruum, the liquid portion should be drained off as completely as possible, the solid portion packed in a percolator, as before described, and the liquid poured on, until all has passed from the surface, when immediately a sufficient quantity of the directed menstruum should be poured on to displace the retained liquid, until the prescribed quantity has been obtained.

"*Repercolation or Fractional Percolation.*—Authority is given to employ, where it may be applicable, the process of repercolation, without change of the initial menstruum. This process is used in Type Process C for fluidextracts (see page 484).

"*Rate of Flow.*—It is obvious that the success of the process of percolation largely depends upon the regulation of the flow of the percolate; if this should be too rapid, incomplete exhaustion will result, but if too slow, valuable time may be wasted. The rate of flow for fluidextracts for 1000 Gm. of powder should not exceed ten drops a minute; for official quantities of tinctures and preparations of about the same strength twenty drops a minute, and the word 'slowly' throughout the text is understood to mean a rate of flow corresponding to this; it is evident that the proper rate of flow should vary with the quantity and character of the drug employed and the density of the menstruum.

"*Maceration.*—Percolation is not suitable for exhausting some drugs, and the process of maceration is employed for some of the tinctures (Aloes, Asafetida, Sweet Orange Peel, Tolu, etc.). Specific directions will be found in the text, and maceration should be conducted preferably at a temperature of from 15° to 20° C. (59°–68° F.)." *U. S.*

For an account of E. R. Squibb's process of repercolation, see *Fluidextracta.*

Some prefer the mode of expression to that of percolation. This also is applicable both to aqueous and to alcoholic menstrua. The substance to be acted upon is mixed with the menstruum, cold or hot according to circumstances, and the mixture is allowed to stand from twelve to twenty-four hours. The liquid part is then filtered off, and the remainder submitted to strong pressure, in a linen bag, by means of a common screw press, or other convenient apparatus. Another portion of the men-

struum may then be added, and pressure again applied, and, if the substance is not sufficiently exhausted, the same operation may be performed a third time. Frequently only a single expression is required, and very seldom a third. The quantity of menstruum added must vary with the solubility of the principles to be extracted. According to Mohr, the method of expression has the advantages over that of the percolation, that it yields solutions of more uniform concentration, that it does not require the materials to be so carefully powdered, or otherwise so skilfully managed, in order to insure favorable results, and, finally, that it occupies less time.

2. *Mode of Conducting the Evaporation.*

In evaporating the solutions obtained in the modes above described, attention should always be paid to the fact that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapor. The operator should, therefore, observe two rules: (1) to conduct the evaporation at as low a temperature as is consistent with other objects; (2) to exclude atmospheric air as much as possible, and, when this cannot be accomplished, to expose the liquid the shortest possible time to its action. The injurious influence of atmospheric air is much greater at the boiling point of water than at a less heat, even allowing for the longer exposure in the latter case, and therefore a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. Bearing these principles in mind, we shall proceed to examine the different modes in practice. First, however, it is proper to observe that decoctions generally let fall, upon cooling, a portion of insoluble matter, and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble substance formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposits on cooling, and as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a rule, is to allow it to remain.

The method of evaporation formerly resorted to in the case of aqueous solutions is rapid boiling over a fire. The more quickly the process is conducted, the better, provided the liquid is to be brought to the boiling point, for the temperature cannot exceed this, and the length of exposure is diminished. But, where this method is employed, it should never be continued until the completion of the evaporation, for when most of the water has escaped, the temperature can no longer be kept down to the boiling point, and the extract is burnt. The caution, therefore, should always be observed of removing the preparation from the fire before it has attained the consistence of thick syrup, and completing the evaporation, either by means of a water bath, or in shallow vessels at a moderate heat. When large quantities of liquid are to be evaporated, it is best to divide them into portions and evaporate each separately, for, as each portion requires less time for evaporation than the whole, it will thus be a shorter time exposed to heat. But the mode of evaporation by boiling is always objectionable, and should be employed only in cases where the principles of the plant are so fixed and unchangeable as to authorize their extraction by the method of decoction.

Evaporation by means of a water bath, from the commencement of the process, is safer than the plan just mentioned, as it obviates all danger of burning the extract; but, as the heat is not supplied directly from the fire, the volatilization of the water cannot go on so rapidly, and, the temperature being nearly the same, when the water bath is kept boiling, there is greater risk of injurious action from the air. The liquid should be stirred during the process. The use of the steam bath has become very general in this country, as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while sufficient to evaporate it, may be less than 100° C. (212° F.). The apparatus consists of an ordinary boiler, containing water, the vapor of which is conducted through a pipe into the evaporating vessels, communicating with each other by means of iron steam pipes. These vessels have the form of an ordinary copper basin, to the inside of which is riveted a shallow tinned copper evaporating basin, intended to contain the liquid to be evaporated. The vapor from the boiler circulates between these vessels, and the water into which it condenses is allowed to escape through a steam valve attached to the bottom of each vessel. The liquid to be evaporated is first distributed in two or three basins, but when considerably concentrated, is transferred to a single one, where it is stirred towards the close of the process to hasten the evaporation. The heat applied to the liquid can be easily regulated by the steam valves.

As the heat capable of being applied by boiling water to the evaporating liquid does not exceed 93.3° C. (200° F.), while that by steam can, by a moderate pressure, be increased to the boiling point or beyond it, the evaporation by the latter agency may be much more rapid than by the former, when the pressure is from ten to twenty pounds to the square inch; so that there is a temptation to raise the heat to a degree seriously injurious to the product. Evaporation, therefore, by steam heat always requires caution and a stirring device should be used. The water bath is much less liable to be abused. In this respect the latter method has the advantage.

A good plan of evaporation, though slow, is to place the liquid in a broad, shallow vessel, exposed in a stove or drying room to a temperature of about 37.8° C. (100° F.), or a little higher, taking care that the air have free

access in order to facilitate the evaporation. This mode is particularly applicable to those cases in which maceration or infusion is preferred to decoction for extracting the active principles. Berzelius says that we may thus usually obtain the extract in the form of a yellowish transparent mass, while extracts prepared in the ordinary way are almost black, and are opaque even in very thin layers. Even when the liquid is boiled at first, the process may often be advantageously completed in this manner. It has been proposed to effect the evaporation at the common temperature, by directing a strong current of air, by means of a pair of smith's bellows, over the surface of the liquid, and in reference to substances which are injured by heat and not by atmospheric air the plan will be found useful.

Plans have been proposed and carried into execution for performing evaporation without the admission of atmospheric air. The apparatus for *evaporation in vacuo,* now largely used by manufacturing pharmacists, is well calculated to meet this object, at the same time that, by removing the atmospheric pressure, it enables the water to rise in vapor more rapidly, and at a comparatively low temperature.

A convenient plan of excluding the air, though it does not at the same time meet the object of reducing the degree of heat, is to distil off the water in close vessels. Berzelius says that this is the best mode of concentration next to that *in vacuo.* Care, however, must be taken that the fire be not too long applied, lest the extract should be burnt. The process should, therefore, be completed by means of the water bath.

In the concentration of alcoholic solutions, distillation should always be performed, as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. Here also the water bath should be employed, to obviate any possible risk of injury from the fire. When the decoction or infusion and the tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together while they are of such a consistence as to incorporate without difficulty. The object of this separate evaporation is that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat therefore, should be applied to the bottom and not to the sides of the vessel.

Inasmuch as the yield of extracts is largely dependent on the character of the menstruum used in the percolation, it follows that there must necessarily be a great variation in the strength of commercial extracts. C. H. LaWall has prepared a valuable table giving the yield of extract by various drugs. (*Proc. A. Ph. A.,* 1897, 414.) For methods of assay, see various official processes.

"**Pilular Extracts** are solid or semi-solid products prepared by exhausting drugs with appropriate solvents and carefully evaporating the solutions to the proper consistence. These extracts preserve the useful constituents of the drug in a concentrated, relatively uniform and permanent condition, and in a form suitable for medication.

"The solvents or menstrua employed in the preparation of pilular extracts are water, alcohol, or mixtures of these in the proportions stated in the formulas. A few drugs require for their extraction the addition of an acid or an alkali to the solvent. Where alcohol is used in the extraction it may be recovered by distillation.

"In the preparation of pilular extracts the concentration of the solutions should be completed without delay, and undue exposure to heat must be avoided. The limit of temperature for the evaporation, as stated in the formulas, should not be exceeded. In the manufacture of these extracts on a large scale an apparatus for distilling and evaporating under reduced pressure should be used. It is also important that the residue be frequently stirred so as to hasten the evaporation and to obtain a uniform product.

"Pilular extracts are extensively used in pill masses and in ointments and, to facilitate their use in these preparations, the degree of concentration is commonly directed to be that of a 'pilular consistence.'

"Pilular extracts should be protected from exposure to sunlight and air by being kept in tightly-covered glass or earthen-ware containers.

"**Powdered Extracts** differ from pilular extracts in that they are dry, fine powders. Powdered extracts are often preferred to pilular extracts for general use, because they can be more accurately weighed, more easily dispensed, and more conveniently preserved in tightly-stoppered bottles.

"In the preparation of powdered extracts, it is necessary to use solvents that will extract the active principles of the drugs, and only a minimum amount of the inert substances. Where the drug contains an oily constituent that would be extracted by the menstruum directed, it becomes necessary to adopt in the process of manufacture a method for the separation of this oil so that the product will retain a satisfactory, pulverulent form.

"The concentration of the liquids containing the extractive should be completed without delay and undue exposure to heat must be avoided.

"The limit of temperature as stated in the formulas should not be exceeded, and the use of apparatus for concentrating under reduced pressure is recommended. The final drying of the soft extract can be greatly facilitated by spreading it upon plates of glass or tinned metal

and exposing it to currents of warm, dry air. Powdered extracts must be thoroughly dried, powdered and mixed with the diluent and preserved in tightly-stoppered, small, wide-mouthed, amber-colored bottles, and stored in a cool and dry place.

"Alkaloidal standards have been adopted for Extracts that can be reliably assayed. Assay methods are directed for the determination of their strength, and to provide for standardization. When necessary, an inert diluent is directed to reduce the product to the standard. In the official formulas glucose is directed for the diluent in pilular extracts and dried starch and magnesium oxide are directed for powdered extracts, but it is permissible for the manufacturer to use as inert diluents for the latter, sugar, sugar of milk, powdered glycyrrhiza, magnesium carbonate or the finely powdered drug or marc from which the respective extract was made. For the convenience of the prescriber, the standards of strength for the Extracts have been adjusted, wherever possible, so that each bears a definite relation to that of the respective drug of average strength, and a statement of the standard precedes the formula," *U. S.*

3. *Condition and Preservation of Extracts.*

Extracts may be prepared of three different degrees of consistence: soft, so that they may be readily made into pills, hard, in order that they may be pulverized, and in a fine, dry powder. The soft extracts always contain a notable percentage of water. In astringent extracts, the evaporation should be carried to dryness. Those obtained from the expressed juices of plants are apt to attract moisture from the air, in consequence of the deliquescent nature of the salts existing in the juice. They are thus rendered softer, and more liable to become mouldy upon the surface. Others, especially such as contain much chlorophyll, harden by time, in consequence of the escape of their moisture, and it not unfrequently happens that small crystals of saline matter are formed in their substance; sodium chloride in small cubes is sometimes found in certain old extracts, having slowly crystallized as they hardened. John Attfield of London, has made a chemical examination of the crystals found in numerous extracts, and ascertained that in a large number they consisted of potassium chloride, and in a comparatively few of potassium nitrate. Potassium chloride was detected in the extracts of belladonna, hemlock, sarsaparilla (compound), colchicum seed, stramonium seed, and aconite; potassium nitrate in the extracts of belladonna, hyoscyamus, and lettuce; and sodium sulphate in extract of stramonium seed. (*P. J.*, March, 1862, p. 448.) The air, moreover, exercises an unfavorable chemical influence over the softer extracts, which are enfeebled, and ultimately become nearly inert, by the same changes which they undergo more rapidly in the liquid state at an elevated temperature. If an extract be dissolved in water, and the liquid be saturated with common salt or any other very soluble salt of difficult decomposition, the greater part of it will be precipitated, in consequence of the insolubility of this class of substances in saline solutions. The precipitate may be again dissolved in pure water.

Abstracts, which were official in the U. S. P., 1880, were not re-introduced in the U. S. P. (8th Rev.), as they did not come into general use; this is unfortunate, as they had many advantages, and are used in certain sections of the country. A description and a typical formula, with comments, will be found in the U. S. Dispensatory, 19th edition, p. 466.

Extracts, in order that they may keep well, should be placed in glazed earthenware, glass, or porcelain jars, and completely protected from the access of the air. This may be effected by covering their surface with a layer of melted wax, or with a piece of paper moistened with strong spirit, then closing the mouth of the vessel with a cork, spreading wax or rosin over this, and covering the whole with leather or a piece of bladder. The application of alcohol to the surface has a tendency to prevent mouldiness. Should the extract become too moist, it may be dried by means of a water bath; should it, on the contrary, be too dry, the proper consistence may be restored by softening it in the same manner and incorporating with it a little distilled water. Martin proposes to preserve extracts in a soft condition by surrounding the vessel containing the extract by another of larger diameter, which is furnished with a tight cover, the space between the two vessels being filled with crystallized sodium sulphate, which gradually parts with its water of crystallization and prevents the extract from becoming hard and dry.

When extracts which are too soft are subjected to a moderate temperature, fermentation may set in; E. Cocardas describes the various forms of "Penicillium-ferment" which are found in such extracts, and concludes that the ferment causes them to undergo changes similar to those effected by heat—*viz.*, the absorption of oxygen and the disengagement of carbon dioxide. (*P. J.*, 1886, p. 590.)

It is preferable to add a definite weight of the glycerin to the percolate. If it were added to the menstruum, owing to the variation in the yield of extracts from plants, some would be too soft, and at another time, in the case of a large yield of extract, the quantity of glycerin would be insignificant.

Extracts from recent plants should be prepared at the season when the plant is medicinally most active; a good rule is to prepare them once a year; but the demand for extracts from fresh drugs has declined rapidly of late, as it has been found that properly dried drugs yield extracts of uniform strength.

Powdered Extracts.—These extracts are largely superseding soft extracts for reasons given in preceding paragraphs; the difficulty of making them arises from the injurious in-

fluence of heat upon concentrated percolates of organic substances, but by the use of vacuum apparatus, suitable absorptive diluents and care, they should be made successfully.

Some extracts when powdered have a tendency to cohere. According to Geiseler, this may be obviated by the addition of sugar of milk or powdered licorice root, two or three parts of the former and one part of the latter to one of the extract being sufficient for the purpose. (*Ph. Cb.*, 1850, p. 238.) Mohr recommends the following plan of drying and preserving extracts. Take equal parts of powdered licorice-root and of the extract, rub them well together in a mortar, put the resulting paste into an earthen vessel with a flat bottom, place this in another of iron, a little deeper, containing calcium chloride thoroughly dried by heat insufficient to melt it; then enclose the whole with a cover fitted to the iron vessel, and allow them to stand for a day or more. When the mixture is quite dry, powder it, and add so much of the powdered root as to make the weight double that of the original extract. This process was substantially adopted in the German Pharmacopœia (1882). The old process of using dextrin as a diluent was found very objectionable, principally on account of the tendency of the extracts to reabsorb moisture. Four parts of extract are now mixed with three parts of finely powdered licorice-root, and dried in a porcelain dish at 40° to 50° C. (104°–122° F.) until the mixture ceases to lose weight. The mass is then rubbed to powder, and sufficient powdered licorice-root added to make the whole weigh eight parts, or double the weight of extract used. In our opinion, this method is not so good as that formerly adopted for abstracts. The German powdered extracts are always half the strength of the extracts, no relation whatever with the drug is established, and the variations in the yield of extract from different drugs have been repeatedly shown to be great. Kirchmann proposes exsiccated sodium sulphate as a diluent instead of dextrin, licorice-root, etc. (*Ph. Ztg.*, 1881, 116.) A. B. Lyons, of Detroit (1898), has introduced *scale extracts*. These do not, as a class, bear a definite relation to the drug; they are assayed, however, and acacia is used as a means of preserving their dry condition; they are easily pulverized, and are very convenient for dispensing.

The plan of incorporating a little glycerin with extracts has been recommended for such extracts as require it, 10 per cent. of glycerin being added to the liquid extract before evaporating to a pilular consistence. By its unchangeable liquid character, glycerin keeps the extract soft, so that it can be readily made into pills, and it also exercises a favorable influence through its chemical properties. The U. S. P. (8th Rev.) directs the use of glycerin for this purpose as follows: "When it is desired to preserve a solid extract (for instance, of Gentian, Taraxacum, etc.) in a plastic condition, suitable for making pills, or for other purposes, it is recommended that there be incorporated with it, after it has been evaporated to the proper consistence, and while it is still warm, 10 per cent. of its weight of glycerin." *U. S.*

Eight extracts were dismissed at the last revision of the U. S. Pharmacopœia, these were as follows: Aloes, digitalis, euonymus hæmatoxylon, krameria, leptandra, quassia, and scopola; five extracts were added as follows: Aconite, oxgall, gelsemium, hydrastis, viburnum prunifolium.

EXTRACTUM ACONITI. U. S.

EXTRACT OF ACONITE Ext. Aconit. [Powdered Extract of Aconite]

(ĕx-trăc'tŭm ăc-o-nī'tī)

"Extract of Aconite yields not less than 1.8 per cent. nor more than 2.2 per cent. of the ether-soluble alkaloids of aconite and, if assayed biologically, the minimum lethal dose should not be greater than 0.00001 Gm. for each gramme of body weight of guinea-pig. *One gramme* of the Extract represents about *four grammes* of aconite." *U. S.*

* "Aconite, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Tartaric Acid, *five grammes* [or 77 grains]; Purified Petroleum Benzin, Starch, dried at 100° C. (212° F.), Alcohol, each, *a sufficient quantity.* Dissolve the tartaric acid in *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol, moisten the drug with this solution and pack it in a cylindrical glass percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed very slowly, adding alcohol as required. Reserve the first *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of percolate and continue the percolation, until the second percolate measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] or until the drug is exhausted. Transfer this second percolate to a suitable apparatus and distil off the alcohol at as low a temperature as practicable, until a residue measuring about *one hundred mils* remains then add the reserved percolate and continue distillation until the residue in the still is of syrupy consistence. Transfer this syrupy residue to a flask, using a little warm alcohol to rinse the still, and adding the rinsing to the flask. When it has cooled, add *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of purified petroleum benzin and shake the mixture thoroughly for several minutes. Allow the liquids to separate and decant the benzin layer as closely as possible; add again to the residue *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of purified petroleum benzin, agitate and decant the benzin layer as before. Transfer the syrupy residue to a shallow evaporating dish, rinse the flask with *twenty mils* [or 325 minims] of warm alcohol, adding the rins-

ings to the residue in the dish, and then incorporate *fifty grammes* [or 1 ounce av., 334 grains] of the thoroughly dried starch. Evaporate the mixture by a very gentle heat on a water bath, frequently stirring, and, when the mass has become thick, spread it on glass plates and continue the drying in an air bath at a temperature not exceeding 70° C. (158° F.) until thoroughly dry. Reduce the product to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the powder and add to this enough of the dried starch to make the finished Extract contain 2 per cent. of the ether-soluble alkaloids of aconite. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly.

"**Assay.**—Introduce 3 Gm. of Extract of Aconite into a 250 mil flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 mils of ether and 2 mils of ammonia water, shake the mixture vigorously every few minutes during a half hour, and when the dregs have settled decant 100 mils of the clear liquid, representing *two grammes* of the Extract. Proceed as directed under *Belladonnæ Radix*, page 222, twelfth line of the Assay, beginning with the word "Filter," modifying the process there given by using ether instead of chloroform for the final shaking out of the alkaloids.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 64.539 milligrammes of the ether-soluble alkaloids of aconite." *U. S.*

For a biological method of assaying Extract of Aconite, see *Aconitum.*

This extract is an undesirable addition to the U. S. P. IX and requires the utmost care in its preparation, for notwithstanding the addition of both a chemical and biological assay it is often variable in strength as found in commerce.

Dose, one-eighth to one-fourth grain (0.008–0.015 Gm.).

EXTRACTUM ALOES. Br.

EXTRACT OF ALOES

(ĕx-trăc'tŭm ăl'ō-ēs)

Extrait d'Aloès, *Fr.*; Extractum Aloës, *P. G.*; Aloeextract, *G.*; Estratto di aloe acquoso, *It.*

"Aloes, in small fragments, 1000 *grammes;* Distilled Water, boiling, 10,000 *millilitres.* Add the Aloes to the Distilled Water and stir well until they are thoroughly mixed; set aside the mixture for twenty-four hours; decant; strain; evaporate the strained liquid to dryness at a temperature not exceeding 60° C. (140° F.)." *Br.*

The object of this preparation is to afford an aloes purified from mechanical impurities. The process is based upon the British formulas for extracts of Barbados aloes and Socotrine aloes, formerly official. With an official purified aloes, the necessity for this preparation is not obvious. The U. S. P. IX dismissed Extract of Aloes and Aloe Purificata, but added tests for Aloes which exclude inorganic impurities, gum, etc. See *Aloe*, page 115. A powdered extract is official in the N. F. IV. (See Part III.) An extract made with cold distilled water was formerly official in the German Pharmacopœia, as was also the vitriolated extract, "*Extractum Aloes Acido Sulfurico Correctum,*" made by suspending eight parts of extract of aloes in thirty-two parts of distilled water, adding drop by drop one part of pure sulphuric acid, and evaporating in a porcelain vessel to dryness.

Dose, one to five grains (0.06–0.3 Gm.).

EXTRACTUM BELLADONNÆ FOLIORUM. U. S. (Br.)

EXTRACT OF BELLADONNA LEAVES Ext. Bellad. Fol. [Extractum Belladonnæ Foliorum Alcoholicum, Pharm. 1890]

(ĕx-trăc'tŭm bĕl-lą-dŏn'næ fō-lĭ-ō'rŭm)

"Extract of Belladonna Leaves yields not less than 1.18 per cent. nor more than 1.32 per cent. of the alkaloids of belladonna leaves. *One gramme* of the Extract represents about *four grammes* of belladonna leaves." *U. S.* "Dry Extract of Belladonna contains in 100 grammes 1 gramme of the alkaloids of Belladonna Leaves." *Br.*

Extractum Belladonnæ Siccum, *Br.*, Dry Extract of Belladonna; Extractum Belladonnæ Alcoholicum; Extractum Belladonnæ; Extrait de Belladone (Racine), *Fr. Cod.;* Spirituöses Tollkirschenextrakt, *G.;* Estratto di belladonna idroalcoolico, *It.;* Extracto alcoholico de belladona, *Sp.*

The alcoholic extracts of belladonna of the U. S. P., 1880 and 1890, were made from the leaves, in deference to a prejudice which seems to have a strong following. The British Pharmacopœia introduced in the 1885 revision for the first time an alcoholic extract of belladonna, but it differed from the U. S. extract in being made from the root instead of the leaves. The British alcoholic (root) extract (1898) was 66 per cent. weaker than the Br. Pharm., 1885, extract; it now contains 1 per cent. of the alkaloids of belladonna leaves, and is called dry extract of belladonna. The green extract of belladonna made from the juice of fresh leaves and branches is no longer official. (See *U. S. D.*, 19th edition, p. 471.) The absence of chlorophyll in an extract made from the root would cause ointments, cerates, plasters, etc., made from it to be deficient in the characteristic green color so much prized, but there can be no question of the greater uniformity in strength of the root.

The U. S. P. IX introduced this extract in two forms, Pilular Extract and Powdered Extract, so that the pharmacist might select the form that was best suited for dispensing. The

pilular extract is used officially in the ointment. Both forms of the extract, however, are of the same strength.

Pilular Extract of Belladonna Leaves

* "Belladonna Leaves, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glucose, Alcohol, Water, each, *a sufficient quantity*. Moisten the powder with sufficient of a mixture of *three volumes* of alcohol and *one volume* of water and pack it firmly in a cylindrical percolator, then add enough menstruum, using the same proportion of alcohol and water as before, to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum of the same strength, until the percolate measures *three thousand mils* [or 101 fluidounces, 212 minims], or until the belladonna leaves are exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue with frequent stirring, at a temperature not exceeding 70° C. (158° F.), to a pilular consistence. Mix the mass thoroughly and weigh it. Assay a portion of this extract, as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the mass, and to this add enough glucose to make the finished Extract contain 1.25 per cent. of the alkaloids of belladonna leaves. Mix thoroughly.

"**Assay.**—Dissolve 2 Gm. of Pilular Extract of Belladonna Leaves in 10 mils of diluted alcohol, transfer the solution to a separator and wash the vessel in which the extract was dissolved with 2 mils of ammonia water previously diluted with 10 mils of distilled water, in divided portions, adding the rinsings to the separator, then proceed as directed under *Fluidextractum Belladonnæ Radicis*, page 486, fourth line of the Assay, beginning with the word "Completely," modifying the process there given by treating the residue twice with 5 mils of ether and evaporating to dryness each time before titration.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the alkaloids of belladonna leaves.

Powdered Extract of Belladonna Leaves

* "Belladonna Leaves, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Magnesium Oxide, *twenty grammes* [or 309 grains]; Starch, dried at 100° C. (212° F.), Alcohol, each, *a sufficient quantity*. Moisten the drug with sufficient alcohol and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed very slowly, adding alcohol as required. Reserve the first *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of percolate and continue the percolation until the second percolate measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] or until the drug is exhausted. Transfer the second percolate to a suitable apparatus and distil off the alcohol at as low a temperature as practicable, until a residue measuring about *one hundred mils* [or 3 fluidounces, 183 minims] remains, then add the reserved percolate and continue distillation until the residue in the still is of syrupy consistence. Transfer this syrupy residue to a shallow evaporating dish, rinse the flask or still with a small quantity of warm alcohol, adding the rinsing to the residue in the dish. Evaporate this extract to a pilular consistence, at a temperature not exceeding 70° C. (158° F.), then add *fifty grammes* [or 1 ounce av., 334 grains] of the dried starch and continue the heating, with frequent stirring, until the mass is nearly dry. Now add the magnesium oxide, thoroughly incorporate it and set the product aside in a current of warm air, until thoroughly dry. Reduce the product to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the powder and add to this enough of the dried starch to make the finished Extract contain 1.25 per cent. of the alkaloids of belladonna leaves. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly.

"**Assay.**—Introduce 3 Gm. of Powdered Extract of Belladonna Leaves into a 250 mil flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 mils of a mixture of chloroform, 1 volume, and ether, 2 volumes, followed by 5 mils of ammonia water. Shake the mixture vigorously every ten minutes during a half hour and when the dregs have settled decant 100 mils of the clear liquid, representing *two grammes* of the Extract; now proceed as directed under *Belladonnæ Radix*, eleventh line of the Assay, beginning with the word "Filter," modifying the process there given by treating the residue twice with ether, and evaporating to dryness each time before titration.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the alkaloids of belladonna leaves." *U. S.*

"Belladonna Leaves, in No. 40 powder, Alcohol (70 per cent.), of each, *a sufficient quantity*. Reduce ten grammes of the Belladonna Leaves to No. 60 powder and determine the proportion of alkaloids present by the process described under 'Belladonnæ Folia.' Moisten one thousand grammes of the Belladonna Leaves with two hundred and fifty millilitres of the Alcohol, pack firmly in a percolator and percolate with more of the Alcohol until four thousand millilitres of percolate have been obtained. Determine the proportion of total solids in the

percolate by evaporating twenty millilitres, drying the residue at 80° C. (176° F.), and weighing. Determine also the proportion of alkaloids in the percolate, by the process described under 'Tinctura Belladonnæ,' employing forty millilitres of the percolate in the place of one hundred millilitres of the Tincture. Having thus determined the proportion of total solids and of alkaloids in the percolate, calculate the amount of each the remainder of the percolate will yield, and also the amount of the powdered Belladonna Leaves, the alkaloidal strength of which has also been determined, that must be added to afford a dry extract containing 1 per cent. of alkaloids. Add to the percolate a somewhat smaller amount of the powdered Leaves than calculation has shown to be necessary, recover the alcohol by distillation, and dry the residue in a shallow, flat, tared dish, first on a water-bath, and finally in a current of air at 60° to 80° C. (140°–176° F.). Weigh the dish with its contents, calculate the additional amount of powdered Leaves that will be necessary, add this to the product of evaporation, transfer the whole to a dry, slightly warmed mortar and triturate carefully until thoroughly mixed. Pass the powdered Extract through a No. 20 sieve, transfer to a bottle which can be securely closed, and preserve in a cool dry place. Slightly moisten 5 grammes of the Extract with a mixture of 1 volume of *acetic acid* and 9 volumes of *alcohol* (70 per cent.), pack in a small percolator and percolate with the same menstruum, if necessary under increased air-pressure, until 50 millilitres of percolate have been collected. Then proceed as described under 'Tinctura Belladonnæ,' using 50 millilitres of percolate in the place of 100 millilitres of the Tincture. Examined by the foregoing process, Dry Extract of Belladonna is found to contain in 100 grammes 1 gramme of the alkaloids of Belladonna Leaves. *Limit of error* 0.05 gramme in excess or defect. This Dry Extract contains 1 per cent. of the alkaloids of Belladonna Leaves." *Br.*

Uses.—There is no physiological difference between the pilular and powdered extracts of belladonna. The former may be used in the preparation of pills or ointments the latter wherever the action of belladonna is wished in the form of a powder or compressed tablet. For the conditions in which these extracts are useful, see under *Atropina*.

Dose, internally, from one-sixth to one-third of a grain (0.010–0.021 Gm.).

Off. Prep.—Emplastrum Belladonnæ, *U. S., Br.;* Suppositoria Belladonnæ, *Br.;* Unguentum Belladonnæ, *U. S.;* Pilulæ Aloes et Podophylli Compositæ (from Pilular Extract), *N. EXTRACTUM CANNABIS. U. S. (Br.)

EXTRACT OF CANNABIS Ext. Cannab. [Extractum Cannabis Indicæ, U. S. P. VIII]

(ĕx-trăc'tŭm căn'nȧ-bĭs ĭn'dĭ-cæ)

"Extract of Cannabis, when assayed biologically, produces incoördination when administered to dogs in a dose of not more than 0.004 Gm. of Extract per kilogramme of body weight." *U. S.*

Extractum Cannabis Indicæ, *Br.;* Extract of Indian Hemp: *Br.;* Extrait de Chanvre de l'Inde, *Fr. Cod.;* Indischer Hanfextrakt, *G.*

* "Cannabis, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*. Moisten the powder with sufficient alcohol, pack it firmly in a cylindrical percolator and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol, until the drug is exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue with frequent stirring, at a temperature not exceeding 70° C. (158° F.), to a pilular consistence. Mix the mass thoroughly and weigh it. Assay a portion of this extract, and from the result thus obtained adjust the weight of the finished Extract, by the addition of glucose, to conform to the required biological standard.

"**Assay.**—Proceed as directed under Biological Assays." *U. S.* (See under *Cannabis* and Part III.)

"Exhaust Indian Hemp, in coarse powder, with Alcohol (90 per cent.) by the *percolation process;* recover the alcohol by distillation, and evaporate the residue to a soft extract." *Br.*

The continuation in the Br. Pharm. of the name of Indian Hemp is unfortunate because of the possibility of its being mistaken for the root of *Apocynum cannabinum*, which is also called Indian Hemp. Several mistakes have occurred through this unfortunate confusion of nomenclature.

Although there is some difference in the details of the two processes, the preparations of the U. S. and Br. Pharmacopœias are practically identical. The U. S. P. IX provides a biological test. (See Part III.)

Great care is necessary in the manufacture of this extract not only in the selection of the crude drug, but also there is reason to believe that excessive heat in evaporating may have an injurious effect on the quality of the preparation. The only means of ascertaining its activity is by means of the biological test. (See p. 279.) The preparation varies exceedingly in strength, so that it is wisest to begin with a small dose, one-quarter of a grain (0.016 Gm.), and rapidly increase the amount given until some effect is produced.

Dose, one-fourth to three-fourths of a grain (0.015–0.045 Gm.).

Off. Prep.—Tinctura Cannabis Indicæ, *Br.;* Mistura Chlorali et Potassii Bromidi Composita, *N. F.*

EXTRACTUM CASCARÆ SAGRADÆ. U. S. (Br.)

EXTRACT OF CASCARA SAGRADA Ext. Casc. Sagr. [Extractum Rhamni Purshianæ, U. S. VIII, Powdered Extract of Cascara Sagrada]

(ĕx-trăc'tŭm căs-căr'æ să-grăd'æ)

"*One gramme* of the Extract represents *three grammes* of cascara sagrada." *U. S.*

Extractum Cascaræ Sagradæ Siccum, *Br.;* Dry Extract of Cascara Sagrada; Extrait de Cascara Sagrada, *Fr. Cod.;* Cascara Sagrada-Extrakt, Amerikanisches Faulbaumrindenextrakt, *G.;* Extracto alcoholico de cascara sagrada, *Sp.*

* "Cascara Sagrada, in No. 20 powder, *nine hundred grammes* [or 31 ounces av., 327 grains]; Magnesium Oxide, *twenty-five grammes* [or 386 grains]; Starch, dried at 100° C. (212° F.), Boiling Water, each, *a sufficient quantity,* to make *three hundred grammes* [or 10 ounces av., 255 grains]. Mix the cascara sagrada with *four thousand mils* [or 135 fluidounces, 122 minims] of boiling water and macerate the mixture during three hours. Then transfer it to a metallic percolator, allow it to drain and pour on boiling water until the percolate measures *five thousand mils* [or 169 fluidounces, 33 minims], or the drug is exhausted. Evaporate the percolate to dryness on a water bath or steam bath, reduce the extract to a fine powder, weigh it, add the magnesium oxide and enough of the dried starch to make the product weigh *three hundred grammes* [or 10 ounces av., 255 grains]. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

"Exhaust Cascara Sagrada, in No. 20 powder, with Distilled Water by the *percolation process;* evaporate the percolate to dryness on a water-bath." *Br.*

This powdered extract was made official in the U. S. P. VIII for the first time; 1 part of the extract represented 4 parts of the drug; in the U. S. P. IX 1 part represents 3 parts of the drug.

The British preparation (1914) is a dry extract. It well represents the virtues of the bark, and furnishes a good means of administering this purgative in pilular form.

Dose, from two to eight grains (0.13–0.5 Gm.).

Off. Prep.—Pilulæ Aloini, Strychninæ et Belladonnæ Compositæ, *N. F.*

EXTRACTUM CIMICIFUGÆ. U. S.

EXTRACT OF CIMICIFUGA Ext. Cimicif. [Powdered Extract of Cimicifuga]

(ĕx-trăc'tŭm cĭm-ĭ-cĭf'ŭ-gæ)

"*One gramme* of the Extract represents *four grammes* of cimicifuga." *U. S.*

Extract of Black Cohosh; Extrait d'Actée à grappes, *Fr.;* Cimicifugaextrakt, *G.*

* "Cimicifuga, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Starch, dried at 100° C. (212° F.), each, *a sufficient quantity,* to make *two hundred and fifty grammes* [or 8 ounces av., 358 grains]. Moisten the drug with sufficient alcohol, pack it in a cylindrical percolator, and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding alcohol as required until the drug is exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue to dryness, with frequent stirring, at a temperature not exceeding 70° C. (158° F.). Weigh the residue and add sufficient of the dried starch to make the product weigh *two hundred and fifty grammes* [or 8 ounces av., 358 grains]. Reduce the mixture to a fine powder, mix thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

In the U. S. P. VIII this extract was made from the fluidextract, but the U. S. P. IX gives a process. This extract was introduced for the reason that although the fluidextract and tincture represent the virtues of cimicifuga, the alcohol present in both may be therapeutically contra-indicated, and the exceedingly disagreeable taste of the drug is entirely masked if the extract be prescribed in the form of a pill, with proper additions, such as extract of licorice, or if the pill be coated or enclosed in a capsule. It is used in the treatment of *chorea.*

Dose, of the extract, from three to ten grains (0.2–0.65 Gm.).

EXTRACTUM COLCHICI CORMI. U. S. (Br.)

EXTRACT OF COLCHICUM CORM Ext. Colch. Corm. [Powdered Extract of Colchicum Corm]

(ĕx-trăc'tŭm cŏl'chĭ-cī cŏr'mī)

"Extract of Colchicum Corm yields not less than 1.25 per cent. nor more than 1.55 per cent. of colchicine. *One gramme* of the Extract represents about *four grammes* of colchicum corm." *U. S.*

Extractum Colchici, *Br.;* Extractum Colchici Radicis, *U. S.,* 1890; Extrait de Colchique acetique, *Fr.;* Zeitlosen Essigextrakt, *G.*

* "Colchicum Corm, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Purified Petroleum Benzin, Starch, dried at 100° C. (212° F.), each, *a sufficient quantity.* Moisten the drug with sufficient alcohol, pack it in a cylindrical percolator and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then

allow the percolation to proceed slowly, adding alcohol as required, until the percolate measures *two thousand mils* or until the drug is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable until a residue measuring about *one hundred and fifty mils* [or 5 fluidounces, 35 minims] remains in the still. Transfer this residue to a flask, using a little warm alcohol to rinse the still, and add the rinsings to the flask. When it has cooled, add *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of purified petroleum benzin and shake the mixture thoroughly for several minutes. Allow the liquids to separate and decant the benzin layer as closely as possible; again add to the residue *one hundred and fifty mils* [or 5 fluidounces, 35 minims] of purified petroleum benzin, agitate and decant the benzin layer as before, repeat the washing with *one hundred mils* [or 3 fluidounces, 183 minims] of purified petroleum benzin and reject the benzin washings. Transfer the residue to a shallow evaporating dish, rinse the flask with a little warm alcohol, adding the rinsings to the residue in the dish, and evaporate it on a water bath to a thick extract. To this add *fifty grammes* [or 1 ounce av., 334 grains] of the dried starch, mix well, spread the mixture on glass plates and continue the drying in an air bath at a temperature not exceeding 70° C. (158° F.) until thoroughly dry. Reduce the product to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloid in the remainder of the powder and add to this enough of the dried starch to make the finished Extract contain 1.4 per cent. of colchicine. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small wide-mouthed bottles and stopper them tightly." *U. S.*

"Crush fresh Colchicum Corms, deprived of their coats; press out the juice; allow the feculence to subside, decant; heat the clear liquid to 100° C. (212° F.); strain through flannel, and evaporate at a temperature not exceeding 70° C. (158° F.) to a soft extract." *Br.*

The U. S. VIII extract was an acetic extract of the corm, but in the U. S. P. IX process the acetic acid was omitted. The British extract is made by evaporating the juice of fresh corms.

In Great Britain a preparation called *preserved juice of colchicum* is given in the dose of five minims (0.3 mil) or more. It is made by expressing the fresh corm, allowing the juice to stand for forty-eight hours that the starchy matter may subside, then adding one-fourth of its bulk of alcohol, allowing it again to stand for a short period, and ultimately filtering.

"**Assay.**—Proceed as directed under *Colchici Semen*, page 371, modifying the process there given by using 6 Gm. of the Extract of Colchicum Corm instead of 15 Gm. of colchicum seed. The final weight will be the amount of colchicine from *two grammes* of Extract of Colchicum Corm." *U. S.*

As the fresh colchicum corm is rarely to be had in this country, the U. S. Pharmacopœia employs the dried corm; its process, if properly conducted, will afford a very efficient extract. In preparing this extract according to the British process, by expression from the recent corm, there will be experienced some inconveniences, which would seem to render the U. S. process under all circumstances preferable. (*P. J.*, xiii, 62.) The acetic extract of colchicum made from fresh corms was abandoned by the Br. Ph., 1898, and by the U. S. P. IX, but the acetic acid menstruum is a good solvent for colchicine.

Dose, from one-fourth to one grain (0.016–0.065 Gm.).

EXTRACTUM COLOCYNTHIDIS. U. S.

EXTRACT OF COLOCYNTH Ext. Colocynth. [Powdered Extract of Colocynth]

(ĕx-trăc'tŭm cŏl-o-cŷn'thĭ-dĭs)

"*One gramme* of the Extract represents *four grammes* of colocynth." *U. S.*

Extractum Colocynthidis Alcoholicum; Extrait de Coloquinte, *Fr. Cod.*; Extractum Colocynthidis, *P. G.*; Koloquintenextrakt, *G.*; Estratto di coloquintide idroalcoolico, *It.*

* "Colocynth, in No. 20 powder, *one thousand grammes* (freed from the seeds) [or 35 ounces av., 120 grains]; Diluted Alcohol, Starch, dried at 100° C. (212° F.) each, *a sufficient quantity*, to make *two hundred and fifty grammes* [or 8 ounces av., 358 grains]. Moisten the drug with *two thousand mils* [or 67 fluidounces, 301 minims] of diluted alcohol and macerate it in a closed vessel for twenty-four hours, then transfer the moist drug to a cylindrical percolator, shake it down evenly without packing, and gradually pour diluted alcohol upon it, allowing the percolation to proceed slowly, until the percolate measures *five thousand mils* [or 169 fluidounces, 33 minims]. Recover the alcohol from the percolate by distillation and evaporate the residue to dryness on a water bath or steam bath. Reduce the extract to a fine powder, weigh it, and add sufficient of the dried starch to make the product weigh *two hundred and fifty grammes* [or 8 ounces av., 358 grains]. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

The colocynth should always be deprived of its seeds, following the directions of the U. S. Pharmacopœia, before being submitted to the action of the menstruum. Boiling water extracts such a large amount of pectin and mucilage from colocynth that either the decoction or the hot infusion gelatinizes on cooling, and the extract made by means of it is therefore loaded with inert matter, and, besides, is liable to become mouldy, or so tough and hard as to resist trituration and formation into pills. Hence many years ago the London College, following

in this respect the old French Codex, directed, in the last edition of its Pharmacopœia, maceration with cold water; but diluted alcohol has been found to be a much better menstruum, and has accordingly been adopted in the U. S. Pharmacopœia process, while in the British Pharmacopœia the simple extract has been discarded altogether. The chief, if not exclusive, use of the alcoholic extract is in the preparation of the compound extract.

This preparation should never be substituted for an extract prepared with a menstruum containing a larger percentage of water, because the water extracts a large quantity of mucilaginous and inert matter. Commercial extract of colocynth may be often found in the market made with an aqueous menstruum.

Dose, one-half grain (0.032 Gm.).

Off. Prep.—Extractum Colocynthidis Compositum, *U. S.;* Pilulæ Colocynthidis Compositæ, *N. F.;* Pilulæ Colocynthidis et Hyoscyami, *N. F.*

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. U. S., Br.

COMPOUND EXTRACT OF COLOCYNTH Ext. Colocynth. Co. [Powdered Compound Extract of Colocynth]

(ĕx-trăc'tŭm cŏl-o-cŷn'thĭ-dĭs cŏm-pŏs'ĭ-tŭm)

Extrait de Coloquinte composé, *Fr.;* Zusammengesetztes Koloquintenextrakt, *G.*

• "Extract of Colocynth, *one hundred and sixty grammes* [or 5 ounces av., 282 grains]; Aloes, *five hundred grammes* [or 17 ounces av., 279 grains]; Cardamom Seed, in No. 60 powder, *fifty grammes* [or 1 ounce av., 334 grains]; Resin of Scammony, in No. 60 powder, *one hundred and forty grammes* [or 4 ounces av., 411 grains]; Soap, dried and in powder, *one hundred and fifty grammes* [or 5 ounces av., 127 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Triturate the ingredients until the product is reduced to a No. 60 powder. Pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

"Colocynth Pulp, 150 *grammes;* Extract of Aloes, 300 *grammes;* Scammony Resin, 100 *grammes;* Curd Soap, in powder, 75 *grammes;* Cardamom Seeds, in powder, 25 *grammes;* Alcohol (60 per cent.), 4000 *millilitres*. Macerate the Colocynth Pulp in the Alcohol for four days; press out the tincture; recover the alcohol by distillation; evaporate to dryness; add the Extract of Aloes, Scammony Resin, and powdered Cardamom Seeds; powder; mix the powder with the Curd Soap." *Br.*

The Br. Pharm. (1914) directs Extract of Aloes instead of Barbados Aloes, and decreased the proportion of soap from four to three ounces. The object of the soap is to improve the consistence of the mass, which, when hardened by time, it renders more soluble in the gastric juices. It may possibly also serve the purpose of modifying the action of the aloes. In the U. S. process the extract is in the form of powder, which is very convenient for admixture with other substances; while if given uncombined, it may be readily made into pills by suitable additions. The alternative of using the scammony or its resin, in the first British formula, which appeared to us very objectionable, has been abandoned in the present edition, and the resin only directed. The plan of having the powders simply mixed was liable to the objection that the mixture was not likely to be so thoroughly effected as to obtain a uniform result, and hence the U. S. Pharm., 1880, adopted Squibb's suggestion, to melt together all the ingredients unpowdered, except the cardamom, add a little alcohol, and, when the mixture is thoroughly made, to stir in the powdered aromatic, and finally to reduce the whole to a fine powder. The U. S. P. IX, however, relies upon trituration as an assurance of thorough commingling.

This extract is an energetic and safe cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, jalap, calomel, etc., with one or more of which it is often united in prescription.

Dose, as a laxative, one to two grains (0.065–0.13 Gm.); as a purgative, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Pilulæ Catharticæ Compositæ, *U. S.;* Pilulæ Catharticæ Vegetabiles, *N. F.;* Pilulæ Antidyspepticæ, *N. F.;* Pilulæ Colocynthidis et Podophylli, *N. F.;* Pilulæ Laxativæ Post Partum, *N. F.*

EXTRACTUM ERGOTÆ. U. S., Br.

EXTRACT OF ERGOT Ext. Ergot.

(ĕx-trăc'tŭm ẹr'gọ-tæ)

Extractum Hæmostaticum; Ergotin, *Br.* (1898); Extrait de Seigle Ergoté, *Fr. Cod.;* Extractum Secalis cornuti, *P. G.;* Mutterkornextrakt, *G.;* Estratto di segala cornutta, *It.*

• "Ergot, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Hydrochloric Acid, *ten mils* [or 162 minims]; Purified Petroleum Benzin, Alcohol, Water, each, *a sufficient quantity*. Pack the ergot in a percolator and slowly percolate it with purified petroleum benzin until a few drops of the percolate, evaporated on filter paper leave no greasy stain. Reject the benzin percolate remove the ergot from the percolator and dry it by exposure to the air. Mix *eight hundred and fifty mils* [or 28 fluidounces, 356 minims] of alcohol with *one hundred and fifty mils* [or 5 fluidounces, 35 minims] of water add the hydrochloric acid to *four hundred mils* [or 13 fluidounces, 252 minims] of this mixture, and moisten the ergot with the acid mixture. Pack it in a cylindrical percolator and macerate for six hours, then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the

lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportion of alcohol and water as before, until the drug is exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue with frequent stirring, at a temperature not exceeding 70° C. (158° F.), to a pilular consistence." *U. S.*

"Ergot, crushed, 1000 *grammes;* Distilled Water, 7500 *millilitres;* Alcohol (90 per cent.), 650 *millilitres.* Macerate the Ergot with *five thousand millilitres* of the Distilled Water for twelve hours; strain; repeat the maceration with the remainder of the Distilled Water; strain; press; evaporate the mixed liquids to *five hundred millilitres;* add the Alcohol; set aside for three days, stirring occasionally; filter; evaporate the filtrate to a soft extract." *Br.*

The menstruum for this extract in the U. S. P. IX is a great improvement over the previous revision in that the percentage of alcohol is increased. The Br. extract is inferior because it is an aqueous extract. Great care is needed in the evaporation as excessive heat destroys the activity of ergot. Pearson (*J. A. Ph. A.*, 1913, ii, 1453) found that after heating for thirty minutes on the water bath fluidextract of ergot was practically inert.

Dose, from five to fifteen grains (0.32 to 1.0 Gm.).

Off. Prep.—Injectio Ergotæ Hypodermica, *Br.*

EXTRACTUM EUONYMI. Br.

EXTRACT OF EUONYMUS

(ĕx-trăc'tŭm eū-ŏn'y-mī)

Dry Extract of Euonymus; Extract of Wahoo; Extrait d'Evonymus atropurpureus, *Fr. Cod.;* Extrait de Fusain Américaine, *Fr.;* Spindelbaumextrakt, Spillbaumrindenextrakt, *G.*

"Exhaust Euonymus Bark in No. 20 powder with Alcohol (45 per cent.) by the *percolation process.* Evaporate the percolate and thoroughly dry the residue. Powder the product as far as possible and mix it with one-fourth of its weight of Calcium Phosphate, continuing the drying and powdering until a sufficiently dry preparation is obtained; transfer this to a well-closed bottle." *Br.*

This extract was not admitted to the U. S. P. IX, but was retained in the Br. Pharm. (1914) and introduced into the National Formulary IV (see Part III) which directs the percolation of euonymus in No. 40 powder with alcohol 4 volumes and water 1 volume. The percolate is evaporated or distilled and the residue dried and mixed with dried starch so that .1 Gm. of the extract represents 4 Gm. of euonymus. On account of the reports of physicians of cumulative effects the following note was inserted: "CAUTION—It has been stated that the absorption of Euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient." *N. F. IV.* Dry and powdered extract of euonymus is frequently but erroneously termed *"euonymin."*

Dose, one to three grains (0.065 to 0.2 Gm.).

EXTRACTUM FELLIS BOVIS. U. S. (Br.)

EXTRACT OF OXGALL. Ext. Fel. Bov. [Powdered Extract of Oxgall]

(ĕx-trăc'tŭm fĕl'lĭs bōv'ĭs)

"*One gramme* of the Extract represents *eight grammes* of oxgall." U. S.

Fel Bovinum Purificatum, *Br.;* Purified Ox Bile; Fel Tauri Depuratum; Extractum Fellis Bovini; Extrait de Fiel de Bœuf, *Fr. Cod.;* Gereinigte Ochsengalle (Rindsgalle), *G.;* Bile cristallizzata di platner, *It.;* Hiel de toro preparada, *Sp.*

* "Oxgall, *eight hundred grammes* [or 28 ounces av., 96 grains]; Alcohol, *fifteen hundred mils* [or 50 fluidounces, 5 fluidrachms, 45 minims]; Starch, dried at 100° C. (212° F.), *a sufficient quantity,* to make *one hundred grammes* [or 5 ounces av., 231 grains]. Add *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of alcohol slowly and with agitation to the oxgall contained in a bottle of sufficient size. Allow the mixture to stand for two days and then decant the liquid portion. Wash the residue in the bottle with an additional *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol, decant the liquid portion, mix it with the liquid first separated and filter the mixture. Recover the alcohol from the filtrate by distillation, transfer the residue to a shallow dish and evaporate it to a thick extract at a temperature between 75° and 80° C. (167° and 176° F.). Spread this extract on glass plates and continue the drying by exposure to warm air, at a temperature not exceeding 70° C. (158° F.), until thoroughly dry. Reduce the extract to a fine powder, weigh it and add sufficient of the dried starch to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

"Evaporate five hundred *millilitres* of fresh ox bile to one-fourth of its volume; shake this liquid with twice its volume of Alcohol (90 per cent.); set the mixture aside until the solid matter has subsided; decant the clear solution, and filter the remainder, washing the filter and contents with a little more Alcohol (90 per cent.). Distil off most of the alcohol from the mixed liquids, and evaporate the residue in a porcelain dish, on a water-bath, to the consistence of a firm extract." *Br.*

The object of this preparation is to furnish purified concentrated Oxgall in a condition in which it can be satisfactorily prescribed for internal administration. The addition of alcohol

to the concentrated liquid is made for the purpose of separating albuminous matter.

Properties.—"A yellowish-green hygroscopic substance, having a taste partly sweet and partly bitter, soluble in *water* and in *alcohol* (90 per cent.). 1 millilitre of an aqueous solution (1 in 100) in which 0.1 gramme of *refined sugar* has been dissolved, gradually acquires a deep violet color when mixed with 10 millilitres of *syrupy phosphoric acid* and heated in a water-bath. Its aqueous solution on the addition of twice its volume of *alcohol* (90 per cent.) gives no precipitate (absence of unpurified ox bile)." *Br.*

Refined oxgall, much used by painters, is prepared, according to Gray, in the following manner. Take of "fresh oxgall, one pint; boil, skim, and add one ounce of alum, and keep it on the fire for some time; to another pint, add one ounce of common salt in the same manner; keep them bottled up for three months; then decant off the clear; mix them in an equal proportion; a thick yellow coagulum is immediately formed, leaving the refined gall clear and colorless."

This extract replaces in the U. S. P. IX the *Fel Bovis Purificatum* of the former revision over which it has the advantage of being more concentrated. The British title is yet retained as Purified Ox Bile. It represents practically a mixture of sodium glycocholate and sodium taurocholate contaminated with traces of fatty and soapy matters. (See *Fel Bovis.*) The directions to add starch in sufficient quantity in this extract is unfortunate. The therapeutic activity of bile resides in its solid matters and as the proportion of these varies greatly it is manifest that the extract should be standardized, not as it is at present, to represent a certain amount of fresh bile, but to represent a proportion of dried bile, *i.e.,* of the biliary solids.

Uses.—By the ancients bile was a very highly esteemed remedy and was used in a great variety of conditions. It, however, fell into desuetude and for many years was rarely employed. Recently it has again come largely into favor but for a very different class of disorders. Its most frequent use to-day is to replace or augment the hepatic secretions when these for any reason are lacking. While the exact rôle that the bile plays in the intestinal tract is not clearly understood, it is well established that it plays an important part in digestion, especially of the fatty foods.

When introduced into the circulation bile has a depressant effect upon the heart muscle leading to a reduction in the blood pressure and slowing of the pulse. Whether or not the slowing of the pulse is partly indicative of inhibitory stimulation is at present under dispute, but it seems well established that after large doses, at least, the slowing of the pulse is the result of a direct action upon the heart muscle. According to Meltzer and Salant (*J. Ex. M.,* viii) there are present in the bile both an excito-motor and depresso-motor principle. Bile has long been recognized as the most powerful stimulant to the secretory activity of the liver which we possess, but according to Shaffer (*A. J. Phys.,* 1907, xvii, p. 389) this is not indicative of a true excitation of the hepatic cells but is simply that, after its injection, the blood contains the preformed material for excretion and that the increase in the output of the bile solids does not exceed the dose which was injected. The presence of bile in the intestinal tract has by some been held to diminish the multiplication of bacteria, but there is no convincing evidence of such an action. It increases peristaltic movements in the large intestines but appears to diminish those of the upper bowel.

Oxgall has been found useful in a variety of conditions in which there is a diminution in the amount of bile in the intestinal tract, as for instance in *catarrhal cholangitis,* and *hepatic torpor.* In *gall stones* while it may improve the digestion by offering a necessary ferment there is no sufficient reason to believe that it will aid the solution of the stones. It is also a valuable agent in the treatment of certain forms of *chronic constipation,* not solely because of its own action in increasing the peristalsis of the colon, but because its presence in the intestines is essential for the action of many of the cathartics. Cholesterin, which is one of the ingredients of bile, has the power of neutralizing certain poisons such as tetanotoxin, sapotoxin, and snake venom, and may perhaps prove clinically useful for this purpose. It should be noted, however, that as cholesterin is scarcely soluble in cold alcohol, the extract will contain not more than traces of it.

The daily amount of bile secreted by an ordinary man varies between two hundred and four hundred mils (6.7–13.3 fluidounces), containing from 1 to 3 per cent. of solids. If there is a marked reduction in the secretion of bile it is evident that the pharmacopœial dose is far too small to have any effect. Because of a supposed injurious action upon gastric digestion various recommendations have been made for administering bile in the form that it will pass through the stomach; among these may be mentioned the use of keratin coated or salol coated pills, and by mixing with spermaceti. We think, however, that the liability of disturbance of the stomach by this agent has been over-estimated.

Among the proprietary preparations of bile may be mentioned: *bilein,* which is marketed in pills ranging from one-twelfth to one-fourth of a grain (0.005–0.016 Gm.); *cholalin,* a yellow powder, dose one-fourth to one-half grain (0.016–0.032 Gm.); *glycotauro,* dose five to ten grains (0.32–0.65 Gm.); *ovogall,* a yellowish powder said to consist of a combination with egg albumen, dose eight to fifteen grains (0.5–1 Gm.); *sodium choleinate,* dose eight to fifteen grains (0.5–1 Gm.); *cholesterin* may be given in doses of fifteen to twenty-five grains (1.0–1.7 Gm.).

Dose, of extract of bile two to eight grains (0.12–0.5 Gm.).

EXTRACTUM GELSEMII. U. S.

EXTRACT OF GELSEMIUM Ext. Gelsem. [Powdered Extract of Gelsemium]

(ĕx-trăc'tŭm ję̆l-sĕm'ĭ-ī)

"*One gramme* of the Extract represents *four grammes* of gelsemium." *U. S.*

* "Gelsemium, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Magnesium Oxide, Starch dried at 100° C. (212° F.), each, *a sufficient quantity,* to make *two hundred and fifty grammes* [or 8 ounces av., 358 grains]. Moisten the drug with sufficient alcohol, pack it in a cylindrical percolator and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding alcohol as required, until the drug is exhausted. Recover the alcohol from the percolate, by distillation at as low a temperature as practicable, until a residue measuring about *five hundred mils* [or 16 fluidounces, 435 minims] remains in the still. Transfer this residue to a shallow dish, and evaporate it to a soft extract with frequent stirring, at a temperature not exceeding 70° C. (158° F.). Then add *fifty grammes* [or 1 ounce av., 334 grains] of a mixture of *one part* of magnesium oxide and *three parts* of the dried starch, mix well, spread the mass in a thin layer on glass or tinned-metal plates or in a porcelain dish and continue the drying in an air bath, at a temperature not exceeding 70° C. (158° F.), until thoroughly dry. Reduce the extract to a fine powder, weigh it, and add sufficient of the mixture of magnesium oxide and dried starch, made in the same proportion as before, to make the finished product weigh *two hundred and fifty grammes* [or 8 ounces av., 358 grains]. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

Dose, one-eighth to one-fourth of a grain (0.008-0.016 Gm.).

EXTRACTUM GENTIANÆ. U. S., Br.

EXTRACT OF GENTIAN Ext. Gentian.

(ĕx-trăc'tŭm gĕn-tī-ā'næ)

Extrait de Gentiane, *Fr. Cod.;* **Extractum Gentianæ,** *P. G.;* **Enzianextrakt,** *G.;* **Estratto di genzian acquoso,** *It.;* **Extracto acuoso de genciana,** *Sp.*

* "Gentian, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Water, *a sufficient quantity.* Moisten the powder with sufficient water, and allow it to macerate for twenty-four hours; then pack it in a conical percolator, and gradually pour water upon it until the drug is exhausted. Reduce the liquid to *two thousand mils* [or 67 fluidounces, 301 minims] by boiling, strain it, and then evaporate it to a pilular consistence on a water bath." *U. S.*

"Infuse Gentian Root in ten times its weight of Distilled Water for two hours; boil for fifteen minutes; pour off; press; strain; evaporate the liquid to a soft extract." *Br.*

The plan of percolation with cold water is admirably adapted to the extraction of the active principles of gentian. By the use of cold water, starch and pectic acid are left behind, while any albumen that may be taken up is disposed of by the subsequent boiling and straining.

The extract, however, may be advantageously made by macerating the root in two parts of water for thirty-six hours, then expressing in a powerful press, again macerating with additional water, and in like manner expressing, and evaporating the united expressed liquors. Guibourt and Cadet de Vaux obtained by maceration in cold water an extract not only greater in amount, but also more transparent, more bitter, and possessing more of the color and odor of the root, than that prepared by decoction. Guibourt attributes this result to the circumstance that, as gentian contains little if any starch, it yields nothing to boiling which it will not also yield to cold water, while decoction favors the combination of a portion of the coloring matter with the lignin. But this opinion requires modification, now that it is understood that gentian contains pectic acid, which water will extract when boiling hot, but not when cold. Gentian, according to Brande, yields half its weight of extract by decoction.

As ordinarily procured, the extract of gentian has an agreeable odor, is very bitter, and of a dark brown color approaching to black, shining, and tenacious. It is frequently used as a tonic, in the form of pill, either alone or in connection with metallic preparations; but the practice of some pharmacists of using it indiscriminately as a pill excipient is deserving of severe censure.

Dose, from two to eight grains (0.12–0.5 Gm.).

EXTRACTUM GLYCYRRHIZÆ. U. S.

EXTRACT OF GLYCYRRHIZA Ext. Glycyrrh. [Extract of Licorice]

(ĕx-trăc'tŭm glĭ̆ç-ĭr-rhī'zæ)

"The commercial Extract of Glycyrrhiza." *U. S.*

Extractum Liquiritiæ; Liquorice, Licorice; Extrait de Réglisse, *Fr. Cod.;* **Suc de Réglisse, Sucre noir,** *Fr.;* **Succus Liquiritiæ,** *P. G.;* **Lakriz, Lakritzensaft, Süssholzsaft,** *G.;* **Estratto di liquirizia, Sugo di liquirizia,** *It.;* **Extracto acuoso de regaliz, Regaliza en ballos,** *Sp.*

Licorice is an article of export from the north of Spain, particularly Catalonia, where it is obtained in the following manner. The roots of

the *G. glabra,* having been dug up, thoroughly cleansed, and half dried by exposure to the air, are cut into small pieces, and boiled in water until the liquor is saturated. The decoction is then allowed to rest, and, after the dregs have subsided, is decanted, and evaporated to the proper consistence. The extract, thus prepared, is formed into rolls from five to six inches long by an inch in diameter, which are dried in the air, and wrapped in laurel leaves.

The British Pharmacopœia gives a process for making extract of licorice. (See page 453.) The U. S. Pharmacopœia directs that not less than 60 per cent. of it should be soluble in cold water.

Much licorice is prepared in Calabria, according to Fée, from the *G. echinata,* which abounds in that country. The process is essentially the same as that just described, but conducted with greater care, and the Italian licorice is purer and more valuable than the Spanish. It is in cylinders, generally somewhat smaller than the Spanish, and usually stamped with the manufacturer's brand. Most of the extract brought to this country comes from Messina and Catania in Sicily and Naples, from Seville and Saragossa in Spain, and from Smyrna in Turkey. Perhaps in no other part of the world is more licorice consumed than in the United States, from four to five thousand tons having been imported annually before 1860; but the article is now made on an extensive scale in this country, very successfully, with the best modern appliances, and of such good quality as to have almost driven the foreign article out of the market. The principal use of Extract of Licorice is in the manufacture of chewing tobacco, that in the form of rolls as sold by the druggists being a comparatively small portion of the whole amount consumed.

Crude Licorice, Licorice Paste, or Licorice Mass, as it is variously termed, is found in the market in cases ranging from two hundred and fifty to four hundred pounds, of a hard pilular consistence and, as its name implies, in a mass, which has been run into the case while hot and then allowed to cool.

Licorice is usually in cylindrical rolls, somewhat flattened, and often covered with bay-leaves. We have seen it abroad and in this market in large cubical masses. When good, it is black, dry, brittle, breaking with a shining fracture, of a peculiar sweet and slightly acrid or bitterish taste, and almost entirely soluble, when pure, in boiling water.

It is described officially as "in flattened cylindrical rolls or in masses, of a glossy black color externally; fracture brittle, sharp, smooth, conchoidal; taste characteristic and sweet. When pulverized it yields a brown powder. Not less than 60 per cent. of Extract of Glycyrrhiza is soluble in cold water. The yield of ash does not exceed 6 per cent." *U. S.* Neumann obtained 460 parts of aqueous extract from 480 parts of Spanish licorice. It is, however, considerably less soluble in cold water. It is often impure from accidental or fraudulent addition or careless preparation. Starch, sand, the juice of prunes, etc., are sometimes added, and carbonaceous matter, and even particles of copper, are found in it, the latter arising from the boilers in which the decoction is evaporated. In different commercial specimens examined by Chevallier he found from 9 to 50 per cent. of insoluble matter. (*J. P. C.,* xxx, 429.) This is by no means, however, always impurity. In the preparation of the extract by decoction, a portion of matter originally insoluble, or rendered so by decoction, is taken up, and is, in fact, necessary to the proper constitution of the licorice. When this is prepared with cold water, or even with hot water by simple displacement, the extract attracts moisture from the air, becomes soft, and loses the characteristic brittleness of the drug. The additional substances taken up in decoction serve to protect the extract against this change. Delondre has obtained the same result by using steam as the solvent. He prepares from the root an excellent licorice, having all the requisite qualities of color, taste, and permanence, by passing steam, in suitable vessels, through the coarse powder of the root. The vapor thoroughly penetrates the powder, and is drawn off as it condenses. With about 500 lbs. of the root, this treatment is continued for twelve hours, and repeated at the end of five days. The liquors are collected, decanted, clarified with about 4 lbs. of gelatin, and quickly evaporated. After being put into the form of cylinders, the extract is kept for ten days in a drying room, at a temperature of 25° C. (77° F.). A bitter or empyreumatic taste is a sign of inferior quality in licorice. As ordinarily found in commerce, it requires to be purified. (See *Extractum Glycyrrhizæ Purum;* also *Glycyrrhizinum Ammoniatum.*)

Licorice contains *glycyrrhizin,* $C_{24}H_{36}O_9$, a glucoside, partly free and partly in combination with ammonia, to which combination the characteristic sweet taste of licorice is due. The glycyrrhizin when boiled with dilute acids decomposes into *glycyrrhetin,* $C_{18}H_{36}O_4$, and a fermentable sugar.

According to Mellor (*A. J. P.,* 1898, 23, 54, 136) the best process for estimating glycyrrhizin is as follows: The best menstruum with which to treat the commercial powdered extract is a mixture of 40 mils ammonia water, 240 mils of alcohol, and sufficient water to make a liter. After extraction, filter, and precipitate with diluted sulphuric acid. Of twelve samples examined, the highest was a Greek licorice with 27.78 per cent., and the lowest a Spanish with 5.28 per cent. of glycyrrhizin. Of insoluble matter, the highest was a Spanish with 36.52 per cent., and the lowest a Greek with 5.95 per cent. The average yield, however, was strongly in favor of American licorice. In determining the per cent. of glycyrrhizin in the commercial

extract, the tobacco manufacturers dissolve 10 Gm. in 100 mils of water, add 200 mils of alcohol, and allow it to stand over night. The insoluble matter will then have mostly settled; the filtrate may be acidulated with sulphuric acid, and the precipitated glycyrrhizin dried and weighed. For an improvement on the foregoing method see Dwier's article in the *Analyst* for 1913, p. 367, translated from *Ann. Falsif.*, 1913, p. 252; Also Evans' Sons, Lescher and Webb method. *Proc. A. Ph. A.*, 1911, 57 from *Chem. Ztg.*, 1911, No. 92.

The so called *refined licorice*, found in commerce in small cylindrical pieces not thicker than a pipestem, is prepared by dissolving the impure extract in water without boiling, straining the solution, and evaporating. The object of this process is to separate not only the insoluble impurities, but also the acrid oleoresinous substance which is extracted from the licorice root and is necessarily mixed with the unrefined extract. It is customary to add, during the process, a portion of sugar, gum, flour, starch, or perhaps glue. These additions, or something equivalent, are necessary to obviate the deliquescent property of the pure licorice. According to Delondre, 15 per cent. of gum is the proper proportion, when this substance is used; Geiseler has found sugar of milk to lessen the disposition of the extract to absorb moisture; but he considers the best addition, on the whole, to be very finely powdered licorice root, which should be used in the proportion of 1 part to 16 of the purified extract. (*A. J. P.*, xxviii. 225.) The preparation is sometimes attacked by small worms, probably in consequence of the farinaceous additions. Excellent licorice is prepared in some parts of England, from the root cultivated in that country. The *Pontefract cakes* are small lozenges of licorice made in the vicinity of Pontefract, England. For methods of assaying extract of licorice, see *A. J. P.*, 1896, 663; also 1898, 23, 136.

Uses.—Licorice has some demulcent property and is a popular addition to various lozenges. In large quantities it is somewhat laxative. Its most important rôle in medicine, however, is for the purpose of disguising the taste or covering the acrimony of various drugs such as quinine or ammonium chloride. It is also used to impart consistency to pills and troches.

Off. Prep.—Trochisci Ammonii Chloridi, *U. S.*; Trochisci Cubebæ, *U. S.*

EXTRACTUM GLYCYRRHIZÆ PURUM. U. S. (Br.)

PURE EXTRACT OF GLYCYRRHIZA Ext. Glycyrrh. Pur.

(ĕx-trăc'tŭm glўç-yr-rhī'zæ pū'rŭm)

Extractum Glycyrrhizæ, *Br.;* Extract of Liquorice; Extractum Glycyrrhizæ Depuratum, Succus Liquiritiæ, Depuratus; Extrait de Réglisse pur, *Fr.;* Succus Liquiritiæ depuratus, *P. G.;* Gereinigter Süssholzsaft, Reines Lakriz, *G.*

* "Glycyrrhiza, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Ammonia Water, *one hundred and fifty mils* [or 5 fluidounces, 35 minims]; Water, Chloroform Water, each, *a sufficient quantity.* Mix the ammonia water with *three thousand mils* [or 101 fluidounces, 212 minims] of water, and, having moistened the powder with *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of the mixture, allow it to macerate in a closed vessel for twenty-four hours. Then pack it lightly in a cylindrical percolator, and gradually pour upon it, first the remainder of the menstruum, and then chloroform water, until the glycyrrhiza is exhausted. Evaporate the liquid in a porcelain dish on a water bath, to a pilular consistence." *U. S.*

"Licorice Root, in No. 20 powder, 1000 *grammes;* Chloroform Water, 5000 *millilitres.* Mix the Liquorice Root with one-half of the Chloroform Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Chloroform Water and set aside for six hours; strain; press; mix the strained liquids; heat to 100° C. (212° F.); strain through flannel; evaporate to a soft extract." *Br.*

The necessity for a pure extract of licorice must be apparent to every pharmacist; the very variable quality of the commercial extract has frequently led to disappointment. The official process affords a preparation which is unexceptionable, the ammonia rendering the glycyrrhizin soluble, yet care must be taken in its evaporation, as it is very easily injured by too much heat, which gives it an empyreumatic taste, destroying at once its usefulness as an agreeable adjuvant. Extract of licorice is incompatible with acids of all kinds which precipitate the glycyrrhizin.

EXTRACTUM HYDRASTIS. U. S.

EXTRACT OF HYDRASTIS Ext. Hydrast. [Extract of Golden Seal, Powdered Extract of Hydrastis]

(ĕx-trăc'tŭm hў-drăs'tĭs)

"Extract of Hydrastis yields not less than 9 per cent. nor more than 11 per cent. of the ether-soluble alkaloids of hydrastis. *One gramme* of the Extract represents about *four grammes* of hydrastis." *U. S.*

* "Hydrastis, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Tartaric Acid, *five grammes* [or 77 grains]; Alcohol, Magnesium Oxide, Starch, dried at 100° C. (212° F.), each, *a sufficient quantity.* Dissolve the tartaric acid in *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of alcohol, moisten the drug with sufficient of this solution and pack in a cylindrical percolator; then add enough of the acidified alcohol, followed by alcohol if necessary, to saturate the powder and leave a stratum above it. When the liquid begins to

drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding alcohol as required, until the drug is exhausted. Recover the alcohol from the percolate by distillation, and evaporate the residue to a soft extract, with frequent stirring, at a temperature not exceeding 70° C. (158° F.). Add *fifty grammes* [or 1 ounce av., 334 grains] of a mixture of *one part* of magnesium oxide and *three parts* of the dried starch, mix thoroughly and spread the mass in a thin layer on glass or tinned-metal plates or in a porcelain dish and continue the drying in an air bath at a temperature not exceeding 70° C. (158° F.), until thoroughly dry. Then reduce the extract to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the powder and add to this enough of the mixture of magnesium oxide and dried starch, made in the same proportion as before, to make the finished Extract contain 10 per cent. of the ether-soluble alkaloids of hydrastis. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

" **Assay.**—Introduce 3 Gm. of Extract of Hydrastis into a 250 mil flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 mils of ether and 5 mils of ammonia water. Shake the mixture vigorously every ten minutes during a half hour, and when the dregs have settled decant 100 mils of the clear liquid, representing *two grammes* of the Extract. Proceed as directed under *Belladonnæ Radix,* eleventh line of the Assay, beginning with the word " Filter," modifying the process there given by using ether instead of chloroform for the final shaking out of the alkaloids, and drying the residue to constant weight at 100° C. (212° F.), instead of titrating it. The weight will be the amount of ether-soluble alkaloids from *two grammes* of Extract of Hydrastis," *U. S.*

Uses.—This extract was introduced into the U. S. P. IX to furnish a convenient method of administering hydrastis (see *Hydrastis*).

Dose, five to ten grains (0.3–0.6 Gm.).

EXTRACTUM HYOSCYAMI. U. S., Br.

EXTRACT OF HYOSCYAMUS Ext. Hyosc.

(ĕx-trăc'tŭm hȳ-o̤s-cȳ'a̤-mī)

"Extract of Hyoscyamus yields not less than 0.22 per cent. nor more than 0.28 per cent. of the alkaloids of hyoscyamus. *One gramme* of the Extract represents about *four grammes* of hyoscyamus." *U. S.* " Extract of Hyoscyamus contains in 100 grammes 0.3 gramme of the alkaloids of Hyoscyamus Leaves." *Br.*

Extract of Henbane; Extrait de Jusquiame (feuille), *Fr. Cod.;* Extractum Hyoscyami, *P. G.;* Bilsenkrautextrakt, *G.;* Estratto di giusquiamo idroalcoolico, *It.;* Extracto alcohólico de beleno, *Sp.*

* " Hyoscyamus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glucose, Alcohol, Water, each, *a sufficient quantity.* Moisten the powder with sufficient of a mixture of *three volumes* of alcohol and *one volume* of water, pack it firmly in a cylindrical percolator and add enough menstruum, using the same proportion of alcohol and water as before, to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum of the same strength until the drug is exhausted. Recover the alcohol by distillation and evaporate the residue, with frequent stirring, at a temperature not exceeding 70° C. (158° F.), until it is reduced to a pilular consistence. Mix the mass thoroughly and weigh it. Assay a portion of this extract as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the mass and to this add enough glucose to make the finished Extract contain 0.25 per cent. of the alkaloids of hyoscyamus. Mix thoroughly." *U. S.*

" Hyoscyamus Leaves, in No. 40 powder, Alcohol (70 per cent.) of each, *a sufficient quantity.* Reduce ten grammes of the Hyoscyamus Leaves to No. 60 powder, and determine the proportion of alkaloids present by the process described under 'Belladonnæ Folia.' Moisten one thousand grammes of the Hyoscyamus Leaves with two hundred and fifty millilitres of the Alcohol, pack firmly in a percolator, and percolate with more of the Alcohol until four thousand millilitres of percolate have been obtained. Determine the proportion of total solids in the percolate by evaporating twenty millilitres, drying the residue at 80° C. (176° F.), and weighing. Determine also the proportion of alkaloids in the percolate by the process described under ' Tinctura Belladonnæ.' Having thus determined the proportion of total solids and of alkaloids in the percolate, proceed as directed under ' Extractum Belladonnæ Siccum ' to prepare a dry Extract of Hyoscyamus containing 0.3 per cent. of alkaloids. Examined by the process described under ' Extractum Belladonnæ Siccum,' Extract of Hyoscyamus is found to contain in 100 grammes 0.3 gramme of the alkaloids of Hyoscyamus Leaves. *Limit of error* 0.015 gramme in excess or defect." *Br.*

" This Extract may be used when the Extractum Hyoscyami of the International Agreement is required. It contains 0.3 per cent. of the alkaloids of Hyoscyamus Leaves." *Br.*

" **Assay.**—Proceed as directed under *Extractum Belladonnæ Foliorum* (Pilular), page 444, modifying the process there given by using 5 Gm. of Extract of Hyoscyamus instead of 2 Gm. of extract of belladonna leaves. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the alkaloids of hyoscyamus." *U. S.*

The U. S. P. IX introduced a special process for this extract, instead of evaporating the fluid extract as did the U. S. P. VIII. The British Pharm., 1914, discarded the process for making the extract from the fresh leaves and adopted percolation and evaporation of the percolate of dried leaves so that both pharmacopœias are practically in accord. The strength is not quite the same, the U. S. P. IX requires not less than 0.22 per cent. nor more than 0.28 per cent. of alkaloids while the Br. Pharm., 1914, requires not less than 0.3 per cent. of alkaloids. For an account of the disadvantages of the extract from the fresh leaves see U. S. Dispensatory, 19th ed., p. 478.

Dose, from one to two grains (0.065–0.13 Gm.).

EXTRACTUM KRAMERIÆ. Br.

EXTRACT OF KRAMERIA

(ĕx-trăc'tŭm krą-mē'rĭ-æ)

Extract of Rhatany; Extractum Ratanhæ; Extrait de Ratanhia, *Fr. Cod.;* Ratanhæxtrakt, *G.;* Estratto di ratania acquoso, *It.;* Extracto acuoso de ratania, *Sp.*

"Exhaust Krameria Root, in No. 10 powder, with Distilled Water by the *percolation process;* evaporate the percolate to dryness." *Br.*

This extract was deleted from the U. S. P. IX, but has been introduced in the N. F. IV as a powdered extract (see Part III). In the U. S. P. VIII it was made by percolating the drug with water and evaporating the liquid as in the British process above. The wood of the root yielded to Procter only 6.8 per cent. of extract, while the bark separated from the wood yielded 33 per cent. As the wood is of difficult pulverization, the inference is obvious that, in powdering the roots, the ligneous portion may be rejected with advantage. (*A. J. P.,* xiv, 270.) As a prolonged exposure of the infusion to the air is attended with the absorption of oxygen and the production of insoluble apothem, it is desirable that the evaporation should be conducted rapidly, or in a vacuum. There scarcely appears to be occasion, in the case of rhatany, for heating and filtering the infusion before evaporation as required by the U. S. P. VIII process as the only use of which is to get rid of albumen, and this is not among the recognized ingredients of the root.

Very inferior extracts of rhatany are often sold. Such is the South American extract, which has been occasionally imported. As the product obtained by decoction is greater than that afforded by the official plan, the temptation to substitute the former is not always resisted, although it has been shown to contain nearly 50 per cent. of insoluble matter. Some druggists prepare the extract with an alcoholic menstruum, with a view to the greater product, but the extract thus prepared has from 20 to 30 per cent. less of the active principle than the official.

Extract of krameria should have a reddish-brown color, a smooth shining fracture, and a very astringent taste, and should be almost entirely soluble in water. Its virtues may be considered as in proportion to its solubility. It is much used for all the purposes for which the astringent extracts are employed.

Dose, from five to twenty grains (0.32–1.3 Gm.).

Off. Prep.—Trochiscus Krameriæ, *Br.;* Trochiscus Krameriæ et Cocainæ, *Br.*

EXTRACTUM MALTI. U. S.

EXTRACT OF MALT Ext. Malt.

(ĕx-trăc'tŭm mâl'tī)

Essence (Extrait) de Malt, *Fr.;* Malzextrakt, *G.*

* "Malt, in coarse powder, not finer than No. 12, *one thousand grammes* [or 35 ounces av., 120 grains]; Water, *a sufficient quantity.* Pour *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of water upon the powder contained in a suitable vessel and macerate for six hours, then add *four thousand mils* [or 135 fluidounces, 122 minims] of water, heated to 60° C. (140° F.), and digest the mixture for one hour on a water bath at a temperature not exceeding 60° C. (140° F.). Strain the mixture, express, filter the strained liquid, and, by means of a water bath or vacuum apparatus, evaporate the liquid, at a temperature not exceeding 60° C. (140° F.), until it has a specific gravity of not less than 1.350 nor more than 1.400 at 25° C. (77° F.)." *U. S.*

Under the name of extract of malt, two distinct preparations have been put upon the market, the one being a liquid similar to beer, the other, the official extract prepared from malt, composed chiefly of dextrin and glucose, with some albumen and phosphates. The object of the U. S. process is to obtain all of the soluble principles of malt in a permanent form. To secure this, strict attention to the details of the process is necessary. Good extract of malt should contain no starch, have the consistence of thick honey, a brown color, and should be free from empyreumatic taste. A great deal of commercial extract of malt is adulterated with glucose to a surprising extent. A *dry extract of malt* has come into extensive use as an infant's food, made by artificially drying the thick syrupy extract. It is in the form of a straw-colored, coarse powder, and is given dissolved in milk or water.

O. F. Romer and H. R. Randoll of Brooklyn, have patented several improvements in the process of making extract of malt,—namely, 1, the properly ground malt is treated with an alkaline solution, in order to neutralize the fatty acids which usually impart a bad taste to the product; 2, the extract is separated from the solid matters by pressing in press cloths, whereby it is obtained as a clear liquid with scarcely any loss. (*N. R.,* 1880, 179.) Pharmaceutically, extract of malt has been used as an emulsifying agent; it makes

a good basis for a cod liver oil emulsion, for which purpose it is admirably adapted therapeutically. For therapeutic properties see *Maltum.*

Dose, from one to four fluidrachms (3.75 to 15 mils).

EXTRACTUM NUCIS VOMICÆ.
U. S., (Br.)

EXTRACT OF NUX VOMICA Ext. Nuc. Vom.
[Powdered Extract of Nux Vomica, Nucis Vomicæ Extractum, P. I.]

(ĕx-trăc'tŭm nū'cĭs vŏm'ĭ-cæ)

"Extract of Nux Vomica yields not less than 15.2 per cent. nor more than 16.8 per cent. of the alkaloids of nux vomica." *U. S.*

"Dry Extract of Nux Vomica contains in 100 grammes 5 grammes of strychnine." *Br.*

Extractum Nucis Vomicæ Siccum, *Br.;* Dry Extract of Nux Vomica; Extractum Nucum Vomicarum Spirituosum (vel Alcoholicum); Extrait de Noix Vomique, *Fr. Cod.;* Extractum Strychni, *P. G.;* Weingeistiges Krähenaugenextrakt, Brechnussextrakt, Strychnossamenextrakt, *G.;* Estratto di noce vomica alcoolico, *It.;* Extracto alcoholico de nuez vomica, *Sp.*

* "Nux Vomica, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, Purified Petroleum Benzin, Diluted Sulphuric Acid, Ammonia Water, Chloroform, Magnesium Oxide, Starch, dried at 100° C. (212° F.), each, *a sufficient quantity.* Moisten the drug with sufficient of a mixture of *three volumes* of alcohol and *one volume* of water, pack it firmly in a cylindrical percolator, and add enough of the menstruum, using the same proportion of alcohol and water as before, to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding the menstruum as required, until the percolate passes but faintly imbued with bitterness, and the drug is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable and concentrate the liquid until the residue measures about *two hundred mils* [or 6 fluidrachms, 366 minims]. Transfer this residue to a flask or separator, using a little warm menstruum made of the same proportion of alcohol and water originally used, to rinse the still, and add the rinsing to the separator. Then add *one hundred and fifty mils* [or 5 fluidounces, 35 minims] of water and *two hundred mils* [or 6 fluidounces, 366 minims] of purified petroleum benzin and shake the mixture thoroughly for several minutes. Allow the liquids to separate and decant the benzin layer as closely as possible; again add to the residue *one hundred mils* [or 3 fluidounces, 183 minims] of purified petroleum benzin, agitate, and decant the benzin as before. Wash the mixed benzin solutions, in a separator, with a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of water and *ten mils* [or 162 minims] of diluted sulphuric acid, separate the aqueous layer and repeat the washing twice with fresh portions, *one hundred mils* [or 3 fluidounces, 183 minims] each, of water and acid made in the same proportion as before. Collect the aqueous solutions in a separator, render the liquid alkaline by the addition of ammonia water and shake it out with three portions of chloroform, *twenty mils* [or 325 minims], *ten mils* [or 162 minims], and *ten mils* [or 162 minims], respectively. Add the combined chloroform solutions to the extract and evaporate the mixture to dryness on a water bath with frequent stirring. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the product and add to this enough of a mixture of magnesium oxide, *one part,* and of the dried starch, *three parts,* to make the finished Extract contain 16 per cent. of the alkaloids of nux vomica. Reduce the mixture to a fine powder, mix thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

"Liquid Extract of Nux Vomica, Calcium Phosphate, of each, *a sufficient quantity.* Evaporate ten millilitres of the Liquid Extract in a flat-bottomed dish and dry at 100° C. (212° F.). The weight of the dry extract thus obtained deducted from three grammes gives the weight of Calcium Phosphate to be added to each ten millilitres of the Liquid Extract. Take one hundred parts by volume of the Liquid Extract; recover the alcohol by distillation; add sufficient of the Calcium Phosphate, as indicated by the above determination, to produce, when dried at 100° C. (212° F.), and reduced to a fine powder, thirty parts by weight of the Dry Extract." *Br.*

"3 grammes of Dry Extract of Nux Vomica, when exhausted with *alcohol* (70 per cent.), afford a liquid which when tested by the process described under 'Extractum Nucis Vomicæ Liquidum' yield 0.15 gramme of strychnine, representing in 100 grammes of the Dry Extract 5 grammes of strychnine. *Limit of error* 0.2 gramme in excess or defect. This Dry Extract contains 5 per cent. of strychnine." *Br.*

"**Assay.**—Introduce 3 Gm. of Extract of Nux Vomica into a 250 mil flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 mils of a mixture of ether, 2 *volumes,* and chloroform, 1 *volume,* followed by 5 mils of ammonia water. Shake the mixture vigorously every ten minutes during half an hour, and when the dregs have settled decant 100 mils of the clear liquid, representing *two grammes* of the Extract. Proceed as directed under *Belladonnæ Radix,* twelfth line of the Assay, beginning with the word "Filter," *modifying the process* there given by dissolving the alkaloidal residue in 10 mils of tenth-normal sulphuric acid V.S. instead of 5 mils.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 36.4 milligrammes of the alkaloids of nux vomica." *U. S.*

Extract of Nux Vomica, U. S. P. IX, is a powdered extract containing 16 per cent. of total alkaloids. This alkaloidal strength is the standard adopted by The Brussels Protocol. The U. S. P. VIII standard was 5 per cent. of strychnine and the British Pharm. (1914) retained its former standard of 5 per cent. of strychnine and directed the evaporation of the standardized liquid extract of nux vomica.

Extract of nux vomica (U. S. P. VIII) differed from that of the U. S. Pharm. 1890 in its mode of preparation. Acetic acid is the most effective menstruum for nux vomica, but it has the disadvantage of also extracting inert constituents; it leaves the fixed oil in the marc and this is a great point in its favor, but acetic acid was discarded by the U. S. P. IX. and a menstruum of 3 volumes of alcohol and 1 volume of water substituted; in addition the fixed oil is separated and the dissolved alkaloids washed out and incorporated with the extract.

Dose, one-fourth to one-half of a grain (0.016–0.032 Gm.).

Off. Prep.—Pilulæ Aloes et Podophylli Compositæ, *N. F.;* Pilulæ Ferri, Quininæ Aloes et Nucis Vomicæ, *N. F.;* Pilulæ Laxativæ Post Partum, *N. F.*

EXTRACTUM OPII. U. S. (Br.)

EXTRACT OF OPIUM Ext. Opii [Powdered Extract of Opium, Opii Extractum P. I.]

(ĕx-trăc'tŭm ō'pĭ-ī)

"Extract of Opium yields not less than 19.5 per cent. nor more than 20.5 per cent. of anhydrous morphine. *One gramme* of the Extract represents about *two grammes* of opium." *U. S.*

"Dry Extract of Opium contains in 100 grammes 20 grammes of morphine, calculated as anhydrous." *Br.*

Extractum Opii Siccum, *Br.*; Dry Extract of Opium; Extractum Thebaicum; Extrait d'Opium, *Fr. Cod.;* Extrait Thébaique, *Fr.;* Extractum Opii, *P. G.;* Opiumextrakt, *G.;* Estratto di oppio acquoso, *It.;* Extracto acuoso de opio, *Sp.*

* "Opium, cut in small pieces, *one hundred grammes* [or 3 ounces av., 231 grains]; Starch, dried at 100° C. (212° F.), Water, each, *a sufficient quantity.* Macerate the opium with *three hundred mils* [or 10 fluidounces, 69 minims] of hot water until softened, then rub to a smooth paste. Add to this *one hundred grammes* [or 3 ounces av., 231 grains] of clean, white sand and mix thoroughly. Transfer the mixture to a percolator and allow the percolation to proceed, gradually adding water until the opium is exhausted. Evaporate the percolate to dryness in a shallow evaporating dish, on a water bath, reduce the product to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of anhydrous morphine in the remainder of the powder and add to this enough of the dried starch to make the finished Extract contain 20 per cent. of anhydrous morphine. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

"Exhaust sliced Opium with about five times its weight of Distilled Water; strain the liquid through flannel; cool and ascertain its volume. Determine the percentage of morphine present in forty millilitres of this liquid by the process described under 'Tinctura Opii,' and determine also the percentage of total solids dried at 100° C. (212° F.). Add to the remainder of the liquid sufficient Calcium Phosphate to yield an extract which, when dried at 100° C. (212° F.), contains 20 per cent. of morphine; evaporate to dryness, powder, and finally dry at 100° C. (212° F.). Examined by the process described under 'Opium,' Dry Extract of Opium is found to contain in 100 grammes 20 grammes of morphine, calculated as anhydrous. *Limit of error* 1 gramme in excess or defect. This Dry Extract contains 20 per cent. of morphine." *Br.*

"**Assay.**—Dissolve 4 Gm. of Extract of Opium in 5 mils of distilled water, add gradually, with constant stirring, 25 mils of distilled water, filter, and wash the filter and residue with sufficient distilled water to make the solution measure exactly 50 mils. Then proceed as directed under *Opium,* twenty-seventh line of the Assay, beginning with the word "Place." The morphine obtained represents *two grammes* of Extract of Opium." U. S.

The process for the U. S. P. extract differs from that formerly official in several particulars, opium being used instead of powdered opium, and the extract is assayed, and the percentage of morphine adjusted to 20 per cent., so that the extract of opium can now be depended upon to contain slightly more than twice as much morphine as opium of the minimum official strength.

The U. S. P. process is an improvement over those formerly official; in addition to definite strength of the extract, its reduction to pulverulent form will enable pharmacists to dispense it more accurately and conveniently.

As purely aqueous preparations of opium have been found to agree better with certain individuals than opium alone or its alcoholic preparations, there is reason to believe that there are in the crude drug one or more principles, which are capable of causing nausea, headache, nervous disturbances, etc., and which are insoluble in water, though extracted by alcohol or ether. (See *Opium Deodoratum.*)

Dose, one-sixth to one grain (0.01–0.06 Gm.).

Off. Prep.—Extractum Opii Liquidum, *Br.*

EXTRACTUM OPII LIQUIDUM. Br.

LIQUID EXTRACT OF OPIUM

(ĕx-trăc'tŭm ō'pĭ-ī lĭq'uĭ-dŭm)

"Liquid Extract of Opium contains in 100 millilitres 0.75 gramme of morphine, calculated as anhydrous." *Br.*

"Dry Extract of Opium, 37.5 *grammes;* Alcohol (90 per cent.), 200.0 *millilitres;* Distilled

Water sufficient to produce 1000.0 *millilitres*. Mix the Extract with seven hundred *millilitres* of the Distilled Water; set aside in a cool place for twenty-four hours, stirring frequently; add the Alcohol; set aside again for twenty-four hours; filter; wash the filter with sufficient Distilled Water to produce the required volume." *Br.*

"Examined by the process described under 'Tinctura Opii,' Liquid Extract of Opium is found to contain in 100 millilitres 0.75 gramme of morphine, calculated as anhydrous. *Limit of error* 0.05 gramme in excess or defect. This Liquid Extract contains 0.75 gramme of morphine in 100 millilitres; 110 minims contains ¾ grain." *Br.*

It is a good preparation, one which has long been needed; because of its absence from the Pharmacopœia empirical preparations have obtained a certain vogue. It is well known that in opium there are principles soluble in alcohol but not in water, which often produce various disagreeable effects not experienced from the aqueous extract; what was wanted was a liquid preparation meeting this demand. All that was required was to make an aqueous solution of solid extract, and to add something to preserve it. The British Pharmacopœia uses alcohol for the purpose, and in the original formula employed it in such proportion that an Imperial pint of the liquid should contain three fluidounces of the spirit, or between one-sixth and one-seventh by measure. But this amount of alcohol, according to Squire, is insufficient for its preservation, and should be doubled. In the Br. Pharmacopœia (1898) the spirit was increased; but even with this increase the spirit constitutes only one-fifth, which is considerably short of the proportion recommended by Squire. A preparation similar to the British was made some years since by Eugene Dupuy, of New York. (See *Opium.*) In the *Deodorized Tincture of Opium* of the U. S. Pharmacopœia the advantages of the preparation have, we think, been still better secured.

Dose, five to thirty minims (0.3–1.8 mils).

EXTRACTUM PHYSOSTIGMATIS. U. S.

EXTRACT OF PHYSOSTIGMA [Ext. Physostig. [Powdered Extract of Physostigma]

(ĕx-trăc'tŭm phȳ-sǫ-stĭg'mą-tĭs)

"Extract of Physostigma yields not less than 1.7 per cent. nor more than 2.3 per cent. of the alkaloids of physostigma. *One gramme* of the Extract represents about *thirteen grammes* of physostigma." *U. S.*

Extract of Calabar Bean; Extractum Fabæ Calabaricæ; Extrait de Fève de Calabar, *Fr. Cod.*; Kalabarbohnenextrakt, Physostigmaextrakt, *G.*

* "Physostigma, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Tartaric Acid, *five grammes* [or 77 grains]; Purified Petroleum Benzin, Starch, dried at 100° C. (212° F.), Alcohol, Water, each, *a sufficient quantity*. Dissolve the tartaric acid in *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of a mixture of *three volumes* of alcohol and *one volume* of water, moisten the drug with sufficient of this solution, and pack it in a cylindrical percolator; then add enough of the acidified alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding the remainder of the prepared menstruum and then a mixture of *three volumes* of alcohol and *one volume* of water until the drug is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable and concentrate the remaining liquid at a temperature not exceeding 70° C. (158° F.) until the residue measures about *two hundred mils* [or 6 fluidounces, 366 minims]. Transfer the residue to a flask, using a little warm menstruum, made of the same proportion of alcohol and water as before, to rinse the still, and add the rinsing to the residue in the flask. Then add *one hundred mils* [or 3 fluidounces, 183 minims] of water and *two hundred and fifty mils* [or 8 fluidounces, 218 minims] of purified petroleum benzin and shake the mixture thoroughly for several minutes. Allow the liquids to separate and decant the benzin layer as closely as possible; again add to the residue *two hundred mils* [or 6 fluidounces, 366 minims] of purified petroleum benzin, agitate, and, after allowing the liquids to separate, decant the benzin layer as before and reject the benzin solutions. Transfer the residue to a shallow evaporating dish, rinse the separator with a little of the warm menstruum, add the rinsings to the residue in the dish and evaporate it to pilular consistence at a temperature not exceeding 70° C. (158° F.). Now add *twenty grammes* [or 309 grains] of the dried starch, thoroughly incorporate it, set the extract aside in a current of warm air until dry, then reduce the product to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the powder and add to this enough of the dried starch to make the finished Extract contain 2 per cent. of the alkaloids of physostigma. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

"**Assay.**—Introduce 3 Gm. of Extract of Physostigma into a 250 mil flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 mils of ether and proceed as directed under *Physostigma*, third line of the Assay, beginning with the word "stopper."

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 27.52 milligrammes of the alkaloids of physostigma." *U. S.*

This extract was formerly official in the British Pharmacopœia but has not been admitted to the 1914 Edition.

As alcohol is the best solvent for the active principles of the bean, it is preferred in making the extract, while the addition of tartaric acid is to facilitate the solution of the alkaloids.

Dose, from one-sixth to one-half of a grain (0.01–0.032 Gm.).

EXTRACTUM RHEI. U. S., Br.

EXTRACT OF RHUBARB Ext. Rhei [Powdered Extract of Rhubarb]

(ĕx-trăc'tŭm rhē'ī)

"*One gramme* of the Extract represents *two grammes* of rhubarb." *U. S.*

Extractum Rhei Alcoholicum; Extrait de Rhubarbe, *Fr. Cod.;* Extractum Rhei, *P. G.;* Rhabarberextrakt, *G.;* Estratto di rabarbaro acquoso, *It.;* Extracto acuoso de ruibarbo, *Sp.*

* "Rhubarb, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Magnesium Oxide, *fifty grammes* [or 1 ounce av., 334 grains]; Starch, dried at 100° C. (212° F.), Alcohol, Water, each, *a sufficient quantity,* to make *five hundred grammes* [or 17 ounces av., 279 grains]. Moisten the drug with sufficient of a mixture of *four volumes* of alcohol and *one volume* of water, pack it in a cylindrical percolator and add enough of this menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum of the same proportion of alcohol and water as before until the drug is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable, and continue distillation until a residue of syrupy consistence remains in the still. Transfer this to a shallow dish, rinse the still with a little warm menstruum, add the rinsings to the residue in the dish, and evaporate the mixture to dryness, with frequent stirring, at a temperature not exceeding 70° C. (158° F.). Weigh the dry extract and add the magnesium oxide and sufficient of the dried starch to make the product weigh *five hundred grammes* [or 17 ounces av., 279 grains]. Reduce the mixture to a fine powder, mix thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

"Exhaust Rhubarb, in No. 20 powder, with Alcohol (60 per cent.) by the *percolation process.* Recover most of the alcohol from the percolate by distillation, and evaporate the residual liquid to dryness." *Br.*

The British extract (1914) is now nearly identical with the U. S. preparation; the menstruum used for the former is, however, slightly more aqueous. Rhubarb yields all its active matter to water and alcohol; but, unless the evaporation be performed with great care and with a moderate heat, it is certain that the purgative principle is to a greater or less extent injured or dissipated in the process, and the extract may thus become even less efficient than the root. When properly prepared, the extract has decidedly the peculiar odor of rhubarb.

Dose, from two to ten grains (0.13–0.65 Gm.).

EXTRACTUM STRAMONII. U. S.

EXTRACT OF STRAMONIUM Ext. Stramon.

(ĕx-trăc'tŭm strą-mō'nĭ-ī)

"Extract of Stramonium yields not less than 0.9 per cent. nor more than 1.1 per cent. of the alkaloids of stramonium. One gramme of the Extract represents about *four grammes* of stramonium." *U. S.*

Extrait de Stramoine (feuille), *Fr. Cod.;* Stechapfelblätterextrakt, *G.*

Pilular Extract of Stramonium

* "Stramonium, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains] Glucose, Alcohol, Water, each, *a sufficient quantity.* Moisten the powder with sufficient of a mixture of *three volumes* of alcohol and *one volume* of water and pack it in a cylindrical percolator; then add enough of this menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed gradually adding menstruum of the same strength, until the drug is exhausted. Recover the alcohol from the percolate by distillation, and evaporate the residue with frequent stirring, at a temperature not exceeding 70° C. (158° F.), to a pilular consistence. Mix the mass thoroughly and weigh it. Assay a portion of this extract as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the mass and to this add enough glucose to make the finished Extract contain 1 per cent. of the alkaloids of stramonium. Mix thoroughly." *U. S.*

"**Assay.**—Proceed as directed under *Extractum Belladonnæ Foliorum* (Pilular), page 444, using 2 Gm. of Pilular Extract of Stramonium.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the alkaloids of stramonium." *U. S.*

Powdered Extract of Stramonium

* "Stramonium, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Magnesium Oxide, *twenty grammes* [or 309 grains]; Starch, dried at 100° C. (212° F.), Alcohol, each, *a sufficient quantity.* Moisten the drug with sufficient alcohol and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed very slowly, adding alcohol as required. Reserve the first *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of percolate and continue the percolation until the second percolate measures *one thousand mils* [or 33

fluidounces, 6½ fluidrachms], or until the drug is exhausted. Transfer the second percolate to a suitable apparatus and distil off the alcohol, at as low a temperature as practicable, until a residue measuring about *one hundred mils* [or 3 fluidounces, 183 minims] remains, then add the reserved percolate and continue distillation until the residue in the still is of syrupy consistence. Transfer this residue to a shallow evaporating dish, rinse the flask or still with a small quantity of warm alcohol, and add the rinsing to the contents of the dish. Evaporate this to a soft extract, with frequent stirring, at a temperature not exceeding 70° C. (158° F.). Then add *fifty grammes* [or 1 ounce av., 334 grains] of the dried starch and continue the heating at the same temperature, with frequent stirring, until the mass is nearly dry. Now add the magnesium oxide, thoroughly incorporate it, and set the product aside in a current of warm air, until thoroughly dry. Reduce the product to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the powder and add to this enough dried starch to make the finished Extract contain 1 per cent. of the alkaloids of stramonium. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

E'we and Vanderkleed report specimens of extract of stramonium which contain a green coal tar color to simulate the chlorophyll present in extracts made from high grade leaf. This coloring matter interferes with the alkaloidal assay and must be removed by shaking out with chloroform in the acid solution. (*J. A. P. A.*, 1914, 1683.)

"**Assay.**—Proceed as directed under *Extractum Belladonnæ Foliorum* (Powdered), page 444, using 3 Gm. of Powdered Extract of Stramonium.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the alkaloids of stramonium." *U. S.*

Dose, from one-eighth to one-fourth of a grain (0.008–0.016 Gm.).

Off. Prep.—Unguentum Stramonii (from Pilular Extract), *U. S.*

EXTRACTUM STROPHANTHI. Br.

EXTRACT OF STROPHANTHUS

(ĕx-trăc'tŭm strŏ-phăn'thī)

Extrait de Strophantus Kombé (Semence), *Fr. Cod.*; Strophantusextrakt, *G.*

"Strophanthus Seeds, reduced to No. 30 powder, and dried at 45° C. (113° F.), 25 *grammes;* Ether, Alcohol (90 per cent.), Milk Sugar, in powder, of each, *a sufficient quantity.* Pack the Strophanthus Seeds in a percolator; moisten with the Ether, and macerate for twenty-four hours; then allow percolation to proceed, continuing the addition of the Ether until the liquid passes through colorless. Remove the marc from the percolator, and dry it, gradually heating it to 50° C. (122° F.). Again reduce it to powder, repack in the percolator, and moisten with the Alcohol. Macerate for forty-eight hours, then pour on successive quantities of the Alcohol, percolating slowly, until two hundred and fifty *millilitres* of liquid are obtained. Evaporate most of the alcohol; transfer the residual liquid to a tared dish; concentrate until the liquid begins to thicken; then add sufficient of the Milk Sugar to produce fifty *grammes* of Extract, in powder." *Br.*

This preparation of the British Pharmacopœia closely resembles an "abstract" of the U. S. P., 1880; an important detail, in our opinion, has been neglected in not washing the fatty matter extracted by the ether with diluted alcohol to remove active constituents held by the fatty substances, then evaporating the solution and incorporating the residue with the extract.

This extract fills a very decided want of a solid preparation of strophanthus that can be administered in pill and capsule, and is without doubt efficient. A grain of it may be considered to represent five minims of the U. S. tincture of strophanthus.

Dose, as given in the British Pharmacopœia, from one-fourth to one grain (0.016–0.065 Gm.).

EXTRACTUM SUMBUL. U.S.

EXTRACT OF SUMBUL Ext. Sumbul

(ĕx-trăc'tŭm sŭm'bŭl)

Extract of Muskroot; Extrait de Racine de Sumbul, *Fr.*; Sumbulwurzelextrakt, Moschuswurzelextrakt, *G.*

* "Sumbul, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity.* Moisten the powder with sufficient of a mixture of *four volumes* of alcohol and *one volume* of water and pack it in a cylindrical percolator; then add enough of this menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum of the same strength until the drug is exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue with frequent stirring, at a temperature not exceeding 70° C. (158° F.), to a pilular consistence." *U. S.*

Dose, two to five grains (0.13–0.32 Gm.).

EXTRACTUM TARAXACI. U. S., Br.

EXTRACT OF TARAXACUM Ext. Tarax.

(ĕx-trăc'tŭm tą-răx'ą-cī)

Extract of Dandelion; Extrait de Dent-de-lion, *Fr.*; Löwenzahnextrakt, *G.*; Estratto di tarassaco acquoso, *It.*

* "Taraxacum, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity.* Mix *one hundred and twenty-five mils* [or 4 fluid-

ounces, 109 minims] of alcohol with *eight hundred and seventy-five mils* [or 29 fluidounces, 282 minims] of water, and, having moistened the powder with a portion of the mixture, pack it in a cylindrical percolator, then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed, gradually adding menstruum of the same strength until the drug is exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue with frequent stirring, on a water bath, to a pilular consistence." *U. S.*

"Crush Taraxacum Root; press out the juice; allow the starchy matter to subside; decant; heat the liquid to 100° C. (212° F.), and maintain the temperature for ten minutes; strain; evaporate to a soft extract." *Br.*

The inspissated taraxacum juice of the former U. S. Pharmacopœias has been superseded by the present hydro-alcoholic extract, because of the very variable quality of the former; if the root is of good quality a better extract can be made by percolation and evaporation in the usual way.

The extract made from the juice is undoubtedly stronger when prepared from the root alone than from the whole plant. It is important that the root should be collected at the right season. The juice expressed from it in the spring is thin, watery, and of a feeble flavor; in the latter part of the summer, and in autumn, thick, opaque, cream-colored, very bitter, and abundant, amounting to one-third or one-half its weight. It may be collected in August, and afterwards until severe frost. According to Squire, frost has the effect of diminishing the bitterness and increasing the sweetness of the root. An extract prepared by inspissating the juice is more efficient than that prepared in the old way by decoction. The inspissation should be effected by exposing the juice in shallow vessels to a current of warm dry air, or by evaporation in a vacuum, and should not be unnecessarily protracted. Long exposure during evaporation changes the bitterness of the juice into sweetness, which is a sign of inferiority. In the British process it is wisely directed that before the evaporation of the juice it shall be exposed for a short time to a heat sufficient to coagulate the albumen, which is then separated and rejected as useless; it is indeed injurious, by favoring decomposition. As often found in the shops, the extract is dark-colored, sweet, and in all probability nearly inert. Houlton took more than an ounce of it in a day, without any sensible effect. (*P. J.*, i, 421.) When prepared from the root and leaves together, it has a greenish color. Brande states that one cwt. of the fresh root affords from twenty to twenty-five pounds of extract by decoction in water. The expressed juice yields from 11 to 25 per cent. of extract, the greatest product being obtained from plants collected in November, and the least in April and May. This extract deteriorates by keeping. It is conveniently given in an aromatic water.

Dose, from fifteen grains to a drachm (1–3.9 Gm.) three times a day.

EXTRACTUM VIBURNI PRUNIFOLII. U. S.

EXTRACT OF VIBURNUM PRUNIFOLIUM Ext. Viburn. Prun. [Powdered Extract of Viburnum Prunifolium]

(ĕx-trăc'tŭm vī-bŭr'nī pru-nĭ-fō'lĭ-ī)

"*One gramme* of the Extract represents *five grammes* of viburnum prunifolium." *U. S.*

* "Virburnum Prunifolium, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Magnesium Oxide, *five grammes* [or 77 grains]; Starch, dried at 100° C. (212° F.), Diluted Alcohol, each, *a sufficient quantity,* to make *two hundred grammes* [or 7 ounces av., 24 grains]. Moisten the powder with sufficient diluted alcohol and pack it in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding diluted alcohol as required until the viburnum prunifolium is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable and evaporate the residue to a soft extract in a shallow dish on a water bath, at a temperature not exceeding 70° C. (158° F.). Add the magnesium oxide, incorporate it thoroughly, spread the extract on glass plates and dry it by exposure to currents of warm air. Reduce the extract to a fine powder, weigh it, and add sufficient of the dried starch to make the finished product weigh *two hundred grammes* [or 7 ounces av., 24 grains]. Mix the powder thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." *U. S.*

Dose, five to ten grains (0.3–0.65 Gm.).

FEL BOVIS. U. S.

OXGALL

(fĕl bō'vĭs)

"The fresh bile of the ox, *Bos taurus* Linné (Fam. *Bovidæ*)." *U. S.*

Fel Bovinum, Fel Tauri, Bilis Bubula, Ox Bile; Bile de Bœuf, *Fr. Cod.*; Ochsengalle, Rindsgalle, *G.*; Hiel de toro, *Sp.*

Crude oxgall is rarely used for medical purposes. It is, however, frequently employed for various technical purposes, especially for cleaning cloth.

Chemical researches of a very thorough character have thrown much light on the subject of the constituents of gall. The most characteristic constituents of all galls, of whatever origin, are, first, the sodium or potassium salts of certain resinous acids known collectively as the "gall

acids," and, secondly, certain coloring matters known as "gall pigments." The gall acids thus far made known as *glycocholic acid,* $C_{26}H_{43}NO_6$; *taurocholic acid,* $C_{26}H_{45}NSO_7$; *hyoglycocholic acid,* $C_{27}H_{43}NO_5$; *hyotaurocholic acid,* $C_{27}H_{45}NSO_6$; and *chenotaurocholic acid,* $C_{29}H_{49}NSO_6$. Of these, the first two occur in oxgall as sodium salts, although sometimes (in green gall) the first one is absent. The solutions of these gall acids, as well as their alkaline salts, give on addition of sugar and a drop of sulphuric acid a clear and strong purplish-red color. (*Pettenkofer's bile test.*) Drechsel modifies Pettenkofer's test as follows. Add to the concentrated alkaline solution of the biliary salts syrupy phosphoric acid. Next add a little cane sugar, and heat the test tube by setting it in the neck of a flask containing boiling water. After a short heating a characteristic red or reddish-violet color will make its appearance, even if only traces of biliary acids are present. (*N. R.,* 1882, p. 120.)

The gall pigments are such unstable organic coloring matters that their individuality cannot be said to be thoroughly established. The researches of Staedeler (*Verhand. d. Naturf. Ges. in Zürich,* 8) and R. Maly (*Ann. Ch. Ph.,* 132, 129) have, however, given us a better knowledge of them. They are *bilirubin,* $C_{32}H_{36}N_4O_6$; *biliverdin,* $C_{32}H_{36}N_4O_9$; *bilifuscin,* $C_{16}H_{20}N_2O_4$; and *biliprasin,* $C_{16}H_{22}N_2O_6$. Of these, the first two seem to exist originally in the gall, and the others are probably derived from them. Hoppe-Seyler (*Ber. d. Chem. Ges.,* vii, p. 1065) has shown that the hemoglobin and hematin of the blood can be changed into hydrobilirubin, a derivative of bilirubin, so that the origin of these gall pigments seems to be clearly shown. Oxgall contains, in addition, cholesterin, choline, urea, fats, which are the glycerides of acetic and propionic acids, mucus and some inorganic salts, such as sodium and potassium chlorides, and sodium, potassium, calcium, and magnesium phosphates. Bile as secreted from the liver has a specific gravity of about 1.010, and contains from 1 to 3 per cent. of solid matters; in the gall-bladder, however, it becomes more concentrated and has approximately the following composition: Specific gravity, 1.025 to 1.040; total solids, 14 to 29 per cent.; glycocholates and taurocholates, 9 to 12 per cent.; cholesterin, 1.5 to 4 per cent.; lecithin and fats, 1 to 5 per cent.; soaps, 0.2 to 3 per cent.; mucin and protein matters, 2 to 4 per cent.; bile pigments, bilirubin, biliverdine, small amounts. The *sodium glycocholate* and *taurocholate* may be separated in the following manner. Dry ox bile is treated with absolute alcohol, and the tincture precipitated by ether in excess. Both salts are deposited, and the glycocholate crystallizes upon standing, the taurocholate remaining in an amorphous form, resembling oily or resinous matter. They may be separated more completely by taking advantage of their different relations to lead acetate and subacetate. Both the acids are precipitated by the subacetate, the glycocholate only by the acetate. If the deposit above referred to be dissolved in water, solution of lead acetate will throw down a lead glycocholate, while the addition of the lead subacetate to the remainder will precipitate the taurocholate. The acids may be separated from the salts of lead by sulphuric acid, and then recombined with soda.

Properties.—"A brownish-green or dark green, somewhat viscid liquid, having a characteristic odor, and a disagreeable, bitter taste. When Oxgall is shaken with water a frothy mixture is produced. Specific gravity: 1.015 to 1.025 at 25° C. (77° F.). It is neutral or faintly alkaline to litmus. A mixture of 2 drops of Oxgall and 10 mils of water, when treated, first with a drop of a freshly prepared solution of 1 part of sugar in 4 parts of water, and afterwards with sulphuric acid, cautiously added, until the precipitate first formed is redissolved, gradually acquires a brownish-red color, changing successively to carmine, purple, and violet." *U. S.*

For uses see *Extractum Fellis Bovis,* p. 450.

Off. Prep.—Extractum Fellis Bovis, *U. S.;* Fel Bovinum Purificatum, *Br.*

FERRI CARBONAS SACCHARATUS.

U. S., Br.

SACCHARATED FERROUS CARBONATE
Ferr. Carb. Sacch.

(fĕr'rī căr'bo̤-năs săc-ca̤ha̤-rā'tŭs)

"Saccharated Ferrous Carbonate contains not less than 15 per cent. of $FeCO_3$ (115.84). Preserve it in small, well-stoppered bottles, exposed to light." *U. S.* "Saccharated Iron Carbonate is ferrous carbonate, more or less oxidised, mixed with glucose. Contains not less than 50 per cent. of ferrous salts calculated as ferrous carbonate, $FeCO_3$." *Br.*

Saccharated Iron Carbonate; Saccharated Carbonate of Iron; Carbonas Ferrosus Saccharatus; Saccharure de Carbonate Ferreux, *Fr.;* Ferrum Carbonicum Saccharatum, *P. G.;* Zuckerhaltiges Kohlensaures Eisen, Zuckerhaltiges Ferrocarbonat, *G.*

* "Ferrous Sulphate, *fifty grammes* [or 1 ounce av., 334 grains]; Sodium Bicarbonate, *thirty-five grammes* [or 1 ounce av., 103 grains]; Sugar of Milk, *ten grammes* [or 154 grains]; Sugar, in fine powder, Diluted Sulphuric Acid, Distilled Water, each, *a sufficient quantity,* to make, *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the ferrous sulphate in *two hundred mils* [or 6 fluidounces, 366 minims] of hot distilled water, add a few drops of diluted sulphuric acid and filter. Dissolve the sodium bicarbonate in *five hundred mils* [or 16 fluidounces, 435 minims] of distilled water at a temperature not exceeding 50° C. (122° F.), and filter. To the solution of sodium bicarbonate, contained in a flask having a capacity of about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] gradually add the solution of ferrous sulphate, and mix thoroughly by rotating the flask. Fill the flask with boiling distilled water, cork it loosely, and set the mixture aside. When the precipitate has subsided, draw off the clear supernatant liquid by means of a siphon; fill the

flask again with hot distilled water and shake it. Again draw off the clear liquid, and repeat the washing with hot distilled water, in the same manner, until the decanted liquid gives merely a slight cloudiness with barium chloride T.S. Drain the precipitate, and transfer it to a porcelain dish containing *seventy grammes* [or 2 ounces av., 205 grains] of sugar and *ten grammes* [or 154 grains] of sugar of milk and mix intimately. Evaporate the mixture to dryness on a water bath, reduce it to powder, weigh, and mix intimately with it, if necessary, enough well-dried sugar to make the product weigh *one hundred grammes* [or 3 ounces av., 231 grains]. To minimize oxidation make this preparation in the shortest possible time." *U. S.*

"Ferrous Sulphate, 97.5 *grammes;* Glucose, 30.0 *grammes;* Sodium Carbonate, 105.0 *grammes;* Distilled Water, boiling, *a sufficient quantity.* Dissolve fifteen *grammes* of the Glucose in three hundred *millilitres* of the Distilled Water, and dissolve the Ferrous Sulphate in the solution. Dissolve the Sodium Carbonate in one hundred and fifty *millilitres* of the Distilled Water, and to this add the solution of the Ferrous Sulphate, stirring constantly. Then add four hundred *millilitres* of the Distilled Water, mix thoroughly, and allow the precipitate to subside. Decant the supernatant liquid, and wash the precipitate with two successive quantities, each of four hundred *millilitres,* of the Distilled Water. Mix the washed precipitate with the remainder of the Glucose, and dry at a temperature not exceeding 100° C. (212° F.). Powder the product, and preserve it in a stoppered bottle." *Br.*

This was introduced into the U. S. P. in 1880; the process is identical with that of the former German Pharmacopœia. When solutions of ferrous sulphate and sodium carbonate are mixed together, there are formed, by double decomposition, sodium sulphate which remains in solution, and ferrous carbonate which falls as a pale-blue precipitate. This precipitate begins immediately to alter in nature by the absorption of oxygen, and, if washed and dried in the ordinary way, becomes ferric oxide, associated with a small quantity of the ferrous carbonate, which has escaped change. As the preparations of iron containing ferrous oxide are the most esteemed, the change which this precipitate undergoes has always been a matter of regret, and various attempts have been made to prevent it. Saccharine matter has been ascertained to possess the required preservative properties, and in the preparation under consideration it is used to prevent the ferrous carbonate as first precipitated from passing into the ferric hydroxide.

Becker, a German physician, was the first to suggest the use of saccharine matter as a means of protection against the absorption of oxygen, and the idea was carried out by Klauer, a German chemist, who first made the saccharated ferrous carbonate. The use of boiling distilled water in the process is to avoid the action of the air contained in unboiled water. The washed precipitate is pressed so as to free it from water as far as possible, and then incorporated with the sugar in fine powder. The mode of treating the precipitate unnecessarily exposes it to the action of the air, and the late London method of incorporating it with the sugar immediately after washing was on this account preferable. The final drying temperature should not exceed 54.5° C. (130° F.).

Properties.—"Saccharated Ferrous Carbonate is a greenish-brown powder, gradually becoming oxidized by contact with air; odorless, and having at first a sweetish, afterwards slightly ferruginous, taste. Saccharated Ferrous Carbonate is only partially soluble in water, but is completely dissolved on the addition of hydrochloric acid, with copious evolution of carbon dioxide, forming a clear, greenish-yellow liquid. Dissolve 1 Gm. of Saccharated Ferrous Carbonate in 5 mils of hydrochloric acid, and dilute the solution with distilled water until it measures 100 mils. Portions of this solution yield a blue precipitate with either potassium ferrocyanide T.S. or potassium ferricyanide T.S.; another 10 mil portion of the solution shows not more than a slight turbidity with barium chloride T.S. (*sulphate*).

"**Assay.**—Dissolve about 2 Gm. of Saccharated Ferrous Carbonate, accurately weighed, in 15 mils of diluted sulphuric acid, and dilute the solution with distilled water to about 100 mils. Titrate immediately with tenth-normal potassium dichromate V.S., potassium ferricyanide T.S being used as indicator. It shows not less than 15 per cent. of $FeCO_3$.

"Each mil of tenth-normal potassium dichromate V.S used corresponds to 0.011584 Gm. of $FeCO_3$. Each gramme of Saccharated Ferrous Carbonate corresponds to not less than 13 mils of tenth-normal potassium dichromate V.S." *U. S.*

"A greenish-brown powder, with a feebly chalybeate taste. Soluble with effervescence in *hydrochloric acid* diluted with half its volume of *water.* 1 gramme, dissolved in excess of warm *concentrated phosphoric acid* and diluted with *water,* does not cease to yield a blue precipitate with *solution of potassium ferricyanide* until 43.1 millilitres of *N/10 solution of potassium bichromate* have been added. *Arsenic limit* 5 parts per million." *Br.*

Saccharated ferrous carbonate is sometimes seen in small coherent lumps, usually of a grayish-brown color, permanent in the air, having a sweet, styptic taste, and wholly and readily soluble in warm hydrochloric acid, diluted with half its volume of water, with effervescence. The presence of ferric oxide is a defect, which is avoided in Vallet's ferruginous mass.

Uses.—This preparation is an excellent chalybeate, possessing the advantages of having nearly all the iron in it in the ferrous state, and of being readily soluble in acids. Originally introduced into the official list by the Edinburgh College, it appeared for the first time in the Dublin and London Pharmacopœias

of 1850 and 1851. It is undoubtedly more active than the ferric subcarbonate, and must be used in a smaller dose. It is, however, inferior to Vallet's ferruginous mass, in the preparation of which the anti-oxidizing influence of saccharine matter is much more fully applied.

Dose, of the saccharated ferrous carbonate, from five to fifteen grains (0.32–1.0 Gm.), given in pills.

FERRI CHLORIDUM. U. S.

FERRIC CHLORIDE Ferr. Chlor. [Iron Perchloride, Sesquichloride of Iron]

(fĕr'rī ȼhlō'rī-dŭm)

"It contains $FeCl_3$ (162.22) in a hydrated form corresponding to not less than 20 per cent. of Fe. Preserve it in well-closed glass containers." *U. S.*

Perchloride of Iron, Chloride of Iron; Ferrum Muriaticum Oxydatum, Chloridum vel Chloruretum Ferricum, Ferri Perchloridum; Chlorure ferrique, *Fr. Cod.*; Perchlorure de Fer, *Fr.*; Ferrum Sesquichloratum, *P. G.*; Eisenchlorid, *G.*; Cloruro ferrico, *Sp.*

The U. S. P. IX does not give a process for preparing ferric chloride; the U. S. P. VIII process is appended.

* "Solution of Ferric Chloride, *one hundred grammes* [or 3 ounces av., 231 grains], to make *forty grammes* [or 1 ounce av., 180 grains]. Evaporate the Solution of Ferric Chloride on a water-bath until it weighs *forty grammes* [or 1 ounce av., 180 grains]; then set it aside in a glass-covered vessel, until it forms a crystalline mass. Lastly, break the salt into pieces, and keep it in glass-stoppered bottles, protected from light." *U. S. VIII.*

The U. S. P. VIII did not give a process for making this salt directly from metallic iron, but simply evaporated the official solution of ferric chloride. The former U. S. P. directed a process which had been adopted with but little alteration from that of Wittstein. When iron is heated with hydrochloric acid, water is decomposed, the hydrogen escapes with effervescence, and the oxygen uniting with the iron forms ferrous oxide, which reacts with the hydrochloric acid to form water and ferrous chloride. The next step of the process is to convert the ferrous chloride into the ferric salt. This is effected by treating it with hydrochloric and nitric acids and heating until red fumes no longer escape. The following reaction explains this:

$$6FeCl_2 + 2HNO_3 + 6HCl = 6FeCl_3 + 2NO + 4H_2O$$

The solution is then evaporated, and, on cooling, concretes into a crystalline mass. The relative proportions of iron and the two acids are adjusted very nearly to the production of these results. There are two crystallized chlorides, one, $FeCl_3 + 3H_2O$, which is very deliquescent, the other, $FeCl_3 + 6H_2O$, which is less so, but which, when allowed to stand over sulphuric acid, liquefies and slowly deposits crystals of the first chloride, $FeCl_3 + 3H_2O$, losing half of its water of hydration.

Properties.—"Ferric Chloride occurs in orange-yellow, crystalline pieces, odorless, or with a faint odor of hydrochloric acid, and having a strongly styptic taste. It is very deliquescent in air. One Gm. of Ferric Chloride dissolves in 0.2 mil of water at 25° C. (77° F.); freely soluble in alcohol and soluble in glycerin or ether. At about 35.5° C. (95.9° F.) the salt fuses to a reddish-brown liquid. When strongly heated, it decomposes, losing some ferric chloride, water and hydrochloric acid, and leaving a residue of ferric oxide. An aqueous solution of Ferric Chloride, made by dissolving 10 Gm. of the salt in 15 mils of distilled water, responds to the tests for identity and purity under *Liquor Ferri Chloridi,* omitting the test for hydrochloric acid.

"**Assay.**—Dissolve about 1 Gm. of Ferric Chloride, accurately weighed in a stoppered weighing-bottle, in 25 mils of distilled water, add 3 mils of hydrochloric acid and 4 Gm. of potassium iodide, and allow the mixture to stand in a glass-stoppered flask or bottle for thirty minutes at a temperature of 40° C. (104° F.). Cool this solution, then dilute it with 100 mils of distilled water and titrate with tenth-normal sodium thiosulphate V.S., using starch T.S. as indicator. It shows not less than 20 per cent. of Fe.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Ferric Chloride corresponds to not less than 35.8 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

It contains a variable proportion of water according to the crystalline forms it is made to assume, having about 40 per cent., or six molecules, when in fine acicular crystals, and only 22 per cent., or two and a half molecules, when in the form of larger tables.

Syrup of Ferrous Chloride.—Dissolve 5 grammes of dry ferrous chloride in 20 grammes of orange-flower water, and add 800 grammes syrup of gum and 175 grammes syrup of orange-flower. (See *Syrupus Ferri Protochloridi,* N. F. IV, Part III.)

Pills of Ferrous Chloride.—Dry ferrous chloride, powdered marshmallow-root, each 10 grammes, mucilage sufficient. Make into 100 pills, which are to be silvered.

Syrupus Ferri Chloridi (Edel). *Syrup of Iron Chloride.*—Take of Solution of Chloride of Iron (U. S. P.), 208 minims; Potassium Citrate, 224 grains; Citric Acid, 60 grains; Water, 8 fluidounces; Glycerin, 5 fluidounces; Syrup, 16 fluidounces. Dissolve the potassium citrate and citric acid in the water, add the iron solution, and when the reaction ceases filter the solution, then add the glycerin and syrup. (*D. C.,* 1894, 246.)

Tasteless Iron Chloride is made by adding an alkaline citrate in solution to a solution of iron sesquichloride, in such proportion that there shall be two molecules of the former and three molecules of chlorine. Usually from 120 to 140 grains of citric acid saturated with sodium hy-

droxide, potassium hydroxide, or ammonium hydroxide are required for the preparation of an ounce of a tincture of corresponding strength to the official tincture. The addition should be made to the liquor, and the final solution must not contain more than 40 per cent. of alcohol. R. Rother affirms that these so-called salts are mere mixtures of iron citrate and iodide or chloride of the alkali used. (See *Tinctura Ferri Citro-Chloridi*, N. F., Part III.)

Ferric chloride is incompatible with alkalies and with iodides and bromides from which it liberates the halogen elements.

Uses.—Ferric chloride is used almost exclusively in the form of tincture or liquor, and in reference to its effect and application we refer to *Tinctura Ferri Chloridi* and *Liquor Ferri Chloridi*. Excepting deliquescence, it keeps without change. When used, it may be dissolved in water in such proportions as may be required. Six, three, two, and one and a half drachms to a fluidounce of water have been recommended, the stronger solutions being used in the treatment of *varices*, the weaker for injection into *aneurisms*, and for application to *bleeding surfaces*, etc. J. Z. Lawrence, of England, has used it as a styptic in a semi-deliquescent state, and found it extremely efficient. He keeps it in a bottle, in which it gradually deliquesces, and applies the thick liquid portion, with a brush of spun glass, to the bleeding surface.

Dose, one grain (0.065 Gm.).

FERRI ET AMMONII CITRAS. U. S., Br.

IRON AND AMMONIUM CITRATE Ferr. et Ammon. Cit. [Ammonio-Ferric Citrate, Soluble Ferric Citrate]

(fĕr′rī ĕt ăm-mō′nī-ī cī′trās)

"Ferric citrate rendered more readily soluble by the presence of ammonium citrate and containing not less than 16 per cent. nor more than 18 per cent. of Fe. Preserve it in well-closed containers, protected from light." *U. S.*

Citrate of Iron and Ammonia; Ferri et Ammoniæ Citras, *Br.* 1867; Ferrum Citricum Ammoniatum, Ferri Ammonio-Citras, Ferro-Ammonium Citricum; Ammonio-Citrate of Iron, Soluble Citrate of Iron; Citrate de Fer et d'Ammoniaque (de Fer ammoniacal), *Fr. Cod.*; Citrate Ferrique Ammoniacal, *Fr.*; Citronensaures Eisenoxyd-Ammonium (Ammoniak), Ferriammoniumcitrat, *G.*; Citrato ferricoammonico, *Sp.*

No process is given in the U. S. P. IX for Iron and Ammonium Citrate. The British Pharm., 1914, process is as follows: "Solution of Ferric Sulphate, 200 *millilitres;* Solution of Ammonia, 460 *millilitres*, or *a sufficient quantity;* Citric Acid, 80 *grammes;* Distilled Water, *a sufficient quantity*. Prepare ferric hydroxide as follows:—Mix three hundred and twenty millilitres of the Solution of Ammonia with eight hundred millilitres of Distilled Water; gradually add to this the Solution of Ferric Sulphate, previously diluted with eight hundred millilitres of Distilled Water; stir constantly and briskly, taking care that ammonia is, finally, in slight excess as indicated by the odor; set aside the mixture for two hours, stirring it occasionally; pour it on a calico filter; when the liquid has drained away, wash the precipitated ferric hydroxide with Distilled Water until free from sulphates. Dissolve the Citric Acid in its own weight of Distilled Water; warm the mixture on a water-bath; add the ferric hydroxide, previously well drained; stir them together until nearly the whole of the hydroxide has dissolved, or until the Citric Acid is saturated with ferric hydroxide (prepared, if necessary, from more of the Solution of Ferric Sulphate); let the solution cool; add one hundred and ten millilitres of Solution of Ammonia; filter through flannel, adding some Distilled Water if necessary, evaporate to the consistence of syrup, the presence of a very slight excess of ammonia being maintained; dry in thin layers on flat porcelain or glass plates at a temperature not exceeding 40° C. (104° F.); remove the dry flakes of Iron and Ammonium Citrate." *Br.*

In the U. S. Pharmacopœia, 1890, the process consisted simply in evaporating a mixture of solution of ferric citrate and ammonia water. In the British, ferric hydroxide is first precipitated from a solution of the ferric sulphate, then digested at a moderate heat with a solution of citric acid, and lastly neutralized by ammonia. It has, however, been found by E. R. Squibb that a heat above 82.1° C. (180° F.) acts injuriously in the preparation of the ferric citrate, and the boiling heat directed in the British Pharmacopœia of 1864 was, therefore, improper. (*A. J. P.*, xxvii, 297.) This error has been corrected in the present Br. Pharmacopœia, which directs that the salt should be dried at a heat not above 38° C. (100.4° F.). In the U. S., 1890, formula the ferric citrate was used already prepared, in the British it is prepared in the process. The solution should be concentrated to a syrupy consistence before being poured out on porcelain or glass to dry, and it is important that the heat employed in the concentration should not exceed that indicated. Like most of the scaled iron salts, this preparation is not a true chemical compound, the ammonia not being in the proportion to form a double salt.

J. U. Lloyd (*N. R.*, 1879, 323) states that it is usually difficult to adjust accurately the quantity of the ammonia in this process, and proposes to use a definite quantity of a fixed salt, like ammonium citrate, instead. Thus: Prepare a solution of ammonium citrate from citric acid, 8 oz. av., and ammonia water q. s. Add the ammonia water to the citric acid until in slight excess, then evaporate the solution until it measures sixteen fluidounces. Then take of solution of iron tersulphate 16 fluidounces; citric acid 4 ounces av.; distilled water and ammonia water, each, a sufficient quantity; solution of ammonium citrate 5 fluidounces. Prepare hydrated ferric oxide from the solution of iron tersulphate. Having drained it, place in an evaporating dish and add the citric acid, warm upon a steam or water bath, and stir until the citric

acid is dissolved, then add the solution of ammonium citrate and stir until the hydrated oxide is dissolved, filter and evaporate to the consistence of thick syrup, spread upon glass with a brush, and dry. The yield will be 4234 grains.

R. Rother recommends the following method: Dissolve 272 parts of ferric citrate in three or four times its weight of water with heat, add 79 parts of ammonium carbonate, evaporate, and scale in the usual manner. (*A. J. P.*, 1887, p. 166.)

Properties.—Iron and ammonium citrate is more soluble than the ferric citrate. It is in "thin, transparent, garnet-red scales, odorless and having a saline, mildly ferruginous taste. It is deliquescent in moist air. Iron and Ammonium Citrate is readily and completely soluble in water; insoluble in alcohol. An aqueous solution (1 in 20) is neutral or but slightly acid or alkaline to litmus. When strongly heated, it chars, and finally leaves a residue of ferric oxide. Heat Iron and Ammonium Citrate with potassium hydroxide T.S.; it yields a brownish-red precipitate, and ammonia is evolved. Ammonia water, added to an aqueous solution, produces no precipitate, but darkens the solution. Remove the iron from 10 mils of an aqueous solution of Iron and Ammonium Citrate (1 in 10) by boiling it with an excess of potassium hydroxide T.S., filter, and then slightly acidulate the filtrate with acetic acid. A portion of the cooled filtrate, when mixed with 2 mils of calcium chloride T.S., and again heated to boiling, gradually deposits a white crystalline precipitate. Another portion of the filtrate, when acidulated more strongly with acetic acid and allowed to stand for twenty-four hours, does not yield a white crystalline precipitate (*tartrate*). An aqueous solution of Iron and Ammonium Citrate (1 in 100) does not yield a blue precipitate with potassium ferrocyanide T.S. unless it is acidulated with hydrochloric acid (difference from *ferric citrate*).

"**Assay.**—Dissolve about 1 Gm. of Iron and Ammonium Citrate, accurately weighed, in 25 mils of distilled water and 7 mils of hydrochloric acid, in a glass-stoppered flask or bottle, add 4 Gm. of potassium iodide, stopper the bottle securely and keep it at a temperature of 40° C. (104° F.) for thirty minutes. Then cool, and titrate with tenth-normal sodium thiosulphate V.S., using starch T.S. as indicator. It shows not less than 16 per cent. nor more than 18 per cent. of Fe.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Iron and Ammonium Citrate corresponds to not less than 28.6 mils nor more than 32.2 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

"In thin, dark red, transparent scales. Taste slightly sweet and astringent. Soluble in 0.5 part of *water;* almost insoluble in *alcohol* (90 per cent.). Aqueous solution slightly acid to *litmus.* Yields from 31 to 32 per cent. of ash, which, when moistened with *water,* is not alkaline to *litmus* (absence of fixed alkali). When a solution of 1 gramme in 10 millilitres of *water* is heated with a slight excess of *solution of potassium hydroxide,* ammonia is evolved and ferric hydroxide is precipitated; the filtrate from this, acidified with *acetic acid,* does not yield any crystalline precipitate (absence of tartrates). Yields not more than the slightest characteristic *reaction* for sulphates. *Arsenic limit* 5 parts per million." *Br.*

Its precise chemical constitution is not determined; but Méhu (*Jahresb.*, 1873, 570), on evaporating a solution of ferrous citrate in ammonia to dryness, obtained a salt of the formula $Fe_2(NH_4)_2.(C_6H_5O_7)_2 + 3H_2O$.

Uses.—This salt is a pleasant chalybeate, in doses of five grains (0.32 Gm.). According to Paris, it may be mixed with the carbonated alkalies without decomposition, and given in a state of effervescence with citric acid. It should be prescribed only in solution, as it is not suited for administration in the form of pills, owing to the presence of ammonia, which renders it too soluble, and causes the pills to flatten after they have been made, and frequently to cohere in one solid mass. The official ferric citrate should always be used for pills, as it is more slowly dissolved.

Dose, from three to eight grains (0.2–0.5 Gm.).

Off. Prep.—Vinum Ferri Citratis, *Br.;* Vinum Carnis et Ferri, *N. F.;* Vinum Ferri, *N. F.*

FERRI ET POTASSII TARTRAS. Br.

IRON AND POTASSIUM TARTRATE

(fĕr'rī ĕt pǫ-tăs'sĭ-ī tăr'trăs)

Ferrum Tartaratum, *Br.;* Tartarated Iron; Potassio-Ferric Tartrate; Ferri Potassio-Tartras, Ferrum Tartarizatum, Tartras Ferrico-Potassicus, s. Potassico-Ferricus, s. Ferrico-Kalicus, Ferri-Kalium Tartaricum; Tartarated (tartarized) Iron, Ferro-Tartrate of Potassium; Tartrate Ferrico-potassique, *Fr. Cod.;* Tartrate de Fer et de Potasse, Tartare Chalybé, Tartre martial, *Fr.;* Kaliumferritartrat, Weinsäures Eisenoxyd-Kali, Eisenweinstein, *G.;* Tartrato ferrico-potasico, *It.;* Tartrato ferrico-potasico, *Sp.*

The U. S. P. IX does not recognize this salt; the process of the 1890 Pharmacopœia will be found in the *U. S. Dispensatory,* 19th edition, page 499. The rubric requirement of the U. S. P. VIII is as follows: "It should contain Iron and Potassium Tartrate corresponding in amount to not less than 15 per cent. of metallic iron, and should be kept in well-stoppered bottles, protected from light." *U. S. VIII.*

The British process is as follows: "Solution of Ferric Sulphate, 200.0 *millilitres;* Solution of Ammonia, 320.0 *millilitres,* or *a sufficient quantity;* Acid Potassium Tartrate in powder, 66.5 *grammes;* Distilled Water, *a sufficient quantity.* From the Solution of Ferric Sulphate prepare ferric hydroxide as directed under 'Ferri et Ammonii Citras,' page 465. Mix the ferric hydroxide intimately with the Acid Potassium Tartrate in a porcelain dish; let the mixture stand for twenty-four hours; heat to a temperature not exceeding 60° C. (140° F.), add gradually six hundred *millilitres* of Distilled Water;

stir constantly until nothing more will dissolve; filter; evaporate at a temperature not exceeding 60° C. (140° F.) to the consistence of syrup; dry in thin layers on flat porcelain or glass plates at a temperature not exceeding 40° C. (104° F.); remove the dry flakes of Iron and Potassium Tartrate." *Br.*

The object of this process was to combine the excess of acid in the potassium bitartrate with ferric hydroxide. The plan of Soubeiran in the main was adopted—namely, that of dissolving the moist ferric hydroxide to saturation in a mixture of the bitartrate and water, aided by a moderate heat. The oxide is obtained from the solution of ferric sulphate, which is precipitated by ammonia. Potassium hydroxide, which was used in the former British process, is not a good precipitant, because the alkali adheres obstinately to the precipitated oxide, and cannot be completely separated even by repeated washings. The oxide should be gradually added to the bitartrate and water, heated to 60° C. (140° F.), as recommended by Soubeiran, at which temperature the oxide dissolves more readily and in larger quantity than when a higher temperature is employed. Besides, in the latter case, a portion of the ferric oxide is converted into ferrous oxide. In the U. S., 1890, process the addition of ammonia water to the cooled filtrate dissolves the precipitated insoluble ferric tartrate, and is in accordance with the recommendation of J. U. Lloyd, who asserts that this modification renders the salt more soluble without interfering with its stability. G. H. Chas. Klie suggested this improvement in *A. J. P.*, 1876, p. 170. (See also *N. R.*, 1878, p. 21.) In both formulas the liquid is poured out on a plane surface so as to dry in scales. When duly carried into effect, they yield a product at all times identical, and having all the required qualities of the salt. W. Lyon (*P. J.*, 1902, 530) proposes to substitute potassium and sodium tartrate for the acid potassium tartrate used in the British Pharm. process, believing that the resulting scaled salt will retain its ready solubility for a much longer time than will the official preparation; he uses the following proportions: Solution of ferric sulphate 300 mils; solution of ammonia 480 mils or a sufficient quantity; potassium and sodium tartrate 176 Gm. The official process and directions are otherwise followed. For Roger's process for this salt and the manufacture of *Boules de Mars* (balls of iron and potassium tartrate), see *U. S. D.*, 17th ed., 611.

Ure proposed *ferrous tartrate* for medicinal use. He made it by acting on clean iron filings, or bits of iron wire, with a solution of tartaric acid. It is a pulverulent salt, insoluble in water, and possessing a mild chalybeate taste.

Properties.—Iron and potassium tartrate, according to the U. S. P. VIII, is in "thin, transparent scales, varying in color from garnet-red to reddish-brown, without odor, and having a sweetish, ferruginous taste; slightly deliquescent in the air. Very soluble in water; insoluble in alcohol. When strongly heated, the salt chars, emits fumes having an odor resembling that of burning sugar, and finally leaves a dark brown residue, having a strongly alkaline reaction, and effervescing with acids (distinction from *iron and ammonium tartrate*). An aqueous solution of Iron and Potassium Tartrate should be neutral to litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide T.S. the solution does not afford a blue color or precipitate, unless it be acidulated with hydrochloric acid. When heated with potassium hydroxide T.S., the salt yields a brownish-red precipitate. If an aqueous solution of the salt (1 in 10) be deprived of its iron by boiling with an excess of potassium hydroxide T.S., the filtrate, when slightly acidulated with acetic acid, will gradually deposit a white, crystalline precipitate. If 0.555 Gm. of the dry salt be dissolved in 15 Cc. of water and 2 Cc. of hydrochloric acid, in a glass-stoppered flask having a capacity of about 100 Cc., and if, after the addition of 1 Gm. of potassium iodide, and securely closing the flask, the mixture be kept for half an hour at 40° C. (104° F.), and then cooled, it should require not less than 15 Cc. of tenth-normal sodium thiosulphate V.S. to discharge the color of the liquid, starch T.S. being used as indicator (each Cc. of tenth-normal sodium thiosulphate V.S. indicating 1 percent. of metallic iron)." *U. S. VIII.*

"In thin transparent scales of a deep garnet color; taste somewhat sweetish and astringent. Soluble in *water,* sparingly soluble in *alcohol* (90 per cent.). *Arsenic limit* 5 parts per million. The aqueous solution, acidified with *hydrochloric acid,* yields a copious blue precipitate with *solution of potassium ferrocyanide.* When a solution of 1 gramme in 10 millilitres of *water* is boiled with a slight excess of *solution of potassium hydroxide,* a reddish-brown precipitate separates, and the filtered solution, slightly acidified with *acetic acid,* yields, as it cools, a crystalline deposit. Yields not less than 30 per cent. of ferric oxide when incinerated with free access of air, the ash being washed with *water* and again incinerated." *Br.*

According to the view of its nature taken in the U. S. Pharmacopœia VIII, it is a double salt, consisting of one molecule of ferric tartrate and one of potassium tartrate:

$$Fe_2(C_4H_4O_6)_3 + K_2C_4H_4O_6 + H_2O$$

Flückiger (*Pharmaceutische Chemie,* 2d ed., 573, 188), on the other hand, considers the salt formed to be one in which Fe_2O_2 is present as a bivalent group, and gives it the formula:

$$C_4H_4O_6K_2 + C_4H_4O_6(Fe_2O_2) + 4H_2O$$

The salt is incompatible with astringent vegetable infusions, which give rise to a dark-colored precipitate.

Uses.—Iron and potassium tartrate is a mild, agreeable chalybeate, with but little astringency. It is well borne by the stomach, taken fasting or with the food. Its slight taste and ready

solubility make it one of the best ferruginous preparations for children.

Dose, for an adult, five to ten grains (0.32–0.65 Gm.), given preferably in solution.

FERRI ET QUININÆ CITRAS. U. S., Br.

IRON AND QUININE CITRATE Ferr. et Quin. Cit. [Ferri et Quininæ Citras Solubilis, U. S. P. VIII, Soluble Iron and Quinine Citrate]

(fĕr'ri ĕt quĭ-nī'næ cī'trăs)

"Iron citrate and quinine citrate rendered more soluble by the presence of ammonium citrate and containing not less than 11.5 per cent. of anhydrous quinine ($C_{20}H_{24}O_2N_2$) and not less than 13 per cent. of Fe. Preserve it in amber-colored, well-stoppered bottles, protected from light." *U. S.*

Ferri et Quiniæ Citras, *Br.* 1867, *U. S.* 1870; Citrate of Iron and Quinia; Citrate de Fer et de Quinine, *Fr.*; Chininum Ferro-Citricum, *P. G.*; Eisenchinincitrat, Citronensaures Eisen-Chinin, *G.*

The U. S. P. VIII contained two forms of iron and quinine citrate, one of which had the word "Solubilis" in the title; the U. S. P. IX abandoned the use of this word and dropped the less soluble compound entirely, retaining the soluble form under the title "Ferri et Quininæ Citras," which now corresponds with the same preparation of the British Pharm., 1914.

"Solution of Ferric Sulphate, 180 *millilitres;* Quinine Sulphate, 40 *grammes;* Diluted Sulphuric Acid, 60 *millilitres;* Citric Acid, 123 *grammes;* Solution of Ammonia, Distilled Water, of each, *a sufficient quantity.* From the Solution of Ferric Sulphate prepare ferric hydroxide as directed under 'Ferri et Ammonii Citras,' page 465. Mix the Quinine Sulphate with eight times its weight of Distilled Water; add the Diluted Sulphuric Acid; when the salt is dissolved precipitate the quinine with a slight excess of Solution of Ammonia; collect the precipitate on a filter; wash it with twelve hundred *millilitres* of Distilled Water. Dissolve the Citric Acid in its own weight of Distilled Water; warm the solution on a water-bath; add the ferric hydroxide, previously well drained; stir them together; when the hydroxide has dissolved, add the precipitated quinine; continue the stirring until this also has dissolved; let the solution cool; add, in small quantities at a time, sixty *millilitres* of Solution of Ammonia, diluted with eighty *millilitres* of Distilled Water; stir briskly, allowing the quinine which separates with each addition of ammonia to dissolve before the next addition is made; filter the solution; evaporate it to the consistence of a thin syrup; dry the latter in thin layers on flat porcelain or glass plates at a temperature not exceeding 40° C. (104° F.); remove the dry flakes of Iron and Quinine Citrate." *Br.*

The U. S. P. IX does not contain a process for soluble iron and quinine citrate; the U. S. P., 1890, process was as follows: "Ferric Citrate, *eighty-five grammes* [or 2 ounces av., 436 grains]; Quinine, dried at 100° C. (212° F.) to a constant weight, *twelve grammes* [or 186 grains]; Citric Acid, *three grammes* [or 46 grains]; Ammonia Water, Distilled Water, each, *a sufficient quantity,* to make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Ferric Citrate in *one hundred and sixty cubic centimeters* [or 5 fluidounces, 197 minims] of Distilled Water, by heating on a water-bath at a temperature not exceeding 60° C. (140° F.). To this solution add the Quinine and Citric Acid previously triturated with *twenty cubic centimeters* [or 325 minims] of Distilled Water, and stir constantly until the Quinine and Citric Acid are dissolved. Then add gradually, and with constant stirring, *fifty cubic centimeters* [or 1 fluidounce, 331 minims], or *a sufficient quantity,* of Ammonia Water, so that, after the addition of each portion of the latter, the precipitated Quinine will be redissolved and the liquid acquire a greenish-yellow tint. Lastly, evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.*, 1890.

This official preparation was first added to the list in 1890, in answer to a demand which was very persistent. The iron and quinine citrate formerly official was comparatively insoluble and better adapted for use in pills; but the combination of iron, quinine, and citric acid is wanted more frequently in solution, and hence a salt which can be quickly dissolved is necessary.

The use of ferrous sulphate by the former British process was abandoned, and the solution of ferric sulphate retained. From this the freshly precipitated ferric hydroxide is obtained by precipitation with ammonia. The next step is to separate quinine from the sulphate, by simply dissolving the salt in water with the aid of sulphuric acid, and then precipitating by ammonia. Thirdly, the hydroxide and quinine are dissolved successively, aided by the heat of a water bath, in solution of citric acid, whereby an iron and quinine citrate is obtained. The ammonia is added in order to render the iron and quinine citrate more soluble by the agency of a portion of ammonium citrate. It is important that the ammonia should not be added in excess; on the contrary, the solution should retain a slight acid reaction. (Fleurot.) After evaporation, the salt is dried, as in the other process, on glass or porcelain, so as to be obtained in thin scales.

No analysis has been made that determines precisely the chemical composition of this "scaled salt." It is undoubtedly a mere mixture of the iron and quinine citrates, containing ammonium citrate.

Owing to the comparative cheapness of the alkaloid quinine at the present time the tendency to substitute other cinchona alkaloids has greatly diminished, and the introduction of an

official assay process furnishes an excellent check to these practices.

Amorphous quinine or chinoidine was sometimes substituted for the crystallizable alkaloid. For the detection of this fraud, de Vrij proposed a method which depended upon the fact that oxalic acid forms with crystallizable quinine, in a chloroformic solution, white crystals of quinine oxalate without discoloration. (See *N. R.*, 1881, 10.)

When dissolved by the aid of an acid, it forms a solution which, decolorized by a little purified animal charcoal, turns the plane of polarization strongly to the left—a character of quinine, cinchonine turning it to the right. (Squire.) The salt is said to be sometimes adulterated by cinchonine, which would be at once detected by the test of solubility in ether and the effect on polarized light, above given. Oscar Zinn (*A. J. P.*, 1877, 550), examined six commercial samples, two of which contained no quinine, but cinchonine. H. G. Drueding found three out of six samples deficient in quinine. As it occurs in the British market, it is of exceedingly variable composition, containing, according to J. C. Braithwaite, who examined thirty-five different specimens, a proportion of quinine varying from 1.5 to 17 per cent. (*P. J.*, 1868, 157.) The proportion of alkaloid appears to be usually below the standard. (A. W. Gerrard, *P. J.*, March, 1873, 763.) According to C. H. Wood (*P. J.*, 2d ser., x, 644), this salt undergoes a rapid change of composition when exposed to the influence of the direct rays of the sun.

The official process of assay will doubtless bring to light all shortcomings. (See results of examination of commercial iron and quinine citrate by E. C. Federer, *Proc. Mich. Pharm. Assoc.*, 1887, or *Ph. Era*, 1887, p. 357.)

Properties.—The U. S. Pharmacopœia IX describes it as in "thin, transparent scales, of a greenish or golden-yellow color, odorless, and having a bitter, mildly ferruginous taste. It is deliquescent. Iron and Quinine Citrate is rapidly and completely soluble in cold water, partly soluble in alcohol. An aqueous solution (1 in 10) is acid to litmus. When strongly heated, Iron and Quinine Citrate chars, and finally leaves a residue of ferric oxide. When heated with potassium hydroxide T.S., a brown precipitate is produced and ammonia is evolved. On the addition of a slight excess of ammonia water to an aqueous solution of Iron and Quinine Citrate (1 in 10), the color of the liquid is deepened, and a white, curdy precipitate is produced. A portion of the filtrate from this precipitate does not yield a blue color or precipitate with potassium ferrocyanide T.S. unless it is acidulated with hydrochloric acid. Boil an aqueous solution of Iron and Quinine Citrate (1 in 10) with an excess of potassium hydroxide T.S. until completely precipitated, and slightly acidulate the filtrate with acetic acid. A portion of the cooled filtrate, mixed with 2 mils of calcium chloride T.S. and again heated to boiling, gradually deposits a white, crystalline precipitate. Another portion of the filtrate, more strongly acidulated with acetic acid and allowed to stand for twenty-four hours, does not yield a white, crystalline precipitate (*tartrate*).

"**Assay for Quinine.**—Dissolve about 1 Gm. of Iron and Quinine Citrate, accurately weighed, in 20 mils of distilled water in a separator, add 5 mils of ammonia water and 10 mils of chloroform, and shake the separator for one minute. Allow the liquids to separate, draw off the chloroform layer through a small filter moistened with chloroform, into a tared dish, and shake the residuary liquid a second and a third time with portions of 10 mils each of chloroform, passing the chloroform through the filter each time and finally washing the filter with 5 mils of chloroform. Evaporate the combined chloroform solutions, redissolve the residue in 3 mils of alcohol, again evaporate and then dry the residue to constant weight at 100° C. (212° F.). This residue corresponds to not less than 11.5 per cent. of the amount of Iron and Quinine Citrate taken for the assay and conforms to the identity tests under *Quinina*.

"**Assay for Iron.**—Heat the aqueous liquid, from which the quinine has been removed in the manner just described, on a water bath, until the odors of chloroform and of ammonia have disappeared, allow to cool and dilute with distilled water to a volume of 25 mils. Transfer the liquid to a glass-stoppered bottle, add 15 mils of hydrochloric acid and 3 Gm. of potassium iodide, and, after securely closing the bottle, allow the mixture to stand for thirty minutes at 40° C. (104° F.). Then cool and titrate with sodium thiosulphate V.S., using starch T.S. as indicator. It shows not less than 13 per cent. of Fe.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Iron and Quinine Citrate corresponds to not less than 23.3 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

The British Pharm., 1914, describes it as "in thin scales of a greenish-yellow color, somewhat deliquescent; taste bitter, chalybeate. Soluble in 0.5 part of *water*. The solution is very slightly acid, and yields precipitates which are reddish-brown with *solution of potassium hydroxide*, white with *solution of ammonia*, blue with *solution of potassium ferrocyanide*, and with *solution of potassium ferricyanide*. *Arsenic limit* 5 parts per million. Ash, when moistened with *water*, not alkaline to *litmus* (absence of fixed alkali). 5 grammes, dissolved in 45 millilitres of *water* and treated with excess of *solution of ammonia*, yield a white precipitate, which, when dissolved out by repeated treatment of the liquid with *chloroform*, the latter evaporated, and the residue dried at 110° C. (230° F.), weighs not less than 0.75 gramme. This precipitate is almost entirely soluble in a little *ether;* on incineration it leaves not more than a minute residue; neutralised with *diluted*

sulphuric acid and crystallised, it possesses the characters of and responds to the tests described under 'Quininæ Sulphas.'" *Br.*

See modification of process by F. A. Sieker (*Ph. Rund.*, 1895, 36).

Uses.—Preparations of this character are therapeutically irrational; if the hematinic effects of iron and the tonic action of quinine are desired simultaneously, it is far better to compose an extemporaneous mixture in which the proportion of each shall be regulated to the needs of the individual patient than resort to a fixed combination. Each five grains (0.3 Gm.) of the salt represents approximately one-half grain (0.032 Gm.) of quinine and two-thirds of a grain (0.036 Gm.) of iron.

Dose, five to ten grains (0.32–0.65 Gm.).

Off. Prep.—Vinum Ferri Amarum, *N. F.*

FERRI HYDROXIDUM CUM MAGNESII OXIDO. U. S.

FERRIC HYDROXIDE WITH MAGNESIUM OXIDE Ferr. Hydrox. cum Mag. Oxid.

(fĕr'rī hȳ-drŏx'ĭ-dŭm cŭm măg-nē'şī-ī ŏx'ĭ-dō)

Ferri Oxidum Hydratum cum Magnesia, *U. S.* 1890, Arsenic Antidote, Ferric Hydrate with Magnesia; Antidotum Arsenici; Antidote to Arsenious Acid; Hydrated Oxide of Iron with Magnesia; Contre-poison de l'arsenic, *Fr.*; Gegengift des Arseniks, Gegengift der Arsenigensaure, *G.*; Hidrato ferrico magnesico, *Sp.*

* "Solution of Ferric Sulphate, *forty millilitres* [or 1 fluidounce, 169 minims]; Magnesium Oxide, *ten grammes* [or 154 grains]; Water, *a sufficient quantity.* Mix the solution of ferric sulphate with *one hundred and twenty-five mils* [or 4 fluidounces, 109 minims] of water, and keep the liquid in a large, well-stoppered bottle. Rub the magnesium oxide with cold water to a smooth and thin mixture, transfer this to a bottle capable of holding about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] fill it with water to about three-fourths of its capacity, and keep it tightly stoppered. When the preparation is wanted for use, shake the magnesium oxide mixture until of a thin, creamy consistence, slowly add to it the diluted solution of ferric sulphate, and shake them together until a uniformly smooth mixture results.

"NOTE.—In this process the 10 Gm. [or 154 grains] of magnesium oxide may be replaced by 300 mils [or 10 fluidounces, 69 minims] of magnesia magma, diluting it with sufficient water to make the required volume.

"Always keep the diluted solution of ferric sulphate and the magnesia mixture on hand in separate bottles, ready for immediate use, so that the antidote may be quickly prepared." *U. S*

Ferric hydroxide was dropped from the U. S. P. IX and ferric hydroxide with magnesium oxide retained. This is a preparation which has been introduced for the purpose of furnishing a ready and efficient antidote against arsenic trioxide or arsenous acid. It is almost identical with the *Antidotum Arsenici* of the German Pharmacopœia, and experience has shown its effectiveness. Ferric hydroxide is produced when to the mixture of magnesia is added the diluted solution of ferric sulphate, and, as the magnesia is in excess and acidity thus prevented, no harm can result from not separating the by-products of the reaction. When mixed as officially directed, and ready for use, it contains ferric hydroxide with magnesium sulphate and hydroxide. It has been shown that no soluble compound with arsenic is formed when it is used as an antidote, and the presence of the magnesium salt, from a therapeutical point of view, is not at all objectionable. (See *Arseni Trioxidum,* p. 195.)

Dose, four fluidounces (120 mils).

FERRI PHOSPHAS. U. S.

FERRIC PHOSPHATE Ferr. Phos. [Ferri Phosphas Solubilis, U.S. VIII, Soluble Ferric Phosphate]

(fĕr'rī phŏs'phās)

"Ferric Phosphate rendered soluble by the presence of sodium citrate. It contains not less than 12 per cent. of Fe. Preserve it in amber-colored, well-stoppered bottles, protected from light." *U. S.*

Ferri et Sodii Citro-phosphas; Ferrum Phosphoricum cum Natrio Citrico; Soluble Phosphate of Iron, Sodio-ferric Citrophosphate; Citro-phosphate de Fer et de Soude, *Fr.*; Natriumferricitro-phosphat, *G.*

This compound must not be confused with the iron phosphate official in the former U. S. and British Pharmacopœias which was an insoluble slate-colored powder. The word "solubilis" was dropped in the title of the U. S. P. IX, and this compound is in thin bright green scales, and the old slate-colored powder is no longer official. (See *Ferri Phosphas Saccharatus.*)

No process is given for this preparation in the U. S. P. IX. That of the U. S. P., 1890, is as follows: "Ferric Citrate, *fifty grammes* [or 1 ounce av., 334 grains]; Sodium Phosphate, unefflouresced, *fifty-five grammes* [or 1 ounce av., 411 grains]; Distilled Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Dissolve the Ferric Citrate in the Distilled Water by heating on a water-bath. To this solution add the Sodium Phosphate, and stir constantly until it is dissolved. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark amber-colored, well-stoppered bottles." *U. S.*, 1890. (See preceding article.)

W. A. Puckner (*Proc. A. Ph. A.*, 1897, 231) proposes the following process, preferring potassium chlorate to nitric acid as an oxidizing agent.

Ferrous sulphate, in clear crystals, 156 Gm.; sulphuric acid, 20 mils; potassium chlorate, 12 Gm.; ammonia water, 340 mils; citric acid, 120 Gm.; sodium phosphate, unefflouresced, 200 Gm.; water, a sufficient quantity. Add the sulphuric acid to 240 mils of water, contained in a glass or porcelain vessel, to this add the ferrous sulphate, warm gently until all is dissolved, then

add the potassium chlorate and continue the heat for one-half hour, or until a drop of the solution added to potassium ferricyanide test solution no longer produces a distinct green or bluish-green color. Add this solution, slowly and with constant agitation, to the ammonia water contained in a suitable vessel; to this mixture add hot water, 4000 mils, and allow to subside, and, after one-half hour, decant or siphon off the clear supernatant liquid. To the residue add 2000 mils of hot water, allow to subside, and decant; repeat this washing with six portions of hot water, allowing the last portion to subside for at least six hours or over night. Decant or siphon off the clear liquid as closely as possible, then add to the remaining magma the citric acid and the sodium phosphate, warm gently until solution results, and then evaporate on a water bath at a temperature not exceeding 60° C. (140° F.) until the solution weighs 500 Gm., and spread it on plates of glass, so that, when dry, the salt may be obtained in scales.

Solution of Ferric Phosphate (50 per cent.).—By evaporating the solution made by Puckner's method (see above) on a water bath until it measures 500 mils, a solution is made containing 50 per cent. of ferric phosphate.

Properties.—It is officially described as in "thin, bright green, transparent scales, without odor, and having an acidulous, slightly saline taste. The salt is permanent in dry air when excluded from light, but when unprotected, soon becomes discolored. Ferric Phosphate is freely and completely soluble in water; insoluble in alcohol. An aqueous solution of Ferric Phosphate (1 in 10) is slightly acid to litmus. The addition of ammonia water to an aqueous solution of Ferric Phosphate gives a reddish-brown color, but does not produce a precipitate. Ferric Phosphate, when boiled with potassium hydroxide T.S., produces a brownish-red precipitate without evolving ammonia. Boil an aqueous solution of Ferric Phosphate (1 in 10) with an excess of potassium hydroxide T.S. until deprived of its iron, strongly acidulate the filtrate with hydrochloric acid and cool a portion of the liquid. When mixed with an equal volume of magnesia mixture T.S., followed by a slight excess of ammonia water, this liquid affords an abundant, white, crystalline precipitate. This precipitate turns yellow when washed and treated with a few drops of silver nitrate T.S. (distinction from *pyrophosphate*).

"**Assay.**—Dissolve about 1 Gm. of Ferric Phosphate, accurately weighed, in 25 mils of distilled water, and 15 mils of hydrochloric acid in a glass-stoppered bottle, then add 3 Gm. of potassium iodide, securely stopper the bottle, keep it at a temperature of 40° C. (104° F.) for thirty minutes, then cool and titrate with tenth-normal sodium thiosulphate V.S., using starch T.S. as indicator. It shows not less than 12 per cent. of Fe.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Ferric Phosphate corresponds to not less than 21.5 mils of tenth-normal sodium thiosulphate V. S." *U. S.*

Uses.—Ferric phosphate is one of the best preparations to use when it is desired to exhibit iron in solution. It is as free from astringency as any of the official salts of iron, has little tendency to disturb the digestion and is an active chalybeate.

The *dose* is from five to ten grains (0.32–0.65 Gm.).

FERRI PHOSPHAS SACCHARATUS. Br.

SACCHARATED IRON PHOSPHATE

(fĕr'rī phŏs'phăs săc'ȼha-rā-tŭs)

"Saccharated Iron Phosphate is ferrous phosphate, more or less oxidised, mixed with glucose. It contains not less than 60 per cent. of ferrous salts calculated as ferrous phosphate, $Fe_3(PO_4)_2,8H_2O$." *Br.*

This preparation was introduced into the British Pharmacopœia, 1914, to replace the former "Ferri Phosphas" which was an insoluble slate-colored powder. The process is as follows: "Ferrous Sulphate, 120 *grammes;* Sodium Phosphate, 110 *grammes;* Sodium Carbonate, 50 *grammes;* Glucose, 40 *grammes;* Distilled Water, boiling, *a sufficient quantity.* Dissolve twenty *grammes* of the Glucose in four hundred *millilitres* of the Distilled Water, and dissolve the Ferrous Sulphate in the solution. Dissolve the Sodium Phosphate in four hundred *millilitres* of the Distilled Water, and to this add the solution of the Ferrous Sulphate, stirring constantly. Then add the Sodium Carbonate previously dissolved in four hundred *millilitres* of the Distilled Water. Mix thoroughly, and allow the precipitate to subside. Decant the supernatant liquid, wash the precipitate with two successive quantities, each of two thousand *millilitres* of the Distilled Water, mix it with the remainder of the Glucose, and dry at a temperature not exceeding 100° C. (212° F.). Powder the product and preserve it in a stoppered bottle. A slate-blue, amorphous powder. Taste sweetish, chalybeate. Partially soluble in *water,* soluble in *hydrochloric acid.* The acid solution yields blue precipitates with *solution of potassium ferrocyanide* and *solution of potassium ferricyanide;* when treated with *tartaric acid* and excess of *solution of ammonia,* and subsequently with *solution of magnesium ammonio-sulphate,* it yields a white granular precipitate. 1 gramme dissolved in excess of warm *concentrated phosphoric acid* does not cease to yield a blue precipitate with *solution of potassium ferricyanide* until 35.9 millilitres of *N/10 solution of potassium bichromate* have been added. *Arsenic limit* 5 parts per million." *Br.*

Glucose is used to protect the ferrous phosphate from oxidation, which it does only partially. This iron phosphate must not be confounded with the soluble ferric phosphate of the U. S. P. IX, which is in green transparent scales. As obtained by the present process, this U. S. preparation is not a definite chemical compound, but a mixture, which should probably be called sodio-ferric citro-phosphate, and bears a resemblance to the pyrophosphate, which is now usually made by a similar process. (See *Ferri Phosphas.*)

The British iron phosphate, 1898, was a very different salt. By double decomposition ferrous phosphate and sodium sulphate are produced, the former precipitating as a white bulky powder, which soon changes on exposure to a greenish-blue, and ultimately to a slate color; since the sodium phosphate is chemically an acid salt (Na_2HPO_4) a portion of phosphoric acid is liberated during the reaction, and this, retaining in solution some of the ferrous phosphate, requires the addition of the solution of sodium bicarbonate to neutralize it and set free the remainder of the ferrous phosphate. This salt, when first formed, is represented by the formula $Fe_3(PO_4)_2$; but its strong affinity for oxygen causes the gradual production of a sesquisalt, which, therefore, to a certain extent, always exists in the preparation; hence the former British authority required it to contain at least 47 per cent. of ferrous phosphate, $Fe_3(PO_4)_2.8H_2O$.

Ferric phosphate, dissolved to saturation in a boiling solution of metaphosphoric acid (HPO_3), under the name of *superphosphate of iron*, was proposed as a remedy, in 1851, by Routh, of London. Thomas Greenish of the same city, states that the solution of the salt, on cooling, hardens into a mass of pilular consistence, soluble in water in all proportions, and free from any disagreeable or inky taste.

Uses.—Ferric phosphate possesses the general properties of the ferruginous preparations, and has been given with advantage in *amenorrhea* and *dyspepsia.*

Dose, from five to ten grains (0.32–0.65 Gm.).

FERRI SULPHAS. U. S., Br.

FERROUS SULPHATE Ferr. Sulph. [Iron Protosulphate]

(fĕr'rī sŭl'phăs)

"It contains not less than 54.36 nor more than 57.07 per cent. of anhydrous ferrous sulphate, corresponding to about 99.5 per cent. of the crystallized salt [$FeSO_4 + 7H_2O = 278.02$]. Preserve it in well-closed containers." *U. S.*

"Ferrous Sulphate may be prepared by the interaction of diluted sulphuric acid and iron. It contains not less than 97.5 per cent. of pure ferrous sulphate, $FeSO_4,7H_2O$." *Br.*

Sulphate of Iron, Green Vitriol, Iron Vitriol, Sulfas Ferrosus, Ferrum Vitriolatum Purum, Vitriolum Martis Purum; Sulfate Ferreux Officinal, *Fr. Cod.;* Sulfate (protosulfate) de Fer, *Fr.;* Ferrum Sulfuricum, *P. G.;* Ferrosulfat, Schwefelsaures Eisenoxydul, *G.;* Solfato ferroso, *It.;* Sulfato ferroso, *Sp.*

The British Pharmacopœia (1885) contained the following process for this salt: "Take of Iron Wire *four ounces* [avoirdupois]; Sulphuric Acid *four fluidounces* [Imperial measure]; Distilled Water *one pint and a half* [Imp. meas.]. Pour the water on the Iron placed in a porcelain dish, and add the Sulphuric Acid, and, when the disengagement of gas has nearly ceased, boil for ten minutes. Filter now through paper, and, after the lapse of twenty-four hours, separate the crystals which have been deposited from the solution. Let these be dried on filtering paper placed on porous bricks, and preserved in a stoppered bottle." *Br.,* 1885.

The object of this process is to make a pure ferrous sulphate by direct combination. Sulphuric acid, in a concentrated state, acts but imperfectly on iron, but when diluted, a vigorous action takes place. The theoretical quantities for mutual reaction are 56 of iron to 98 of acid. This proportion is one part of iron to one and three-quarters of acid. The British Council uses an excess of acid, the weight of acid being 7.38 avoirdupois ounces, instead of 7. An excess of iron, however, is desirable, as it tends to secure the production of a perfect ferrous sulphate. A process for this salt was given in the U. S. P., 1870, which was based upon the method of Bonsdorff. This chemist found that, when a perfect ferrous sulphate was formed in solution by heating diluted sulphuric acid with an excess of iron, it might be crystallized free from sesquioxide, provided a little excess of sulphuric acid were added to the liquid before filtration, in order to prevent the formation of any sesquioxide during the process, at the same time avoiding, as much as possible, contact with the air. Hence the directions in the former U. S. Pharmacopœia formula to acidulate with sulphuric acid, to cause the funnel to touch the bottom of the receiving vessel, which avoids the dropping of the liquid through the air, and to cover the vessel containing the concentrated liquid when it is set aside to crystallize.

Commercial Ferrous Sulphate or *Copperas* is manufactured on a large scale for the purposes of the arts, from the native ferric sulphide or iron pyrites, by roasting, oxidation by exposure to air and moisture, and lixiviation. The constituents of the mineral become sulphuric acid and ferrous and ferric oxides, which, by their union, form the salt. Ferrous sulphate is also obtained in many chemical processes as a collateral or by-product, as in the manufacture of alum, in the precipitation of copper from solutions of copper sulphate by scraps of iron, in the manufacture of hydrogen, etc.

Commercial ferrous sulphate is far from being pure. Besides containing some ferric sulphate, it is generally contaminated with metallic and

earthy salts, such as those of copper, zinc, aluminum, and magnesium. Two principal kinds occur in the market, one in large grass-green crystals, the surface of which is studded with yellow spots; the other of a bluish-green color, and ordinarily mixed with the powder of the effloresced salt. Commercial sulphate should never be dispensed by the pharmacist until it has undergone purification by recrystallization from a slightly acid solution, and brought into compliance with the official requirements.

Properties.—Ferrous sulphate is in the form of "pale bluish-green, monoclinic prisms, without odor, and having a saline, styptic taste; efflorescent in dry air. On exposure to moist air, the crystals rapidly oxidize, and become coated with brownish-yellow, basic ferric sulphate. When it has thus deteriorated the salt must not be used for any official purpose. One Gm. of Ferrous Sulphate dissolves in 1.4 mils of water at 25° C. (77° F.); in 0.4 mil of boiling water; insoluble in alcohol. An aqueous solution of the salt (1 in 20) is acid to litmus. When slowly heated to 115° C. (239° F.) the crystals disintegrate, and the salt loses the greater part of its water of crystallization. An aqueous solution of the salt, even when highly diluted, gives with potassium ferricyanide T.S. a blue color or precipitate, and with barium chloride T.S. a white precipitate insoluble in hydrochloric acid. Dissolve 1 Gm. of the salt in about 50 mils of distilled water containing 1 mil of diluted sulphuric acid, heat the solution to boiling, oxidize it with nitric acid and then mix it with a slight excess of ammonia water and filter. The filtrate is colorless, and, after acidulating with hydrochloric acid, it does not respond to the Test for heavy metals (see Part III, Test No. 3). Agitate 1 Gm. of Ferrous Sulphate in small fragments during four or five minutes, with 10 mils of alcohol, and filter the mixture; the filtrate does not immediately redden moistened blue litmus paper (*free acid*).

"**Assay.**—Dissolve about 1 Gm. of Ferrous Sulphate, accurately weighed, in about 25 mils of diluted sulphuric acid and titrate with tenth-normal potassium permanganate V.S until a permanent pink color is produced. It shows not less than 54.36 per cent. nor more than 57.07 per cent. of $FeSO_4$.

"Each mil of tenth-normal potassium permanganate V.S. used corresponds to 0.015191 Gm. of $FeSO_4$. Each gramme of Ferrous Sulphate corresponds to not less than 35.78 mils nor more than 37.57 mils of tenth-normal potassium permanganate V.S." *U. S.*

"Oblique rhombic prisms of a greenish color, or a crystalline powder of a pale bluish-green color; taste astringent. Insoluble in *alcohol* (90 per cent.), soluble in less than 2 parts of *water* previously boiled and cooled, giving a clear solution (absence of oxysulphate). Yields the *reactions* characteristic of ferrous salts and of sulphates. 1 gramme dissolved in 20 millilitres of *diluted sulphuric acid* decolorises not less than 35 millilitres of *N/10 solution of potassium permanganate.* Yields no characteristic *reactions* for copper or zinc. *Arsenic limit* 2 parts per million." *Br.*

As prepared by Bonsdorff's method, ferrous sulphate is blue, verging upon green. When it becomes more green than blue, or entirely green, an indication is afforded that it contains some sesquioxide. By exposure to the air the crystals absorb oxygen, and become first green, and ultimately covered with a yellow efflorescence of subsulphate, insoluble in water. Sometimes the crystals are quite permanent when made by Bonsdorff's method, owing to the slight excess of acid which they contain. The aqueous solution is bluish green, but by standing it attracts oxygen, and becomes first green and then reddish depositing in the meantime a portion of sesquisulphate, having the composition:

$$Fe_2(SO_4)_3 + Fe_2O_3 + 8H_2O$$

At a red heat it loses its acid, and is converted into the anhydrous ferric oxide called *colcothar.* It is incompatible with the alkalies and their carbonates, soaps, lime water, calcium and barium chlorides, sodium borate and phosphate, silver nitrate, and lead acetate and subacetate. It is decomposed also by astringent vegetable infusions, the tannic and gallic acids of which form, if any sesquioxide be present, a black compound of the nature of ink. The extent to which this change lessens the activity of the salt is not well ascertained. Ferrous sulphate, as found in commerce, is often the impure commercial sulphate, which is not fit for medicinal use. The perfectly pure salt is precipitated white by potassium ferrocyanide, but that of ordinary purity gives a greenish precipitate, more or less deep, with this test, owing to the presence of some ferric salt. Copper may be detected by immersing in the solution a bright piece of iron, on which a cuprous film will be deposited. Both copper and zinc may be detected by oxidizing the iron by boiling the solution of the salt with nitric acid and then precipitating the iron by an excess of ammonia. If the filtered solution be blue, copper is present, and if it contain zinc, this will be separated in flakes of white oxide on expelling the excess of ammonia by ebullition.

It is often desirable to protect ferrous sulphate against the oxidation to which it is liable on exposure. Sugar acts as a preservative in the case of this salt, as in that of ferrous iodide. It may be added to the solution, or incorporated with the sulphate in substance. E. Latour has given a formula for crystallizing the salt with sugar. Geo. Welborn has found that a small lump of camphor, wrapped in tissue paper, and placed in the bottle with the sulphate, prevents its oxidation. (*P. J.*, May, 1868, p. 537.) Pavesi, of Mortara, effects the same object by incorporating it with an equal weight of gum arabic, by evaporating a joint solution of the two substances with a gentle heat. (*J. P. C.*, 4e sér., iii, 49.)

Uses.—Ferrous sulphate is an active local irritant and astringent. In overdoses it pro-

duces nausea, vomiting, griping, and purging, and other evidences of gastro-enteric irritation. Because of this action it is not to be recommended as an internal remedy. Externally, the solution has been used in chronic *ophthalmia, leucorrhea,* and *gleet,* made of various strengths, from one or two to eight or ten grains of the salt to the fluidounce of water. Velpeau has recommended in *erysipelas* the local use of a three per cent. solution applied by compresses kept constantly wet. An ointment made of one or two parts of the sulphate to sixty of lard was found by Devergie to be particularly efficacious in certain skin diseases, especially in *eczema.* In scaly affections it had no effect. (See *Ferri Sulphas Exsiccatus.*)

Ferrous sulphate, usually in the form of the impure salt or commercial copperas, is a disinfectant and deodorant as it unites with both hydrogen sulphide and ammonia. It is asserted that ferric sulphate unites with organic substances to form definite stable compounds, and that animal substances kept in a 3 per cent. solution of neutral ferric sulphate for some time and then removed, mummify without decomposition. (*N. R.,* Dec., 1883, 685.) Ferrous sulphate is incompatible with alkalies and also with even feeble oxidizing agents which quickly convert it into ferric sulphate or subsulphate.

Dose, two to five grains (0.13–0.32 Gm.).

FERRI SULPHAS EXSICCATUS. U. S., Br.

EXSICCATED FERROUS SULPHATE Ferr. Sulph. Exsic. [Dried Ferrous Sulphate]

(fĕr′rī sŭl′phăs ĕx-sĭc-cā′tŭs)

"Exsiccated Ferrous Sulphate contains the equivalent of not less than 80 per cent. of the anhydrous salt [$FeSO_4 = 151.91$]." *U. S.* "Exsiccated Ferrous Sulphate is Ferrous Sulphate deprived of part of its water of crystallization. It contains not less than 77 per cent. of pure anhydrous ferrous sulphate, $FeSO_4$." *Br.*

Ferri Sulphas Exsiccata, *Br.* 1885; Dried Sulphate of Iron Sulfate Ferreux desséché, *Fr.;* Ferrum Sulfuricum Siccum *P. G.;* Getrochnetes Ferrosulfat, Entwässertes Schwefel saures Eisenoxydul, *G.;* Sulfato ferroso desecado, *Sp.*

* "Ferrous Sulphate, in coarse powder, *one hundred grammes* [or 3 ounces av., 231 grains]. Allow the salt to effloresce at a temperature of about 40° C. (104° F.), in dry air, and then heat it in a porcelain dish, on a water-bath, constantly stirring, until the product weighs from *sixty-four* to *sixty-five grammes* [or 2 ounces av., 113 grains to 2 ounces av., 128 grains]. Lastly, reduce the residue to a fine powder, and transfer it at once to dry, well-stoppered bottles." *U. S.*

No process is given in the British Pharmacopœia, 1914. The 1898 process was as follows:

"Expose Ferrous Sulphate, $FeSO_4,7H_2O$, in a porcelain or iron dish to a temperature of 100° C. (212° F.), stirring occasionally until aqueous vapor ceases to be given off; reduce the residue, which should weigh about 60 per cent. of the original salt, to a fine powder."

Properties.—"Exsiccated Ferrous Sulphate is a grayish-white powder, slowly soluble in water. A solution of the salt (1 in 20) in distilled water which has been recently boiled and cooled is not more than slightly turbid, and conforms to the reactions and tests under *Ferri Sulphas,* except the test for free acid, when taken in proportionate amount.

"**Assay.**—Dissolve about 0.8 Gm. of Exsiccated Ferrous Sulphate, accurately weighed in a stoppered weighing-bottle, in about 25 mils of diluted sulphuric acid and titrate with tenth-normal potassium permanganate V.S. until a permanent pink color is produced. It shows not less than 80 per cent. of $FeSO_4$.

"Each mil of tenth-normal potassium permanganate V.S. used corresponds to 0.015191 Gm. of $FeSO_4$. Each gramme of Exsiccated Ferrous Sulphate corresponds to not less than 52.7 mils of tenth-normal potassium permanganate V.S." *U. S.*

"A nearly white powder, slowly but entirely soluble in *water.* 0.5 gramme dissolved in *water* and acidified with *sulphuric acid* decolorises not less than 25.3 millilitres of *N/10 solution of potassium permanganate. Arsenic limit* 5 parts per million." *Br.*

In this process about six molecules out of seven, of the water of crystallization of the salt, are driven off. The heat should not exceed 149° C. (300° F.), otherwise the salt itself would suffer decomposition. If the heat has been excessive, the color of the salt will be brownish instead of grayish-white. Dried ferrous sulphate is used for making pills, the crystallized sulphate not being adapted to that purpose. In prescribing the dried sulphate it is necessary to recollect that about three grains of it are equivalent to five grains of the crystallized salt.

Dose, one to three grains (0.065–0.2 Gm.).

Off. Prep.—Pilulæ Aloes et Ferri, *Br., N. F.;* Pilula Ferri, *Br.;* Pilulæ Ferri, Quininæ, Aloes et Nucis Vomicæ, *N. F.*

FERRI SULPHAS GRANULATUS. U. S.

GRANULATED FERROUS SULPHATE Ferr. Sulph. Gran. [Precipitated Ferrous Sulphate]

(fĕr′rī sŭl′phăs grăn-ū-lā′tŭs)

Granulated Sulphate of Iron; Ferri Sulphas Præcipitatus, *U. S. P.* 1880; Precipitated Sulphate of Iron; Sulfate Ferreux précipité, *Fr.;* Präcipitirtes Ferrosulfat, *G.*

* "Ferrous Sulphate, *one hundred grammes* [or 3 ounces av., 231 grains]; Distilled Water, *one hundred mils* [or 3 fluidounces, 183 minims]; Diluted Sulphuric Acid, *five mils* [or 81 minims]; Alcohol, *twenty-five mils* [or 406

minims]. Dissolve the Ferrous Sulphate in the Distilled Water previously heated to boiling, add the Diluted Sulphuric Acid, and filter the solution while hot. Evaporate the solution immediately in a tared porcelain dish, on a sand-bath, until it weighs *one hundred and fifty grammes* [or 5 ounces av., 127 grains], and then cool it quickly, with constant stirring. Transfer the product to a glass funnel stopped with a plug of purified cotton, and, when it has thoroughly drained, pour the Alcohol upon it. When this has also drained, spread the crystalline powder on bibulous paper, dry it quickly at room temperature, and transfer it at once to dry, well-stoppered bottles. Granulated Ferrous Sulphate is a very pale bluish-green, crystalline powder, which conforms in every respect to the reactions and tests for purity under *Ferri Sulphas.*" *U. S.*

The process of the U. S. P. (1890), retained by the U. S. P., differs radically in manipulation from that of 1880; instead of pouring the filtered solution of ferrous sulphate into alcohol and collecting the precipitate which falls, the solution is granulated by heat with constant stirring (not quite to dryness), and this salt is then washed with alcohol, which displaces impurities and facilitates the rapid drying of the granular powder.

The product is practically identical with the granulated sulphate of iron of the British Pharmacopœia (1885). The British Pharmacopœia (1898) omitted the granulated salt entirely. The process of the U. S. Pharmacopœia of 1880 had the advantage of being more manageable and convenient, ferrous sulphate being used directly instead of being made by the action of sulphuric acid on the metal. The directions given in the first part of the former British process are precisely the same as those laid down by the British Council for making ferrous sulphate; but the hot solution of the iron in the sulphuric acid, instead of being allowed to filter into an empty vessel, is made to drop into a portion of alcohol, the mixture being stirred while it cools. The acid directed is in excess, and the filtrate is consequently an acid solution of ferrous sulphate mixed with alcohol. The stirring as the mixture cools, finely granulates the salt, which separates perfectly pure, the alcohol holding in solution any ferric sulphate which may have been formed, and the excess of acid dissolving any free sesquioxide. This process, in its main features, is that of Berthemot. (See 8th ed., U. S. D.)

Properties.—Barckhauser, Salzer, and others have stated that ferrous sulphate precipitated by alcohol did not always contain seven molecules of water, and it could not be relied upon for making volumetric solutions because of this lack of uniformity in composition. Caro (*Ann. Ch. Ph.,* clxv, 29) and Schlickum (*Ph. Ztg.,* No. 49), on the other hand, maintain that precipitated ferrous sulphate is constant in composition, and Schlickum proved that if the precipitation took place in the cold it always contained seven molecules of water, but *boiling* with strong alcohol diminished the proportion of water of crystallization. This salt is less liable to oxidation on exposure than is the sulphate in its ordinary form, and experience has shown that it is admirably adapted for dispensing.

Dose, two to five grains (0.13–0.32 Gm.).

Off. Prep.—Pilulæ Ferri Carbonatis, *U. S.*

FERRUM. U. S., Br.

IRON Ferr.

(fĕr'rŭm)

"Metallic iron [Fe = 55.84] in the form of fine, bright wire." *U. S.* "Iron is annealed iron wire, having a diameter of about 0.1 millimetre (about No. 35 wire gauge), or wrought-iron nails, free from oxide. *Arsenic limit* 200 parts per million." *Br.*

Fer, Mars, Fer métallique, *Fr. Cod.;* Fil de Fer, *Fr.;* Eisen, Eisendraht, *G.;* Ferro, Limatura di ferro, *It.;* Hierro, *Sp.*

In the U. S. Pharmacopœia, this metal is employed in different preparations in the form of wire; it was official in 1850 as *Ferri Ramenta, Iron Filings.* See *U. S. Dispensatory,* 19th edition, p. 514.

Iron is the most abundant and useful of the metals, and so interwoven with the wants of mankind that the extent of its consumption by a nation may be taken as an index of progress in civilization. It is universally diffused in nature, not only in the mineral but also in the vegetable and animal kingdoms. There are very few minerals in which traces of it are not to be found, and it is an essential constituent in many parts of animals, but particularly in the blood. It is one of the few metals which are not deleterious to the animal economy. Iron occurs: (1) native (almost exclusively, however, of meteoric origin); (2) as a sulphide, in the minerals *pyrites, pyrrotine,* or *magnetic pyrites,* and *arsenopyrite* or *mispickel* (a sulph-arsenide of iron); (3) oxidized, embracing the magnetic, specular, red, brown, and argillaceous iron oxides, also *chromite* (mixed iron, chromium, and magnesium oxides) and *franklinite* (mixed iron, manganese, and zinc oxides); (4) in saline combination, forming ferrous carbonate, sulphate, phosphate and arsenate. Those minerals of iron which admit of being worked to advantage are called *iron ores.* These include the different native oxides and the carbonate (spathic iron). The best iron is obtained from the ferroso-ferric oxide usually called magnetic iron ore, and the anhydrous sesquioxide, known as specular iron ore. These occur abundantly in Sweden, and furnish the superior iron of that country. The upper peninsula of Michigan and the borders of Lake Champlain in New York yield similar ores. As a rule, those ores yield the best iron which occurs in primitive formations.

Extraction.—The mode of extracting iron from its ores varies somewhat with the nature

of the ore; but the general principles of the operation are the same for all. The ore, previously broken into small pieces and roasted, is exposed to the action of an intense heat, urged by an air blast, in contact with carbonaceous matter, such as charcoal, coke, or anthracite, and in connection with some flux capable of fusing with the impurities of the ore. The flux varies with the nature of the ore, and is generally limestone. Fluorspar is occasionally used, but is not often found in sufficiently large deposits to be available. The flux, whatever it may be, enters into fusion with the impurities, and forms what is called the slag, which is a fusible lime silicate chiefly, while the carbon monoxide formed from the carbonaceous matter, acting on the ferric oxide, reduces it to the metallic state. The reduced metal, from its density, occupies the lower part of the furnace, and is protected from the action of the air by the melted slag which floats on its surface. When the reduction is completed, the slag is allowed to run out by a hole in the side of the furnace, and the melted metal by an aperture at the bottom, the latter being received into a series of sand moulds, where it solidifies in masses, known in commerce by the name of *pig* or *cast iron*. In this state the metal is brittle and far from being pure, as it contains from 3 to 6 per cent. of carbon, with silicon, phosphorus, sulphur, and manganese. It is purified, and brought to the state of *malleable iron*, by being fused and subjected, while stirred, to the action of a current of air on its surface. By these means the carbon is nearly burnt out, and the other impurities are oxidized and made to rise to the surface as a slag. Instead of this process, called "refining," usage in this country and in England substitutes what is called "pig boiling"—that is, the pig iron is at once submitted to the operation of puddling without previous refining. The "puddling" process consists in heating the charge of pig iron on the hearth of a reverberatory furnace in contact with ferric oxide and in a reducing flame. The silicon is first burnt out, and then the carbon gradually disappears; the phosphorus goes into the "tap cinder" as phosphide and phosphate; the sulphur in part disappears as sulphur dioxide and in part remains in the cinder as ferrous sulphide. As the metal approaches to purity, it becomes tough and less liquid, and its particles agglutinate so as to form semi-fused lumps, though the temperature of the furnace continues the same. These lumps are then taken out of the furnace, and their particles, by means of ponderous hammers moved by steam or water power, or by great pressure, are forced together so as to form one tenacious mass. The metal is finally rolled out into bars of a convenient size, when it constitutes *wrought iron* of commerce.

The third form of commercial iron, known as "steel," is made either by the *cementation* process, the *Bessemer* process, the *open hearth* process, or by *electrical* processes. In the first case, wrought iron is packed with charcoal and heated until combination takes place, and the resulting steel is cast into ingots. In the second case, cast iron is melted in large vessels called converters, when a blast of air is blown through the mass, burning out the requisite amount of carbon, and then, after addition of a small amount of *spiegeleisen*, or manganiferous cast iron, the finished product is run into moulds; while in the third or open hearth process, a mixture of pig iron and ore is heated with a reverberatory flame, as in the puddling process, or bars and blooms of wrought iron are heated with the pig iron, and steel is made by the combination of the two. Steel contains from ½ to 1 per cent. of carbon.

Iron mines occur in most countries, but more particularly in northern ones. In Spain the principal mines furnish spathic iron and the red oxide. The chief iron ores of France are the spathic iron, and the specular, brown, and argillaceous oxides; of Germany, the spathic iron and brown oxide. The island of Elba is celebrated for its rich and abundant specular iron ore. In the United States iron is abundant. The principal ores that are worked are the magnetic, red, and brown oxides. The magnetic oxide is found in large beds in Essex County, N. Y., on the borders of Lake Champlain, and in the Lake Superior district; the red oxide in New York, New Jersey, Pennsylvania, Alabama, and especially in a very pure state in Missouri, at Iron Mountain and Pilot Knob; the brown oxide in Eastern Pennsylvania.

Properties.—Iron is a hard, malleable, ductile, and tenacious metal, of a grayish-white color and fibrous texture, a characteristic taste, and a sensible odor when rubbed. In tenacity it yields only to nickel and cobalt. (Deville.) Its sp. gr. is about 7.7, and its fusing point very high, about 1510° C. (2750° F.). It possesses magnetic properties and is very malleable. It is combustible, and, when heated to whiteness, burns in atmospheric air, and with brilliant scintillations in oxygen gas. At a red heat, its surface is converted into black oxide, and at common temperatures, by the combined agency of air and moisture, it becomes covered with a yellowish-brown matter, called *rust*, which is the hydrated sesquioxide. It combines with all the non-metallic elements, except hydrogen and nitrogen, and with most of the metals. It forms three compounds with oxygen, a ferrous oxide and a ferric oxide, which by their union form the native magnetic oxide, hence often termed ferroso-ferric oxide, and a trioxide, which forms an acid called ferric acid. The *monoxide*, or ferrous oxide, is of a dark blue color, attracted by the magnet, and spontaneously combustible in the air, being converted into sesquioxide or ferric oxide. It is the base of ferrous sulphate, and the green salts of iron generally. It is very prone to absorb oxygen, and hence the salts which contain it are soon partially converted, when in solution, into salts of the ferric oxide.

Its formula is FeO, consisting of one atom of iron, Fe, and one of oxygen, O. The *sesquioxide*, or ferric oxide, is readily obtained by dissolving iron in nitrohydrochloric acid, precipitating by ammonia, and igniting the precipitate. It is of a red color, not attracted by the magnet, and forms salts which for the most part have a reddish color. Its formula is Fe_2O_3, consisting of two atoms of iron, Fe, and three atoms of oxygen, O. An allotropic variety of the sesquioxide, soluble in water, and not responding to the ordinary tests of iron, has been discovered by Péan de Saint-Gilles. The *native black oxide*, the magnetic oxide of mineralogists, consists of one molecule of FeO and one molecule of Fe_2O_3.

Under the name of *Ferri Oxidum Magneticum*, the British Pharmacopœia formerly had a preparation consisting of this oxide with three molecules of water. *Ferric acid*, discovered by Frémy, may be obtained, in union with potassium hydroxide, by passing chlorine through a very concentrated solution of the alkali, holding the hydrated ferric oxide in suspension, or by fusing iron filings with potassium nitrate. The acid anhydride consists of one atom of iron and three of oxygen, FeO_3. Iron forms a number of important salts.

Iron is readily detected, even in minute quantities, by bringing it to the state of ferric salt in solution, and adding potassium ferrocyanide or tincture of galls, the former of which will strike a deep blue, the latter a black color. Bringing it to the state of a ferric salt is readily effected by boiling the solution containing it with a little nitric acid. F. B. Power prefers the *iodometric method* for estimating the quantity of iron in scaled salts. It is based on the liberation of iodine by ferric iron, and the subsequent estimation of the liberated iodine by a tenth-normal volumetric solution of sodium thiosulphate. (*Ph. Rund.*, 1891, 205.)

Uses.—The only condition in which the value of iron, as an internal remedy, has been proven beyond cavil is in certain types of *anemia*. The conditions of the blood which are characterized by a reduction in the percentage of hemoglobin may be divided into three groups, those in which the number of corpuscles is reduced to a greater extent than the percentage of hemoglobin—each individual corpuscle, therefore, being richer than normal in coloring matter—second, those in which the reduction in the number of corpuscles and the quantity of hemoglobin is approximately equal, and thirdly, those in which the number of corpuscles is not reduced as much as the percentage of hemoglobin—each corpuscle being poor in coloring matter. The first condition is seen typically in cases of pernicious anemia; the second in the so-called accidental anemias, those which are due to hemorrhage, wasting diseases, etc.; and the third is seen in chlorosis. The value of iron in any individual case of impoverishment of the blood is in proportion as the condition approaches the chlorotic type. In true *pernicious anemia*, iron is probably of no value at all, in the accidental or secondary anemia, it is often of considerable service, and in true *chlorosis* it almost reaches the height of a specific.

Some years ago, certain chemists, failing to find any increase in the amount of iron in the urine after the administration of the inorganic salts of iron by the mouth, were led to believe that these forms of iron were not absorbable from the intestinal tract, and the theory had at one time a considerable number of adherents. It would carry us beyond the proper bounds of an article for the Dispensatory to go into all the evidence for and against the absorbability of iron, and the reader interested in the details is referred to H. C. Wood, Jr.'s *Pharmacology*. The subject may be summed up for the present purposes with the statement that it has been as firmly established as any fact in pharmacology, that the inorganic salts of iron are absorbed through the intestinal walls, and exercise a direct influence upon the blood making organs. That the amount of iron in the urine is not increased is owing to the fact that the great bulk of the metal is eliminated through the intestinal glands; this is true whether the drug be given by the mouth or hypodermically. Because of the former vogue for the theory of the non-absorption of iron, various chemists were led to place upon the market preparations which are spoken of as "organic iron" or "masked iron," supposed to be in a more assimilable form than the pharmacopœial salts. There is no convincing evidence that any of these preparations has any advantage over the inorganic salts, except, perhaps, a little less liability to disturb digestion. Indeed, the experiments of Abderhalden (*Z. B.*, 1900, xxxix) indicate that the iron in organic combination is of less value for the treatment of anemia than when in the inorganic form. Because iron is an essential constituent of the hemoglobin, it was formerly almost universally believed, and still is to a considerable extent, that it acted in anemia as a food-stuff; but this belief has for its base mere assumption, and the infinitesimal amount of iron which is consumed in the human body, as well as the fact that patients with chlorosis are not cured by feeding upon the foods rich in iron, throws great doubt upon this ancient legend, and the experiments of Abderhalden, quoted above, furnish almost conclusive proof of its error. It is far more probable that the action of iron is due to a stimulating effect upon the blood making organs analogous to the stimulant action of caffeine upon the kidneys, or strychnine upon the spinal cord.

The question of the selection of a preparation of iron for an individual case is often one of great importance. If it be simply desired to combat anemia, a preparation should be selected which is free as may be from astringency. Most of the liquid preparations of iron are more or less injurious to the teeth, so that

commonly it is preferable to give a solid salt in pill or capsule rather than one of the liquid forms, unless the latter be especially indicated.

It would be much better if the U. S. P. recognized only a fraction of the present official preparations. All that can be accomplished with any preparation in simple anemia can be done with reduced iron or pill of the carbonate for exhibition in solid form and the ammonio-citrate or soluble phosphate for liquids. No compounds in which iron is combined with an alkaloid should be recognized by the Pharmacopœia or used by the practitioner. Of course, such combinations are to a greater or less extent effective, but the proportionate amount of the alkaloid and the iron required in individual cases varies indefinitely, and the habitual use of a fixed proportion, such as is demanded by the pharmacopœial combinations, strongly inclines the practitioner of medicine to careless and routine practice. The official alkaloidal-ferruginous preparations have no advantage whatever over extemporaneous prescriptions combining iron and the alkaloid.

Certain salts of iron are extremely astringent and more or less irritant. The most important of these are the sulphates and the chlorides. These salts should never be employed as chalybeates, except in those cases in which, for some reason, astringency is desired. In some cases some laxative should be combined with iron to overcome its constipating influence.

Iron has been employed hypodermically to some extent. It has been asserted by the chemists working under Kobert, of Dorpat, that when a solution of iron and sodium citrate is injected subcutaneously in man, 40 per cent. of the iron escapes in the urine unaltered, the elimination of the iron usually being accompanied by pronounced renal irritation. The hypodermic use of some of the organic compounds of iron has been strongly recommended by investigators. The latest researches seem, however, to show that the iron citrate is as good a preparation for the hypodermic administration of iron as any other, the iron appearing in the urine half an hour after its injection and being present for twenty-four hours. According to Gloevecke, 1 mil of a 10 per cent. solution, thrown into the muscles of the back, causes an enduring sharp pain, but Lepine asserts that 2.5 mils of a 4 per cent. solution produces little or no disturbance. It is stated that after the hypodermic injection of large doses the irritation of the alimentary canal is more severe than when the drug is given by the mouth—a statement which finds confirmation in the experiments of Gottlieb, who found that when he injected iron subcutaneously into a dog he was able to obtain nearly 97 per cent. of it from the fæces. The effort at intestinal elimination is evidently accompanied by irritation if the amount of iron to be eliminated is large.

FERRUM REDUCTUM. U. S. (Br.)

REDUCED IRON Ferr. Reduct. [Iron by Hydrogen, Quevenne's Iron]

(fĕr'rŭm rę-dŭc'tŭm)

"Iron reduced to the metallic state by the action of hydrogen upon ferric oxide. It contains not less than 90 per cent. of metallic iron [Fe = 55.84]. Preserve it in well-closed containers." *U. S.* "Reduced Iron may be obtained by reducing ferric hydroxide, heated to dull redness, by means of a stream of dry hydrogen. It contains not less than 80 per cent. of metallic iron, with a variable amount of iron oxide." *Br.*

A process for this form of iron is no longer given in the United States Pharmacopœia. (See *U. S. Dispensatory,* 19th edition, page 518.)

This preparation was introduced into the United States and Dublin Pharmacopœias of 1850, and is retained in the present edition of our own, although the process for it has been abandoned. It consists of metallic iron in fine powder, obtained by reducing the ferric oxide by hydrogen at a dull red heat. The subcarbonate of the U. S. Pharm., 1870, which is essentially the ferric oxide, is deprived of water by calcination, and then subjected to the reducing influence of a stream of hydrogen, purified from hydrogen sulphide and acid compounds by passing successively through a solution of lead subacetate and milk of lime. The hydrogen unites with the oxygen of the ferric oxide to form water, and leaves the iron in the metallic state. The ferric oxide should be perfectly free from sodium sulphate, which it is likely to contain when imperfectly washed. If this salt be present, it will be reduced by the hydrogen to the state of sodium sulphide, which will contaminate and spoil the metallic iron formed, and cause the preparation, when taken internally to give rise to unpleasant eructations. The heat should be carefully regulated, for if it fall below dull redness, part of the oxide will escape reduction, and if it exceed that point considerably, the particles of reduced iron will agglutinate, and the preparation will be heavy and not readily pulverizable. The 1885 British process is not so well fitted for practical purposes as is that of the U. S. Pharm., 1870. In the 1885 revision of the British Pharmacopœia, instead of directing a certain quantity of hydrated ferric oxide, a process is given in the formula for making the ferric oxyhydrate by precipitating a solution of ferric chloride. The direction to dry the hydrogen is unnecessary. On the subject of powder of iron, manufac-

turing chemists will find it useful to consult the paper of Soubeiran and Dublanc, in which full directions are given for purifying the hydrogen, constructing the furnace, regulating the heat, and avoiding explosions. (*A. J. P.*, xviii, 303.) For improvements by Procter, see *A. J. P.*, xix, 11. The necessity for purification of the hydrogen by passing it successively through concentrated potassium permanganate solution, lead acetate solution, and sulphuric acid has been proved by T. Appel. (*Oest. Zeit. f. Pharm.*, 1892, 395.)

Various processes have been proposed for obtaining powder of iron. Arthur Morgan, of Dublin, recommended the use of dried potassium ferrocyanide, thoroughly mixed with anhydrous ferric oxide, and calcined with pure potassium carbonate at a low red heat. The product contains all the iron in a reduced state, mixed with soluble matters, which are carefully washed away. (See *A. J. P.*, 1854, p. 450.) A similar process to the above has been proposed by a German chemist, named Zängerle, iron oxalate being substituted for the ferric oxide. (See *P. J.*, 1857, p. 565.) Wöhler recommended the use of the same oxalate, not in connection with potassium ferrocyanide, but as a suitable compound of iron for reduction by hydrogen. W. Müller found that ferric oxide obtained by heating the metal in the air is reduced when moist at 293° C. (559.4° F.); when quite dry, at 305° to 339° C. (581°–642.2° F.); the oxalate moist, at 278° C. (532.4° F.). Another eligible compound for reduction is the crystalline powder of ferric oxide, prepared by fusing, in a clay crucible, pure dried ferrous sulphate with three times its weight of sodium chloride, and then washing the melted mass when cold, until everything soluble is removed. (Wöhler.) Crolas prepares a pure ferric oxide by adding barium chloride to the solution of ferric chloride to precipitate the contaminating sulphate, getting rid of the barium chloride by crystallization and precipitating by solution of ammonia. The ammonium chloride is driven off by heat. (*J. P. C.*, 4e sér., xx, 30.) The process of Eugène Fegueux consists in reducing the ferric oxide by carbonic oxide, formed by passing a stream of carbon dioxide over a red hot charcoal in the reduction tube, before it reaches the ferric oxide. The carbon dioxide, thus reduced to carbonic oxide, is formed again by the deoxidizing of the ferruginous oxide.

Under the name of "*alcoholized iron*," a powdered iron was at one time sold in this country, said to be prepared, in the eastern parts of Germany, by attrition of iron filings with honey, by some cheap method, as by attachment to a saw mill or steam machinery. It had the appearance of powdered plumbago, but under the magnifying glass was seen to contain particles with metallic luster and rounded as if by friction. It was soluble in diluted sulphuric acid, with the escape of hydrogen, free, or nearly so, from sulphur, but a small quantity of black powder remained undissolved. (*A. J. P.*, 1867, p. 11.) The relation of the epithet "alcoholized" to this powder is an example of an unusual use of the word alcohol, which in the Arabic means "very finely divided." The word alcoholize, therefore, simply means to reduce to an impalpable powder and has been so used since its first use by Phillips in 1706. It is not much inferior to reduced iron, and is better than some preparations sold by that name.

Properties.—Reduced iron is a light, tasteless powder, soft to the touch, of an iron-gray color, and without metallic luster. If black, the preparation is to be rejected as not being fully deoxidized. When thrown into a diluted acid, it causes a lively effervescence of hydrogen without odor. A small portion of it, struck on an anvil with a smooth hammer, forms a scale having a brilliant metallic luster. It takes fire upon the application of a flame. On account of its great liability to oxidation, it should be kept in a dry bottle, well stoppered. A black powder, having a composition corresponding with that of the magnetic oxide of iron, was formerly sold under the name of Quevenne's iron. This synonym is now applied to the official product. The spurious powder may be known by its having a black instead of an iron-gray color, and by its effervescing but slightly with acids. In the process for making reduced iron, part of the oxide almost always escapes full deoxidation, and comes out of the tube having a black color. This part should be rejected, instead of being sold as reduced iron, as appears to have been done by some manufacturing chemists. If the preparation has been very badly made, its solution in diluted sulphuric acid will produce an intensely red color with potassium sulphocyanate. It is officially described as "a very fine, grayish-black, lusterless powder, without odor or taste; permanent in dry air. Reduced Iron is insoluble in water or alcohol. When ignited in contact with air, it glows and is converted into black ferroso-ferric oxide. Shake 1 Gm. of Reduced Iron with 5 mils of distilled water and filter; the liquid does not change the color of litmus. One Gm. of Reduced Iron, when treated with 20 mils of diluted sulphuric acid in a flask, causes the evolution of nearly odorless hydrogen gas, which does not affect paper moistened with lead acetate T.S. within two minutes (*sulphide*), and, on applying a gentle heat, the Iron dissolves in the acid without leaving more than 1 per cent. of residue. Add 20 mils of diluted sulphuric acid to 0.5 Gm. of Reduced Iron contained in a small, covered beaker, and, after the reaction has somewhat subsided, warm the liquid on a water bath until the reaction ceases. Collect any minute, undissolved residue upon a very small filter, rinse the beaker with distilled water, add the rinsings to the filter, and then wash the residue with distilled water until free from acid reaction. Transfer the residue to the beaker by rinsing it back, and, after adding about 0.25 Gm. of potassium chlorate and 5 mils of hydrochloric acid, slowly evaporate the

solution to dryness on a water bath. Dissolve the residue in sufficient distilled water to measure 50 mils, and add 5 mils of this solution to 5 mils of a saturated solution of sulphurous acid and heat the liquid on a water bath for fifteen minutes, or until all traces of sulphurous acid have been removed. The resulting solution meets the requirements of the Test for arsenic (see Part III, Test No. 1).

"**Assay.**—Introduce into a 100 mil flask about 1 Gm. of Reduced Iron, previously well triturated and accurately weighed, and add 10 Gm. of fine powdered mercuric chloride and 50 mils of boiling distilled water. Boil the mixture for five minutes, shaking it frequently, then fill the flask to the 100 mil mark with distilled water, recently boiled and cooled, and cool it to room temperature. Again fill the flask to the mark with distilled water, stopper, agitate the contents well, and allow it to stand for a few minutes. Now filter the contents of the flask and immediately titrate 20 mils of the filtrate to which has been added 20 mils of diluted sulphuric acid, with tenth-normal potassium permanganate V.S. until a permanent pink color is produced. It shows not less than 90 per cent. of Fe when calculated from the original weight of Reduced Iron taken.

"Each mil of tenth-normal potassium permanganate V.S. used corresponds to 0.005584 Gm. of Fe. Each gramme of Reduced Iron corresponds to not less than 161.2 mils of tenth-normal potassium permanganate V.S." *U. S.*

"A fine greyish-black powder, strongly attracted by the magnet, and producing metallic streaks when rubbed with firm pressure in a mortar. Dissolves in *hydrochloric acid* with evolution of hydrogen, and without any odor of hydrogen sulphide, the solution giving a light-blue precipitate with *solution of potassium ferrocyanide.* When 0.25 gramme, in very fine powder, is added to a hot solution of 1.25 grammes of *copper sulphate* in 20 millilitres of *water,* the mixture kept hot and occasionally well shaken during ten minutes, and then rapidly filtered with the minimum of exposure to air, the filtrate decolorises not less than 35.8 millilitres of *N/10 solution of potassium permanganate.* Not more than 1 per cent. is insoluble in *hydrochloric acid. Arsenic limit* 200 parts per million." *Br.*

O. E. Winter (*J. A. P. A.*, 1913, p. 296) presents a critical review of the methods and requirements in all existing pharmacopœias and compares the efficiency of the various official methods for the determination of the iron. He favors the mercuric chloride method adopted in the U. S. P. IX, when accompanied by a limiting test for sulphides, which when present in large amounts, interferes with the accuracy of the method.

Uses.—Powder of iron, reduced from the oxide by hydrogen, was first prepared for medicinal purposes by Quevenne and Miquelard, of Paris. It is one of the best of the chalybeate tonics, nearly free from astringency. Observations to determine its therapeutic value, compared with that of the other ferruginous preparations, were made by Costes, for nearly four years, at the Saint-André hospital of Bordeaux, with the results highly favorable to it. It is sometimes prepared with chocolate in the form of lozenges.

Dose, one to three grains (0.065–0.20 Gm.) several times a day, given in powder or in pill.

FLUIDEXTRACTA. U. S. (Br.)

FLUIDEXTRACTS

(flū-id-ĕx-trăc'tă)

Extracta Liquida, *Br.;* Fluid Extracts; Extraits liquides, *Fr.;* Extracta fluida, *P. G.;* Fluidextrakte, Flüssige Extrakt, *G.*

"Fluidextracts are concentrated liquid preparations of vegetable drugs, containing alcohol either as a solvent or as a preservative, and bearing a uniform relation to the drug used so that *one mil* of the fluidextract closely represents the activity of *one gramme* of the air-dried and powdered drug of standard quality." *U. S.*

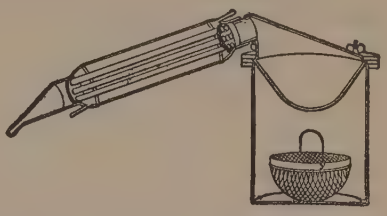
The Latin title Extractum —— Fluidum formerly used for Fluid Extracts was dropped by the U. S. P. VIII because of the confusion which resulted from the necessary bringing together of the extracts and fluid extracts due to a strict alphabetical arrangement; the name "fluidextractum" is now used for "fluidextract" and the latter made one word; this, of course, brings the fluidextract under the letter F instead of the letter E under which extracts and fluidextracts were formerly both classed.

Fluidextracts were first introduced into the U. S. P. of 1850 as a distinct class of preparations, the fluidextract of sarsaparilla being the only one previously directed, either in our own official code or by the British Colleges. Now we have one hundred and fifty-seven that are official in the U. S. P. IX, British Pharm., 1914, and National Formulary IV, besides large quantities of non-official fluidextracts annually produced. They are now perhaps the most important class of liquid preparations in use. Their distinctive character is the concentration of the active ingredients of medicinal substances into a small bulk, in the liquid form, a cubic centimeter, mil, or fluidgramme of any one of them now representing a gramme of the crude drug. In addition to convenience of administration, the advantage of these preparations is that, evaporation not being carried so far as in ordinary extracts, the active principles are less liable to be injured by heat. Formerly their main difficulty was the liability of substances in the liquid state to undergo spontaneous decomposition. In the U. S. P. of 1850 this was counteracted by means of sugar and of alcohol, but in 1865 (*A. J. P.*, 1865, p. 50) Taylor proposed the use of glycerin,

which was adopted in the U. S. P., 1870, revision. Glycerin, while it exerts a powerful preservative influence, possesses the valuable property of dissolving matters deposited by some of the fluidextracts when made with sugar, as in the old official recipes. Consequently these fluidextracts were much clearer and better preparations than were the old ones. Subsequent experience with these fluidextracts showed that the use of glycerin should be circumscribed, and that it had been employed too freely in the U. S. P., 1870, formulas. The solvent powers of glycerin are so great that the fluidextracts were frequently loaded with many inert principles, which it dissolved, giving them a dense, rich appearance, without increasing their activity. As the primary object of fluidextracts is concentration, suitable menstrua should in each case be selected with the single object of dissolving and retaining permanently the active constituents of the drug.

The present fluidextracts are of the same strength as those formerly official, and the formulas are based upon the theory that from a given weight of drug an amount of fluidextract shall be made equal in measure to the bulk of the same weight of distilled water; in other words, upon the relation of gramme to millilitre. Although the metric system is admirable in practice, some may prefer to use ordinary weights and measures; in such cases, to make 20 *fluidounces* of a fluidextract 19 *troyounces* of drug will be required, while if avoirdupois weight is preferred, the most convenient relation to recollect will be that 50 *avoirdupois ounces* are required to make 48 *fluidounces,* or *three pints,* of a fluidextract. It has been repeatedly proposed to make 50 *per cent. tinctures* or half-strength fluidextracts, the main object being to secure more representative preparations when made on the small scale. Experiments by Sayre, Gregory, Patch, and others prove that half-strength fluidextracts possess no advantages over those of official strength. (*D. C.*, 1897, 119, 147.) The precipitation experienced heretofore, when the evaporated weak percolate was added to the reserved portion, is considerably diminished by causing the former to be evaporated to a soft extract. This precipitation, formerly noticed more particularly in alcoholic fluidextracts, was due to the greater volatility of the alcohol in the weak percolates, which, when evaporated, left the residue to a great extent aqueous; when this was added to the strongly alcoholic reserved portion, a precipitation of resinous and frequently active matter took place, which necessitated the storing of the fluidextract until precipitation ceased, and subsequent filtration. This is not altogether avoided by evaporating to a soft extract, but the loss of activity through precipitation is thus greatly diminished. Fluidextracts invariably deposit insoluble matter upon standing, and those made in warm weather, owing to the greater solvent powers of the menstrua (due to the elevated temperature) are found to deposit more freely than the same kind of fluidextracts if made in the winter time with menstrua correspondingly reduced in temperature.

A useful distillatory apparatus has been contrived by Joseph P. Remington for recovering alcohol from weak percolates, and for general pharmaceutical uses. The still shown in the cut is the new form. It is made of tinned copper, the still body holding about three gallons; the condenser has seven straight tubes surrounded



with the cold water introduced by a rubber tube from a hydrant or bucket of water placed higher than the still, and carried off as it becomes warmed by the tube shown at the upper part of the condenser. By a siphon arrangement not shown in the cut, the still can be fed from a reservoir while distillation is in progress, thus using a three gallon still where otherwise a much larger one would have been necessary. The joints are carefully ground, and troublesome lutes and water joints are entirely superseded. The condenser, having straight tubes instead of a spiral one, is easily cleaned, and is powerful enough to condense a gallon of alcohol in thirty minutes. The still may be set into a kettle partly filled with water and thus used as a water bath, or a shallow tinned copper dish with flat rim, which accompanies the still, may be placed between the two brass ring bands and clamped securely. (*A. J. P.*, May, 1879.) Remington's *Practice of Pharmacy,* Fourth ed., page 158.

For valuable papers on percolation and fluidextracts, by William Procter, E. R. Squibb, Alonzo Robbins, and others, see *Proc. A. Ph. A.*, 1859, p. 265; 1863, p. 222; *A. J. P.*, 1878, pp. 209, 329; 1873, pp. 85, 189.

Several methods have been suggested for preparing fluidextracts more economically. The use of acetic acid as a menstruum to replace alcohol or diluted alcohol has the merit of economy. (See *Extracta,* also *A. J. P.*, 1899, 1–14; *Proc. Pennsylvania Pharm. Assoc.*, 1898, 116; *A. J. P.*, 1898, 543; *A. J. P.*, 1899, 67; *Ph. Era,* 1898, 796; *Proc. Minnesota Pharm. Assoc.*, 1902, 103; *West. Drug.*, 1903, 652.)

The most important modification is the plan of repercolation, as proposed by E. R. Squibb, for this class of preparations as well as the dry extracts.

Repercolation.—In consequence of the existing high price of alcohol, it is important to adopt some plan by which, while the ends aimed at are attained, the consumption of the men-

struum used in percolation may be diminished. This object has been accomplished, to a considerable extent, by E. R. Squibb, of Brooklyn, N. Y., by a modification of the process of percolation to which he has given the name at the head of the present paragraph. As defined by the author, repercolation consists in the successive application of the same percolating menstruum to fresh portions of the substances to be percolated. The result is that the same menstruum, acting repeatedly on unexhausted portions of the substance, becomes concentrated to the greatest possible extent, so that much of the menstruum is saved, while subsequent evaporation is avoided, which is itself an object of great importance in the preparation of extracts. It is obvious that repercolation is not applicable to the preparation of infusions, decoctions, tinctures, etc., in which the object in general is less a high degree of concentration than precision in the strength of the preparation, and consequently in the dose. It is to the extracts and fluidextracts that the process is peculiarly adapted, and there now remains no doubt whatever of the great value of the improvement. One of its disadvantages is that the substance treated is less completely exhausted than when the proceeding is inverted, and fresh portions of menstruum are made to act on the same material until the latter is deprived of all its soluble matter. But the loss in this way is trifling, compared with the gain when a menstruum as high-priced as alcohol is employed.

Another practical disadvantage is the inconvenience of keeping the weak percolates, as these have to be labelled, numbered, and stored away for use until the same operation is repeated. In deciding when to adopt it, the operator will, of course, be influenced by the relative value of the drug and the menstruum. In order to secure the most favorable results in repercolation, certain methods of proceeding are advisable in various steps of the process, differing with the character of the substance to be acted on; and these can be determined only by a careful study, confirmed by repeated experiment. Squibb used repercolation exclusively on the large scale in the manufacture of extracts and fluidextracts, and applied it especially to the preparation of fluidextracts of cinchona; and since his first paper, which was reproduced in the 14th revision of the U. S. Dispensatory, p. 1164, he introduced several improvements, which are intended to make the process useful to the apothecary in his every-day work. See Type Process C, page 484.

The plan of N. Spencer Thomas consists in exposing the substance to be acted on to successive expressions, by means of a press, with the menstruum divided into different portions, so that fresh portions of liquid are brought to act on the same solid body in different stages of exhaustion, and then mixing the expressed liquids. The due proportion between the weight of the medicine and the bulk of the ultimate fluidextract is secured by regulating the measure of the last added portion of menstruum, which, in the process as described by Thomas, is the third. Whatever may be the advantages of this method—and it is not without its recommendations—it is liable to the objection of loss of alcohol through exposure during expression. Another method of limiting the quantity of alcohol used has been proposed by S. P. Duffield, of Detroit. It consists in macerating, for from six to ten days, the medicine to be acted on, previously deprived, by means of a vacuum apparatus, of all the air, and of all readily volatilizable matter contained in its pores, with a certain volume of the menstruum, which is forced through a tube into the vacuum pan by atmospheric pressure, and thus brought into the most intimate contact with all parts of the powder. The process is completed by submitting the mass thus impregnated to hydraulic pressure, and, after allowing the liquid to settle in glass carboys, drawing off the clear liquid into bottles. It is obviously inapplicable to substances whose virtues depend in any considerable degree upon readily volatilizable constituents. Campbell (*A. J. P.*, xlii, 17) proposed a method for doing away with the use of heat, which, however, although in some cases it may do well, cannot be relied upon for the complete exhaustion of all drugs. Sixteen troyounces of the powder are moistened with four to six fluidounces of the menstruum (usually alcohol), and packed in a glass funnel, a piece of sponge having previously been put in the beak of the funnel; the surface of the powder is covered with a disk of paper, and twelve fluidounces of menstruum poured on. When the sponge becomes saturated, the beak of the funnel is corked tightly and the whole set aside for four days, at the end of which time the percolation may be allowed to proceed without further addition of menstruum. J. W. Mill has called attention to the advantage of separating the powder into fine and coarse parts by means of sieves and packing the finer powder at the bottom.

H. Biroth (*Pharm.*, April, 1877) proposes the method which he termed "*insuccation*," for making non-alcoholic fluidextracts; the advantages claimed for it are simplicity and economy. Colaz prepared fluidextracts from fresh plants by bruising and crushing them, and placing the mass in a dialyzer suspended in 90 per cent. alcohol; when the dialysis is completed, the liquid is evaporated to free it from alcohol, the remaining aqueous liquid retaining the active constituents in the proportions in which they are found in the plant. (*Ph. Post*, xxix, 271.) Haussmann (*A. J. P.*, 1895, 291), after examining a large number of commercial fluidextracts, recorded his results in tabular form, and considered that there is great variation in the quality, due to deviation from pharmacopœial processes.

J. U. Lloyd proposes to recover the alcohol which remains absorbed by the residue after percolation, by mixing the wet residues with an equal bulk or less of dry sawdust, and then

percolating this with water. (*A. J. P.*, June, 1877.) Wm. M. Thomson, of Philadelphia, devised a very complete method of preparing fluidextracts on a large scale; the principles of his process are maceration and percolation *in vacuo*, and although the principles which have been applied have long been known, and similar apparatus used by Duffield and others, there are many useful practical points which merit a notice in detail. The percolators are egg-shaped, and made of tinned copper; they are capable of being tightly covered, and communicate by means of stopcocks above and below, and iron and stout rubber tubing, with a very efficient double acting air pump. The moistened powder is packed tightly in the percolator, and the cover securely bolted on. The stopcock in the cover is now opened, which communicates with the air pump and a partial vacuum created in the space above the moistened drug; the stopcock is now closed and another stopcock in the cover opened, which communicates by a tube with the reservoir containing the menstruum. The menstruum, of course, quickly penetrates the powder, taking the place of the interstitial air, and when the powder is saturated it is permitted to macerate *in vacuo* a sufficient length of time. To start percolation, a receiver is connected with the beak of the percolator, and, the air being exhausted from it, the percolate at once makes its appearance. When the flow slackens, air may be forced by the pump in the space above the powder, if desired, and the receiver again exhausted below. In this way, it can be seen, entire control of these powerful physical forces may be secured. The advantages are very apparent in preventing the loss of volatile principles and alcohol, while protecting from chemical change caused by exposure to the air. It is quite possible to make official fluidextracts without recourse to subsequent evaporation of weak percolate. For a cut of this apparatus, see *A. J. P.*, 1882.

Assaying Fluidextracts.—The number of assay processes for fluidextracts was materially increased in the U. S. P. (9th Rev.) for preparations made from alkaloidal drugs. The process in each case differs but slightly from the process used for the corresponding drug; they will be found in the succeeding pages under their appropriate headings.

A new method of assay for alkaloidal fluidextracts, especially adapted to the mydriatic leaf drugs in that the interfering chlorophyll is removed, making only one shaking out operation necessary, was proposed by LaWall (*J. A. Ph. A.*, 1912, 29), as follows: Place 25 Gm. of sodium chloride in a 100 mil graduated cylinder, with water sufficient to make 85 mils. Agitate well for 1 minute, then pour upon a dry filter and collect 50 mils of clear filtrate, which can be shaken out as directed in the final shake out of the ordinary assay process, using the solvent directed for the particular drug which is being assayed. The method does not work with cinchona, guarana or other drugs containing large amounts of alkaloids in the form of cinchotannates.

Fluidextracts U. S. P. IX.

* "The fluidextracts of this Pharmacopœia, with few exceptions, may be classified according to the menstrua used in the extraction of the drugs and the processes of manufacture employed. Several drugs require special manipulation to obtain satisfactory fluidextracts, and for these appropriate formulas have been devised and are printed in full in the text. The following type processes are described, and in each formula the process to be used is designated by reference to the type process:

"**Type Process A**—In this class are included those fluidextracts that are made with a menstruum of alcohol or a mixture of alcohol and water by the usual process of percolation. Moisten *one thousand grammes* [or 35 ounces av., 120 grains] of the powdered drug directed with a sufficient quantity of the prescribed menstruum to render it evenly and distinctly damp and to maintain it so, after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator and add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more menstruum until the drug is exhausted. Reserve the first *eight hundred and fifty mils* [or 28 fluidounces, 356 minims] of the percolate (unless otherwise specified in the formula); recover the alcohol from the remainder and concentrate the residue to a soft extract at a temperature not exceeding 60° C. (140° F.); dissolve this in the reserved portion, mix thoroughly, and finally add a sufficient quantity of the menstruum to obtain *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] or the volume determined by calculation from the assay.

"**Type Process B**—In this class are included those fluidextracts in which glycerin or an acid is used in the extraction and two menstrua are successively employed. Menstruum I contains the glycerin or acid in definite proportion to the amount of the drug, and Menstruum II, a mixture of alcohol and water intended for completing the exhaustion of the drug. Moisten *one thousand grammes* [or 35 ounces av. 120 grains] of the powdered drug directed with a sufficient quantity of the prescribed Menstruum I, to render it evenly and distinctly damp and to maintain it so after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator, add the remainder of Menstruum I, and, when this has just disappeared from the surface, gradually add Menstruum II, constantly maintaining a stratum of liquid above the drug. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours, and then allow the percolation to proceed slowly, gradu-

ally adding Menstruum II until the drug is exhausted. Reserve the first *eight hundred and fifty mils* [or 28 fluidounces, 356 minims] of the percolate (unless otherwise specified in the formula); recover the alcohol from the remainder and concentrate the residue to a soft extract at a temperature not exceeding 60° C. (140° F.); dissolve this in the reserved portion, mix thoroughly, and finally add a sufficient quantity of Menstruum II to obtain *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] or the volume determined by calculation from the assay.

"**Type Process C**—The process of *fractional* or *divided percolation.* This is especially recommended for drugs containing volatile ingredients or constituents injured by exposure to heat. This process may likewise be used as an alternative process in the formulas in which Type Process A is directed. Divide *one thousand grammes* [or 35 ounces av., 120 grains] of the powdered drug directed into three portions of *five hundred grammes* [or 17 ounces av. 279 grains] *three hundred grammes* [or 10 ounces av. 255 grains] and *two hundred grammes* [or 7 ounces av. 24 grains] respectively. Moisten the first portion of the drug (500 Gm.) [or 17 ounces av., 279 grains] with a sufficient quantity of the prescribed menstruum to render it evenly and distinctly damp and to maintain it so after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator and add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours and then allow the percolation to proceed slowly, gradually adding more of the menstruum. Reserve the first *two hundred mils* [or 6 fluidounces, 366 minims] of percolate and continue the process until the additional percolate measures *fifteen hundred mils* [or 50 fluidounces, 345 minims], the latter being collected in successive portions of *three hundred mils* [or 10 fluidounces, 69 minims] each.

"Moisten the second portion of the powdered drug (300 Gm.) [or 10 ounces av. 255 grains] with a sufficient quantity of the percolate collected in the preceding operation immediately after the reserved portion, to render it evenly and distinctly damp and to maintain it so after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator and macerate and percolate as directed for the first part of the drug, using as menstruum the several portions of percolate from the preceding operation in the order in which they have been collected, and, if this be insufficient, follow with some of the original menstruum. Reserve the first *three hundred mils* [or 10 fluidounces, 69 minims] of percolate and continue the process until the additional percolate measures *eight hundred mils* [or 27 fluidounces, 24 minims] collecting the weaker percolate in successive portions of *two hundred mils* [or 6 fluidounces, 366 minims] each.

"Moisten the third portion of the powdered drug (200 Gm. [or 7 ounces av. 24 grains]) with a sufficient quantity of the percolate collected in the preceding operation immediately after the reserved portion, to render it evenly and distinctly damp and to maintain it so after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator and macerate and percolate as before, using as menstruum the several portions of percolate from the preceding operation in the order in which they have been collected, and, if this be insufficient, follow with more of the original menstruum. Collect *five hundred mils* [or 16 fluidounces, 435 minims] of percolate and mix this with the two portions previously reserved so as to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of finished fluidextract.

"When Type Process C is directed for fluidextracts which are adjusted by assay to a definite alkaloidal standard, collect only *four hundred and twenty mils* [or 14 fluidounces, 97 minims] of percolate from the third portion of drug instead of the *five hundred mils* [or 16 fluidounces, 435 minims] directed above. Mix this percolate with the two portions previously reserved, assay a portion of the mixture and then adjust its volume, by the addition of the menstruum directed, so that each *one hundred mils* [or 3 fluidounces, 183 minims] of finished fluidextract will contain the prescribed amount of alkaloid.

"**Type Process D**—In this class are included those fluidextracts in which extraction is effected by infusion and percolation with boiling water, alcohol being added to the concentrated liquid as a preservative.

"In the preparation of fluidextracts by either Process A, B, or C, the rate of percolation must be carefully controlled and, for the quantities directed in the formulas of the Pharmacopœia, the flow should not exceed ten drops per minute until the reserved percolate is collected, and twenty drops per minute thereafter. As a rule *one thousand grammes* [or 35 ounces av., 120 grains] of powdered drug may be exhausted by percolation with sufficient menstruum to yield *three thousand mils* [or 101 fluidounces, 212 minims] of percolate.

"Fluidextracts should be kept in tightly-stoppered containers for one month and then, if perfectly clear, they should be stored in amber-colored bottles protected from sunlight and extremes of temperature. If sedimentation has occurred the clear portion should be decanted, the remainder filtered and the liquids thoroughly mixed before storing.

"The percentage of alcohol in fluidextracts made by type processes A, B, or C is variable and always less than that in the menstruum employed, due, among other causes, to loss of alcohol by evaporation during manufacture, to the presence of a variable proportion of water in the air-dried drug, and to the extraction from the drug of its soluble constituents, which also often vary greatly in different lots of the same drug. The percentage of alcohol in the finished

product can therefore only be ascertained by an actual determination (see Determination of Alcohol in Official Preparations, Part III, No. 14). To *one thousand grammes* [or 35 ounces av., 120 grains] of the ground drug add *five thousand mils* [or 169 fluidounces, 33 minims] of boiling water, mix thoroughly and allow it to macerate in a covered container for two hours in a warm place. Then transfer the moist drug to a tinned or enameled metallic percolator and allow percolation to proceed, gradually adding boiling water until the drug is exhausted. Evaporate the percolate on a water bath or steam bath to the volume specified and when cold add the alcohol directed and mix thoroughly." *U. S.*

FLUIDEXTRACTUM ACONITI. U. S.

FLUIDEXTRACT OF ACONITE Fldext. Aconit.

(flū-ĭd-ĕx-trăc'tŭm ăc-ō-nī'tī)

" *One hundred mils* of Fluidextract of Aconite yields not less than 0.45 Gm. nor more than 0.55 Gm. of the ether-soluble alkaloids of aconite. If assayed biologically the minimum lethal dose should not be greater than 0.00004 mil for each gramme of body weight of guinea-pig." *U. S.*

Fluid Extract of Aconite Root; Extrait liquide de Racine d'Aconit, *Fr.*; Flüssiges Eisenhutknollenextrakt, *G.*

* " Aconite, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains].

" Prepare a Fluidextract by Type Process C, as modified for alkaloidal drugs (see page 484), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum and adjusting the volume of the finished Fluidextract so that each *one hundred mils* contains 0.5 Gm. of the ether-soluble alkaloids of aconite." *U. S.*

" **Assay.**—From a pipette drop 15 mils of Fluidextract of Aconite evenly over the surface of 15 Gm. of purified sawdust (see Part III) and evaporate to dryness at a temperature not exceeding 75° C. (167° F.). Transfer the mixture to a 250 mil flask, add 150 mils of ether, and proceed as directed under *Belladonnæ Radix,* page 222, fifth line of the Assay, modifying the process there given by using the ammonia water with a small quantity of distilled water to rinse the dish in which the mixture was evaporated, and ether only in the final shaking out of the alkaloids.

" Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 64.539 milligrammes of the ether-soluble alkaloids of aconite.

" For an alternative method of assaying Fluidextract of Aconite see Biological Assays (Part III)." *U. S.* (See *Aconitum.*)

This preparation of aconite root was found useful by Procter as a basis for making the other preparations of aconite,—the plaster, extract, tincture, or liniment. The fluidextract is of a bright deep reddish-brown color. It will doubtless be frequently employed as an addition to liniments for obtaining the peculiar effects of aconite.

Dose, one-half to one minim (0.03–0.06 mil), but on account of its very powerful character it should always be used with caution, beginning with the smallest dose.

Off. Prep.—Linimentum Aconiti et Chloroformi, *N. F.*

FLUIDEXTRACTUM AROMATICUM. U. S.

AROMATIC FLUIDEXTRACT Fldext. Aromat.

(flū-ĭd-ĕx-trăc'tŭm ăr-ō-măt'ĭ-cŭm)

Extrait liquide aromatique, *Fr.*; Flüssiges Aromatisches Extrakt, *G.*

* " Aromatic Powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process C (see page 484), using alcohol as the menstruum." *U. S.*

This is a valuable fluidextract; it is an excellent aromatic in concentrated form, and will be found very useful not only as an addition to liquids when an aromatic is desired, but its concentrated form permits its use in small quantities with dry powders, like pepsin, bismuth subnitrate, etc., when desired for administration. It is rarely used alone.

Dose, from ten to twenty minims (0.6–1.3 mils), diluted with water, or dropped on sugar.

FLUIDEXTRACTUM ASPIDOSPERMATIS. U. S.

FLUIDEXTRACT OF ASPIDOSPERMA Fldext. Aspidosp. [Fluidextract of Quebracho]

(flū-ĭd-ĕx-trăc'tŭm ăs-pĭ-dō-spēr-mā'tĭs)

* "Aspidosperma, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see page 483), using a mixture of *one hundred and ten mils* [or 3 fluidounces, 345 minims] of glycerin, *six hundred and seventy mils* [or 22 fluidounces, 315 minims] of alcohol and *two hundred and twenty mils* [or 7 fluidounces, 211 minims] of water as Menstruum I, and a mixture of *two volumes* of alcohol and *one volume* of water as Menstruum II." *U. S.* (See *Aspidosperma,* page 204.)

Dose, one fluidrachm (3.75 mils).

FLUIDEXTRACTUM AURANTII AMARI. U. S.

FLUIDEXTRACT OF BITTER ORANGE PEEL Fldext. Aurant. Amar.

(flū-ĭd-ĕx-trăc'tŭm âu-răn'tĭ-ī ă-mā'rī)

Extrait liquide d'Ecorce d'Orange amére, *Fr.*; Flüssiges Pomeranzenschalenextrakt, *G.*

* "Bitter Orange Peel, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process C (see page 484), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum." *U. S.*

This fluidextract is useful as a tonic; when dry, the bitter orange peel having very little oil present, there is necessarily little agreeable orange flavor to the fluidextract. Monroe Bond recommends a *Fluidextract of Sweet Orange*

Peel, made with a menstruum of seven parts of alcohol and one of glycerin. (*A. J. P.,* 1873, p. 482.)

Dose, fifteen to thirty minims (0.9–1.8 mils).

Off. Prep.—Vinum Rhei Compositum, *N. F.*

EXTRACTUM BELÆ LIQUIDUM. Br.

LIQUID EXTRACT OF BAEL

(ĕx-trăc'tŭm bē'læ lĭq'uĭ-dŭm)

"Bael Fruit, bruised, 1000 *grammes;* Chloroform Water, 15000 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Macerate the bruised Bael Fruit for twelve hours in five thousand *millilitres* of the Chloroform Water; pour off and reserve the clear liquid; repeat the maceration a second and a third time for one hour in each case, using for each maceration five thousand *millilitres* of the Chloroform Water; press the marc; strain the mixed liquids through flannel. Evaporate to seven hundred and fifty *millilitres;* cool; add sufficient of the Alcohol to produce the required volume; filter." *Br.*

This represents whatever therapeutic virtues may reside in Bael Fruit. (See *Belæ Fructus,* page 219.)

Dose, one to two fluidrachms (3.75–7.5 mils).

FLUIDEXTRACTUM BELLADONNÆ RADICIS. U. S. (Br.)

FLUIDEXTRACT OF BELLADONNA ROOT

Fldext. Bellad. Rad.

(flŭ-ĭd-ĕx-trăc'tŭm bĕl-lą-dŏn'næ rą'dĭ-cīs)

"*One hundred mils* of Fluidextract of Belladonna Root yields not less than 0.405 Gm. nor more than 0.495 Gm. of the alkaloids of belladonna root." *U. S.*

"Liquid Extract of Belladonna contains in 100 millilitres, 0.75 gramme of the alkaloids of Belladonna Root." *Br.*

Extractum Belladonnæ Liquidum, *Br.,* Liquid Extract of Belladonna; Extrait liquide de Racine de Belladone, *Fr.;* Flüssiges Tollkirschenwurzelextrakt, *G.*

* "Belladonna Root, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]." *U. S.*

* "Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *five volumes* of alcohol and *one volume* of water as the menstruum, and reserving the first *eight hundred mils* [or 27 fluidounces, 24 minims] of the percolate.

"After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough menstruum to make *one hundred mils* of the finished Fluidextract contain 0.45 Gm. of the alkaloids of belladonna root." *U. S.*

"Belladonna Root, in No. 20 powder, 1000 *grammes;* Alcohol (90 per cent.), Distilled Water, of each *a sufficient quantity.* Exhaust the Belladonna Root with a mixture of seven volumes of the Alcohol and one volume of Distilled Water by the *repercolation process* until from every three *grammes* of the Root one *millilitre* of strong percolate has been obtained." *Br.*

"**Assay.**—Introduce 10 mils of Fluidextract of Belladonna Root into a separator and add 10 mils of distilled water and 2 mils of ammonia water. Completely extract the alkaloids by shaking out repeatedly with chloroform and then extract the alkaloids from the chloroform solution by shaking out repeatedly with weak sulphuric acid until the alkaloids are completely removed. Collect the acid washings in a separator, add ammonia water until the solution is decidedly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with chloroform. Evaporate the combined chloroform washings to dryness, dissolve the alkaloids from the residue in exactly 5 mils of tenth-normal sulphuric acid V.S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., using cochineal T.S. as indicator.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the alkaloids of belladonna root (see Proximate Assays, Part III)." *U. S.*

"Determine the proportion of alkaloids in this strong percolate by the following process: Introduce into a separator 10 *millilitres* of the strong percolate, 50 *millilitres* of *water,* 2 *millilitres* of *diluted sulphuric acid,* and 10 *millilitres* of *chloroform.* Shake vigorously, set aside until complete separation has taken place, draw off the lower layer, and wash it with two successive portions, each of 10 *millilitres,* of *water* acidified with *diluted sulphuric acid.* Add the washings to the upper layer left in the separator. Make the mixture distinctly alkaline with *solution of ammonia,* and extract the alkaloids by shaking with three successive portions, each of 10 *millilitres* of *chloroform.* Mix the chloroformic solutions, shake with 10 *millilitres* of *water,* allow separation to take place, draw off the lower layer into a beaker, and set aside for the chloroform to evaporate. Heat the residue on a water-bath for thirty minutes, add 10 *millilitres* of *N/20 solution of sulphuric acid,* warm gently until dissolved, and titrate back with *N/20 solution of sodium hydroxide, tincture of cochineal* being used as indicator. Deduct the number of *millilitres* of alkaline solution required from 10; the remainder, multiplied by 0.01446, gives the number of *grammes* of the alkaloids contained in 10 *millilitres* of the strong percolate. To the remainder of the strong percolate add sufficient of the alcoholic menstruum to produce a Liquid Extract of Belladonna containing 0.75 *gramme* of the alkaloids of Belladonna Root in 100 *millilitres.* Examined by the foregoing process, Liquid Extract of Belladonna is found to contain in 100 millilitres 0.75 gramme of the alkaloids of Belladonna Root. *Limit of error* 0.05 gramme in excess or defect. This Liquid Extract contains 0.75 gramme of the alkaloids of Belladonna Root in 100 millilitres; 110 minims contains ¾ grain." *Br.*

The British liquid extract, 1914, represented several radical improvements in British pharmacy,—*i.e.*, the use of repercolation with absence of heat in the process, and standardization, thus making the end product bear a definite relation towards the quantity of active constituents found in the root (0.75 per cent.). It is based upon the formula proposed by R. A. Cripps. (*P. J.*, 1895, 795.) It will be observed that the alkaloidal standards of the U. S. and Br. Pharmacopœias are not identical; the U. S. fluidextract is made from the standardized drug (belladonna root) (0.45 per cent.); the British liquid extract is made from the *unstandardized* drug and hence the standard for the liquid extract can be made stronger (0.75 per cent.). The fluidextract of the root is a good preparation, of reddish-brown color, very different in appearance from the deep-green fluidextract of the leaves which is often seen in the market.

Dose, from one to two minims (0.06–0.12 mil) of the British liquid extract, not more than one minim (0.06 mil).

Off. Prep.—Emplastrum Belladonnæ, *Br.;* Extractum Belladonnæ Siccum, *Br.;* Linimentum Belladonnæ, *U. S., Br.;* Unguentum Belladonnæ, *Br.*

FLUIDEXTRACTUM BUCHU. U. S.

FLUIDEXTRACT OF BUCHU Fldext. Buchu.

(flū-ĭd-ĕx-trăc'tŭm bū'chū)

Extrait liquide de Bucco, *Fr.;* Flüssiges Buccoextrakt, *G.*

* "Buchu, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using alcohol as the menstruum." *U. S.*

The menstruum selected for this fluidextract has been alcohol, although experience has shown that with the weaker alcohol used in the U. S. P. VIII formula it was possible to percolate buchu leaves satisfactorily. We prefer as a menstruum that of the U. S. P. VIII, *i.e.*, alcohol 3, water 1.

This fluidextract is of a dark green color, and shows in a high degree the sensible properties of the leaves. It acquires the odor of mint when long kept, showing that some change takes place in its volatile oil. This fluidextract affords the best means at our command for the exhibition of buchu.

Dose, thirty minims to a fluidrachm (1.8–3.75 mils), three to five times a day.

Off. Prep.—Elixir Buchu, *N. F.*

FLUIDEXTRACTUM CANNABIS. U. S.

FLUIDEXTRACT OF CANNABIS Fldext. Cannab. [Fluidextractum Cannabis Indicæ, U. S. P. VIII]

(flū-ĭd-ĕx-trăc'tŭm căn'nă-bĭs)

"When assayed biologically Fluidextract of cannabis produces incoördination when administered to dogs in a dose of not more than 0.03 mil per kilogramme of body weight." *U. S.*

Extrait liquide de Chanvre Indien, *Fr.;* Flüssiges Indisch-Hanfextrakt, *G.*

* "Cannabis, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using alcohol as the menstruum. After dissolving the soft extract in the reserve liquid, assay a portion as directed below and from the result thus obtained adjust the volume of the finished Fluidextract to conform to the above biological standard.

"**Assay.**—Proceed as directed under *Cannabis* and also under Biological Assays, Part III." *U. S.*

Uses.—The fluidextract of cannabis represents the therapeutic virtues of that drug in a convenient form. The smallness of the dose is an advantage over the tincture and many believe that the extract is injured by the evaporation. Unfortunately the fluidextract, even when properly made, does not retain its powers and after a year is almost worthless. For this reason the commercial samples vary so greatly in power that it is impossible to assign the proper dose. The only satisfactory way to use it is to start in with doses of one or two minims, increasing each day until some effect is obtained.

Dose, one to four minims (0.06–0.25 mil).

Off. Prep.—Collodium Salicylici Compositum, *N. F.*

FLUIDEXTRACTUM CASCARÆ SAGRADÆ. U. S. (Br.)

FLUIDEXTRACT OF CASCARA SAGRADA Fldext. Casc. Sagr. [Fluidextractum Rhamni Purshianæ, U. S. VIII]

(flū-ĭd-ĕx-trăc'tŭm căs-căr'æ są-grăd'æ)

Extractum Cascaræ Sagradæ Liquidum, *Br.;* Liquid Extract of Cascara Sagrada; Extrait liquide de Cascara Sagrada, *Fr.;* Flüssiges Cascara-Sagrada-extrakt, *G.*

* "Cascara Sagrada, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]. Prepare a Fluidextract by Type Process D (see page 484). Evaporate the aqueous percolate to *seven hundred and fifty mils* [or 25 fluidounces, 173 minims] and when cold gradually add the alcohol and, if necessary, sufficient water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.* "Cascara Sagrada, in No. 20 powder, 1000 *grammes;* Alcohol (90 per cent.), 250 *millilitres;* Distilled Water, sufficient to produce 1000 *millilitres.* Exhaust the Cascara Sagrada with the Distilled Water by the *percolation process;* evaporate the percolate to six hundred *millilitres;* add the Alcohol previously mixed with one hundred and fifty *millilitres* of the Distilled Water, or with sufficient to produce the required volume." *Br.*

This fluidextract is a good preparation, but the aromatic fluidextract is more largely used.

The emodin strength of this and similar preparations of cascara, which has been arbitrarily set by most manufacturers at 1.50 grammes in each 100 mils of the fluidextract, may be estimated by the method of Vanderkleed and Ewe (*Proc. Pa. Pharm. Assoc.*, 1913, p. 325.)

Dose, fifteen minims to one fluidrachm (0.9–3.75 mils).

Off. Prep.—Extractum Cascaræ Sagradæ Siccum, *Br.;* Syrupus Cascaræ Aromaticus, *Br.*

FLUIDEXTRACTUM CASCARÆ SAGRADÆ AROMATICUM. U. S.

AROMATIC FLUIDEXTRACT OF CASCARA SAGRADA
Fldext. Casc. Sagr. Arom. [Fluidextractum Rhamni Purshianæ Aromaticum, U. S. VIII]

(flū-ĭd-ĕx-trăc'tŭm căs-căr'æ są-grăd'æ ăr-ō-măt'ĭ-cŭm)

Tasteless Fluidextract of Cascara Sagrada; Extrait liquid Aromatique de Cascara Sagrada, *Fr.;* Bitterloses flüssiges Cascara-Sagradaextrakt, *G.*

* "Cascara Sagrada, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Magnesium Oxide, *one hundred and twenty-five grammes* [or 4 ounces av., 179 grains]; Pure Extract of Glycyrrhiza, *forty grammes* [or 1 ounce av., 180 grains]; Glycerin, *two hundred mils* [or 6 fluidounces, 366 minims]; Alcohol, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]; Benzosulphinide, *one gramme* [or 15 grains]; Oil of Anise, *two and five-tenths mils* [or 40 minims]; Oil of Cinnamon, *two-tenths of a mil* [or 3 minims]; Oil of Coriander, *one-tenth of a mil* [or 1½ minims]; Methyl Salicylate, *two-tenths of a mil* [or 3 minims]; Boiling Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Thoroughly mix the cascara sagrada with the magnesium oxide, moisten the mixture with *two thousand mils* [or 67 fluidounces, 301 minims] of boiling water, set it aside for two hours, stirring occasionally, and then pack it in a percolator. Now pour on boiling water and allow the percolation to proceed until the drug is exhausted. Evaporate the percolate to *five hundred mils* [or 16 fluidounces, 435 minims] and while yet warm dissolve in it the extract of glycyrrhiza. When cold, add the glycerin, then the alcohol in which the benzosulphinide and the oils have been dissolved, and finally sufficient water to make the Fluidextract measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

An aromatic fluidextract was introduced into the U. S. P. VIII for the first time. It is given as a laxative, the object of the addition of magnesium oxide is to destroy the bitter taste of the cascara sagrada. Lime is sometimes used instead of magnesia but it has been shown that lime acts injuriously upon the laxative principles of cascara sagrada.

Dose, fifteen minims to one fluidrachm (0.9–3.75 mils).

Off. Prep.—Elixir Cascaræ Sagradæ, *N. F.;* Elixir Cascaræ Sagradæ Compositum, *N. F.*

FLUIDEXTRACTUM CIMICIFUGÆ. U. S.

FLUIDEXTRACT OF CIMICIFUGA
Fldext. Cimicif. [Fluidextract of Black Cohosh, Fluidextract of Black Snakeroot]

(flū-ĭd-ĕx-trăc'tŭm cĭm-ĭ-cĭf'ŭ-gæ)

Extractum Cimicifugæ Liquidum, *Br.* 1898, Liquid Extract of Cimicifuga; Liquid Extract of Actæa Racemosa; Extrait liquide d'Actée à Grappes, *Fr.;* Flussiges Cimicifugaextrakt, *G.*

* "Cimicifuga, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using alcohol as the menstruum." *U. S.*

There probably cannot be two opinions about the menstruum, although it has been asserted that a good fluidextract can be made with a menstruum of three parts alcohol and one part water. The probabilities are, however, that a portion of the resinous principle would precipitate on standing. This fluidextract is of a deep reddish-brown color, and thoroughly represents the drug.

Dose, from ten to thirty minims (0.6–1.9 mils).

Off. Prep.—Elixir Sodii Salicylatis Compositum, *N. F.;* Syrupus Cimicifugæ Compositus, *N. F.*

FLUIDEXTRACTUM CINCHONÆ. U. S. (Br.)

FLUIDEXTRACT OF CINCHONA Fldext. Cinchon. [Fluidextract of Calisaya Bark]

(flū-ĭd-ĕx-trăc'tŭm cĭn-chō'næ)

"*One hundred mils* of Fluidextract of Cinchona yields not less than 4 Gm. nor more than 5 Gm. of the alkaloids of cinchona." *U. S.* "Liquid Extract of Cinchona contains in 100 millilitres 5 grammes of the alkaloids of Red Cinchona Bark." *Br.*

Extractum Cinchonæ Liquidum, *Br.,* Liquid Extract of Cinchona; Extractum Chinæ Calisayæ Fluidum; Extrait liquide de Quinquina jaune, *Fr.;* Flüssiges Kalisayarinden extrakt, Flüssiges Chinaextrakt, *G.*

* "Cinchona, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see page 483), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *one hundred mils* [or 3 fluidounces, 183 minims] of diluted hydrochloric acid and *eight hundred mils* [or 27 fluidounces, 24 minims] of alcohol as Menstruum I and a mixture of *four volumes* of alcohol and *one volume* of water as Menstruum II. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid, and dilute this with enough of Menstruum II to make each *one hundred mils* of the finished Fluidextract contain 4.5 Gm. of the total alkaloids of cinchona." *U. S.*

"Red Cinchona Bark, in No. 60 powder, 1000 *grammes;* Hydrochloric Acid, 31 *millilitres;* Glycerin, 125 *millilitres;* Alcohol (90 per cent.), Distilled Water, of each *a sufficient quantity.* Mix the Red Cinchona Bark with five thousand *millilitres* of the Distilled Water, to which the Hydrochloric Acid and Glycerin have been added; set aside in a covered vessel for forty-eight hours, stirring frequently; transfer to a percolator; when the liquid ceases to pass continue the percolation with Distilled Water until the percolate ceases to give a precipitate with excess of *solution of sodium hydroxide.* Evaporate the percolate in a porcelain or enamelled

iron vessel at a temperature not exceeding 85° C. (185° F.), until it is reduced to one thousand *millilitres.*" *Br.*

Assay of Fluidextract of Cinchona.—"From a pipette drop 5 mils of Fluidextract of Cinchona evenly over the surface of 10 Gm. of purified sawdust (see Part III) and evaporate it to dryness at a temperature not exceeding 80° C. (176° F.). Transfer the mixture to a 500 mil flask, and proceed as directed under *Cinchona,* third line of the Assay, beginning with the words 'and add,' modifying the process there given by increasing the amount of ammonia water to 10 mils, using this in divided portions to rinse the dish in which the mixture was evaporated, and adding the rinsings to the flask.

"The weight of the residue is the amount of total alkaloids from 4 mils of Fluidextract of Cinchona." *U. S.*

British Assay.—"Determine the proportion of alkaloids in the liquid product by the following process: Transfer 5 *millilitres* to a stoppered glass separator; add 15 *millilitres* of *benzolated amylic alcohol* and 10 *millilitres* of *N/1 alcoholic solution of potassium hydroxide;* shake well, set aside in a warm place for a few minutes, shaking occasionally, and then allow the liquids to separate; pour off the clear upper layer into a second separator and repeat the shaking with two further portions of 15 and 10 *millilitres* of *benzolated amylic alcohol.* Shake the mixed alcoholic liquids with two portions, each of 5 *millilitres,* of *water,* and reject the aqueous liquid; then shake vigorously with a warm mixture of 12 *millilitres* of *diluted hydrochloric acid* and 60 *millilitres* of *water,* using three successive portions of 30, 30, and 12 *millilitres,* and drawing off the acid liquids into a separator. To this acid liquid add 15 *millilitres* of *chloroform* and distinct excess of *solution of ammonia,* shake vigorously, allow the liquids to separate and draw off the chloroformic layer into a tared dish; repeat the shaking and separating with further portions, each of 10 *millilitres,* of *chloroform* until the aqueous liquid, after acidification with *diluted sulphuric acid,* gives no further precipitate with *solution of potassio-mercuric iodide.* Add the chloroformic solutions to that in the dish, allow the chloroform to evaporate slowly; dry the residue in the dish at a temperature of about 110° C. (230° F.) and weigh. The weight of the residue is that of the total alkaloids in 5 *millilitres* of the liquid product. Having thus ascertained the alkaloidal strength of the liquid product, bring every volume of it containing 5 *grammes* of total alkaloids to eighty-five *millilitres,* either by evaporation or by dilution with Distilled Water as may be necessary, add twelve and a half *millilitres* of the Alcohol, and finally sufficient Distilled Water to produce one hundred *millilitres* of the Liquid Extract. Examined by the foregoing process, Liquid Extract of Cinchona is found to contain in 100 *millilitres* 5 grammes of the alkaloids of Red Cinchona Bark. *Limit of error* 0.2 gramme in excess or defect. This Liquid Extract contains 5 grammes of the alkaloids of Red Cinchona Bark in 100 millilitres; 110 minims contain 5 grains." *Br.*

The process for this fluidextract was changed in the U. S. P. IX by the addition of diluted hydrochloric acid to the menstruum of alcohol, glycerin and water.

The U. S. fluidextract of cinchona is a moderately thin, dark reddish-brown, translucent fluid, of a bitter, astringent taste.

Dose, five to twenty minims (0.3–1.3 mils).

FLUIDEXTRACTUM COLCHICI SEMINIS. U. S.

FLUIDEXTRACT OF COLCHICUM SEED
Fldext. Colch. Sem.

(flŭ-ĭd-ĕx-trăc'tŭm cŏl'çhĭ-cī sĕm'ĭ-nĭs)

"*One hundred mils* of Fluidextract of Colchicum Seed yields not less than 0.36 Gm. nor more than 0.44 Gm. of colchicine." *U. S.*

Extrait liquide de Semences de Colchique, *Fr.;* Flüssiges Zeitlosensamenextrakt, *G.*

* "Colchicum Seed, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Purified Petroleum Benzin, *a sufficient quantity.* Pack the colchicum seed in a cylindrical percolator and slowly percolate with purified petroleum benzin until a few drops of the percolate leave no greasy stain when evaporated on a piece of filter paper. Reject the benzin solution, remove the powder from the percolator and dry it by exposure to the air. Then proceed to make the Fluidextract by Type Process A (see page 483), using a mixture of *two volumes* of alcohol and *one volume* of water as the menstruum. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid, and dilute this with enough menstruum to make each *one hundred mils* of the finished Fluidextract contain 0.4 Gm. of colchicine." *U. S.*

"Assay of Fluidextract of Colchicum Seed.—Introduce 15 mils of Fluidextract of Colchicum Seed into a 500 mil flask, add 10 mils of solution of lead subacetate, previously diluted with 35 mils of distilled water, shake the mixture thoroughly, then add 240 mils of distilled water, again agitate the mixture and proceed as directed under *Colchici Semen,* page 371, ninth line of the Assay." *U. S.*

The use of glycerin in the former U. S. fluidextract was objectionable, as the fixed oil contained in the seeds was always thrown out of solution, and was usually found floating on the fluidextract, rendering the preparation unsightly. The present formula, U. S. P. IX, is an improvement, as the fixed oil is removed by the benzin treatment. L. I. Morris (*A. J. P.,* 1881, 7) believes that it is unnecessary to grind the colchicum seeds, and that if the whole seeds are digested with diluted alcohol at 80° C. (176° F.) the colchicine is easily extracted.

Dose, two to eight minims (0.12–0.5 mil).

Off. Prep.—Vinum Colchici Seminis. *N. F.*

FLUIDEXTRACTUM DIGITALIS. U. S.

FLUIDEXTRACT OF DIGITALIS Fldext. Digital.

(flū-ĭd-ĕx-trăc'tŭm dĭg-ĭ-tă'lĭs)

"If assayed biologically the minimum lethal dose should not be greater than 0.0006 mil of the Fluidextract, or the equivalent in Fluidextract of 0.0000005 Gm. of ouabain, for each gramme of body weight of frog." *U. S.*

Extrait liquide de Digitale, *Fr.;* Flüssiges Fingerhutkrautextrakt, Flüssiges Digitalisextrakt, *G.*

* "Digitalis, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *five volumes* of alcohol and *one volume* of water as the menstruum."

Assay.—For a method of assaying Fluidextract of Digitalis, see *Digitalis,* and also Biological Assays, Part III.

The increase in the proportion of alcohol in this fluidextract as compared to that of the U. S. VIII is a great advantage. Not only does this menstruum extract the activities of the drug more thoroughly, but with the low percentage of alcohol in the former fluidextract there was marked deterioration of the preparation when kept. (See Hamilton, *A. J. P.,* Feb., 1914.)

Dose, one-half to two minims (0.03–0.12 mil).

FLUIDEXTRACTUM ERGOTÆ. U. S. (Br.)

FLUIDEXTRACT OF ERGOT Fldext. Ergot.
[Secalis Cornuti Extractum Fluidum P. I.]

(flū-ĭd-ĕx-trăc'tŭm ẹr'gọ-tæ)

Extractum Ergotæ Liquidum, *Br.;* Liquid Extract of Ergot; Extrait liquide de Seigle ergoté, *Fr.;* Extractum Secalis Cornuti fluidum, *P. G.;* Mutterkorn-Fluidextrakt, Flüssiges Mutterkornextrakt, *G.*

* "Ergot, recently ground and in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see page 483), using a mixture of *twenty mils* [or 325 minims] of hydrochloric acid and *nine hundred and eighty mils* [or 33 fluidounces, 66 minims] of diluted alcohol as Menstruum I, and diluted alcohol as Menstruum II." *U. S.* "Ergot, crushed, 1000 *grammes* Distilled Water, 7500 *millilitres;* Alcohol (90 per cent.), 375 *millilitres.* Macerate the crushed Ergot with five thousand *millilitres* of the Distilled Water for twelve hours; strain; repeat the maceration with the remainder of the Distilled Water; press; strain; evaporate the mixed liquids to seven hundred *millilitres;* when cold, add the Alcohol; set aside for an hour; filter. The product measures about one thousand *millilitres.*" *Br.*

The Br. preparation is greatly inferior to the U. S. because of the use of an aqueous menstruum. It has been shown by Barger and Dale (*Biochem. J.,* 1907, ii, p. 286) that the Br. liquid extract is almost completely lacking in the characteristic alkaloid, ergotoxin.

Uses.—An increase in the percentage of alcohol used in this fluidextract would have been an advantage, as some of the active principles of ergot are practically insoluble in water. Great care should be observed in the evaporation of the second portion of the percolate not to exceed the official temperature, 60° C. (140° F.) as the activity of ergot is seriously lessened by heating.

The U. S. fluidextract, when fresh, well represents the activity of ergot and is probably the best preparation of ergot on the market. Unfortunately, however, as shown by H. C. Wood, Jr. (*A. J. P.,* 1911, 172), it is subject to rapid deterioration. (For literature on this subject, see Eberhardt and Eldred, *J. A. Ph. A.,* 1914, iii, 38.) This loss of potency is accelerated by exposure to the air and the preparation should be stored in small containers which are kept tightly corked until used. Pittenger and Vanderkleed assert that by keeping the fluidextract in hermetically sealed vacuum tubes it will retain its activity almost indefinitely; but the figures they give do not entirely confirm their claim. Certainly the common custom of buying fluidextract of ergot, for retail dispensing, and pouring out a little now and then as it may be called for, on prescriptions, can not be too severely condemned. Under such conditions the preparation may lose 50 per cent. of its power in less than six months.

Dose, from half a fluidrachm to two fluidrachms (1.8–8.0 mils).

FLUIDEXTRACTUM ERIODICTYI. U. S.

FLUIDEXTRACT OF ERIODICTYON Fldext. Eriodict.
[Fluidextract of Yerba Santa]

(flū-ĭd-ĕx-trăc'tŭm ĕr-ĭ-ō-dĭc'tỹ-ī)

Extrait liquide d'Eriodictyon, *Fr.;* Flüssiges Eriodictyonextrakt, *G.*

* "Eriodictyon, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *four volumes* of alcohol and *one volume* of water as the menstruum, and reserving the first *eight hundred mils* [or 27 fluidounces, 24 minims] of percolate." *U. S.*

For a process for Aromatic Fluidextract of Yerba Santa, see *U. S. D.,* 19th ed., p. 539.

This fluidextract has a dark brownish-green color, and has proven a valuable addition.

Dose, from fifteen minims to a fluidrachm (0.9–3.75 mils).

Off. Prep.—Elixir Eriodictyi Aromaticum, *N. F.;* Syrupus Eriodictyi Aromaticus, *N. F.*

FLUIDEXTRACTUM EUCALYPTI. U. S.

FLUIDEXTRACT OF EUCALYPTUS
Fldext. Eucalypt.

(flū-ĭd-ĕx-trăc'tŭm eū-cạ-lỹp'tī)

Extrait liquide d'Eucalyptus, *Fr.;* Flüssiges Eucalyptusextrakt, *G.*

* "Eucalyptus, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see

page 483), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum, and reserving the first *eight hundred mils* [or 27 fluidounces, 24 minims] of percolate." *U. S.*

This fluidextract well represents the drug, and is of a dark greenish-brown color, having the peculiar odor and taste of eucalyptus very strongly developed, but in effectiveness it is much inferior to the volatile oil.

Dose, from ten to thirty minims (0.6–1.8 mils).

FLUIDEXTRACTUM FRANGULÆ. U. S.

FLUIDEXTRACT OF FRANGULA Fldext. Frangul. [Fluidextract of Buckthorn Bark]

(flū-ĭd-ĕx-trăc'tŭm frăn'gū-læ)

Extrait liquide d'Ecorce de Bourdaine, *Fr.;* **Extractum Frangulæ fluidum,** *P. G.;* **Faulbaum-Fluidextrakt, Flüssiges Faulbaumrindenextrakt,** *G.*

* " Frangula, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]. Prepare a Fluidextract by Type Process D (see page 484). Evaporate the aqueous percolate to *seven hundred and fifty mils* [or 25 fluidounces, 173 minims] and, when cold, add the alcohol and, if necessary, sufficient water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluidextract which has been quite largely used in this country. It is intended to be a laxative, but it is frequently disappointing, as the drug is rarely to be obtained of uniformly good quality. The fluidextract is of a dark reddish-brown color. For a process for Sweet Fluidextract of Buckthorn, see *U. S. D.,* 19th ed., p. 540.

Dose, ten to twenty minims (0.6–1.3 mils).

Off. Prep.—Elixir Catharticum Compositum, *N. F.;* Syrupus Sennæ Compositus, *N. F.*

FLUIDEXTRACTUM GELSEMII. U. S.

FLUIDEXTRACT OF GELSEMIUM Fldext. Gelsem.

(flū-ĭd-ĕx-trăc'tŭm gĕl-sĕm'ĭ-ī)

Extrait liquide de Jasmin jaune ou Gelsemium, *Fr.;* **Flüssiges Gelber Jasminextrakt, Flüssiges Gelsemiumextrakt,** *G.*

* " Gelsemium, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *four volumes* of alcohol and *one volume* of water as the menstruum." *U. S.*

In this fluidextract the former menstruum of alcohol has been replaced in the U. S. P. IX with alcohol, 4 volumes, and water, 1 volume. It is of a dark reddish-brown color.

Dose, from one to three minims (0.06–0.2 mil).

Off. Prep.—Elixir Sodii Salicylatis Compositum, *N. F.*

FLUIDEXTRACTUM GENTIANÆ. U. S.

FLUIDEXTRACT OF GENTIAN Fldext. Gentian.

(flū-ĭd-ĕx-trăc'tŭm jĕn-tī-ā'næ)

Extrait liquide de Gentiane, *Fr.;* **Flüssiges Enzianextrakt,** *G.*

* " Gentian, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using diluted alcohol as the menstruum." *U. S.*

This is a translucent, reddish-brown fluid, with the odor and taste of the root. It may be questionable whether it is needed, though it has the advantage that we may obtain from it the tonic effects of the drug with less alcohol than in an equivalent quantity of the tincture, and pharmaceutically it affords a convenient method of giving to mixtures the tonic properties of gentian when required.

Dose, from ten to thirty minims (0.6–1.8 mils).

Off. Prep.—Elixir Gentianæ, *N. F.;* Elixir Gentianæ et Ferri, *N. F.;* Elixir Gentianæ et Ferri Phosphatis, *N. F.;* Elixir Gentianæ Glycerinatum, *N. F.*

FLUIDEXTRACTUM GLYCYRRHIZÆ. U. S. (Br.)

FLUIDEXTRACT OF GLYCYRRHIZA Fldext. Glycyrrh.

(flū-ĭd-ĕx-trăc'tŭm glĭç-ĭr-rhī'zæ)

Extractum Glycyrrhizæ Liquidum, *Br.;* **Liquid Extract of Liquorice; Fluidextract of Licorice or Liquorice; Extrait liquide de Réglisse,** *Fr.;* **Flüssiges Süssholzwurzelextrakt,** *G.*

* " Glycyrrhiza, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *two hundred and fifty mils* [or 8 fluidounces, 218 minims]; Ammonia Water, Chloroform Water, Water, each, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix *three hundred mils* [or 10 fluidounces, 69 minims] of ammonia water with *twenty-seven hundred mils* [or 91 fluidounces, 142 minims] of chloroform water and moisten the glycyrrhiza with a sufficient quantity of the mixture; pack it in a cylindrical percolator and add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more of the same menstruum until the glycyrrhiza is exhausted. Reserve the first *five hundred mils* [or 16 fluidounces, 435 minims] of the percolate and evaporate the remainder on a water bath to a soft extract; dissolve this in the reserve portion and add enough water to make the product measure *seven hundred and fifty mils* [or 25 fluidounces, 173 minims]. A few drops of ammonia water may be added if necessary to facilitate solution. Now gradually add the alcohol, allow the product to stand for seven days in a stoppered container, then decant the clear liquid, filter the remainder and wash the residue on the filter with enough of a mixture of *one volume* of alcohol and *three volumes* of water to make the Fluidextract measure *one*

thousand mils [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Liquorice Root, in No. 20 powder, 1000 *grammes;* Chloroform Water, 5000 *millilitres;* Alcohol (90 per cent.), *a sufficient quantity.* Mix the Liquorice Root with one-half of the Chloroform Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Chloroform Water, and set aside for six hours; strain; press; mix the strained liquids; heat to 100° C. (212° F.); strain through flannel; evaporate until the liquid has acquired, when cold, a specific gravity of 1.200; add to this one-fourth of its volume of the Alcohol; let the mixture stand for twelve hours; filter." *Br.*

The process for this fluidextract was materially changed in the U. S. P. VIII. The former processes, while making stable fluidextracts of good appearance, were deficient in not providing for the removal of the acrid, oily constituent found in licorice root; the U. S. P. VIII process overcame this difficulty by exhausting the coarsely powdered root with boiling water, concentrating the infusions, adding alcohol to precipitate inert constituents, and filtering; the filtrate was distilled to recover the excess of alcohol, and glycerin, ammonia water and alcohol added to bring the measure to the required standard. This process was essentially that recommended by A. R. L. Dohme. The U. S. P. IX process differs materially. Chloroform water is used to exhaust the licorice root with ammonia water to dissolve the glycyrrhizin, alcohol is added finally to preserve the fluidextract. The object of using chloroform water in the U. S. and British processes is to prevent decomposition in the aqueous liquids. The British formula for the liquid extract has several inconvenient manipulative features, such as the repeated macerations and expressions, evaporating to a certain specific gravity, etc. (See *Mont. Pharm. Journ.*, 1893, 147; *P. J.*, 1898, 188.) This preparation is now very largely used as an adjuvant, and for disguising the bitter taste of quinine, which should be added to the preparation of licorice just before the dose is taken. It is a very convenient form for using licorice, as the ammonia renders the glycyrrhizin soluble, thus materially adding to the power and sweetness of the fluidextract, and it also greatly lessens the acridity. It is a very dark reddish-brown liquid, having the well known sweet taste of licorice, and froths when shaken with water. A *syrup of licorice* may be made by adding two parts of fluidextract to fourteen parts of simple syrup. (See also N. F., Part III.) An elixir containing licorice (*Elixir Adjuvans*) was made official in the U. S. P. VIII and introduced into the U. S. P. IX under the name of *Elixir of Glycyrrhiza.*

Used as a vehicle only.

Off. Prep.—Elixir Glycyrrhizæ, *U. S.;* Mistura Sennæ Composita, *Br.;* Syrupus Sarsaparillæ Compositus, *U. S.;* Elixir Glycyrrhizæ Aquosum, *N. F.;* Elixir Glycyrrhizæ Aromaticum, *N. F.;* Elixir Taraxaci Compositum, *N. F.;* Syrupus Cimicifugæ Compositum, *N. F.*

EXTRACTUM GOSSYPII RADICIS CORTICIS LIQUIDUM. Br.

LIQUID EXTRACT OF COTTON ROOT BARK

(ĕx-trăc'tŭm gŏs-sĭp'ĭ-ī rạd'ĭ-cīs cŏr'tĭ-cīs lĭq'uĭ-dŭm)

"Cotton Root Bark, in No. 30 powder, 1000 *grammes;* Glycerin, 250 *millilitres;* Alcohol (90 per cent.) sufficient to produce 1000 *millilitres.* Mix the Glycerin with seven hundred and fifty *millilitres* of the Alcohol; moisten the Cotton Root Bark with this mixture and continue the *percolation process,* using as menstruum first the remainder of the mixture of Glycerin and Alcohol, and afterwards sufficient of the Alcohol to produce the required volume." *Br.*

The fluidextract of cotton root bark (U. S. P. 1890) was not retained in the U. S. P. VIII or IX, but the National Formulary IV introduced a fluidextract made from the recently-gathered air-dried bark of the root, using alcohol for the menstruum. (See Part III.) The British process requires the use of glycerin which may have a tendency to prevent gelatinization.

Uses.—There is reason to believe that cotton-root bark loses some of its activity in drying. For this reason the preparation of the N. F. IV is to be preferred to the Br. For therapeutic properties of cotton root, see *Gossypii Radicis Cortex.*

Dose, one-half to one fluidrachm (1.8–3.75 mils).

FLUIDEXTRACTUM GRANATI. U. S.

FLUIDEXTRACT OF POMEGRANATE

Fldext. Granat.

(flû-ĭd-ĕx-trăc'tŭm grạ-nā'tī)

Fluidextract of Pomegranate Root Bark; Extrait liquide d'Ecorce de Balaustier, Extrait liquide d'Ecorce de Grenadier, *Fr.;* Flüssiges Granatwurzelrindenextrakt, *G.*

* "Pomegranate, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see page 483), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol and *four hundred mils* [or 13 fluidounces, 252 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." *U. S.*

This fluidextract was admitted to the U. S. Pharmacopœia (8th Revision) for the first time; it well represents the virtues of pomegranate.

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

FLUIDEXTRACTUM GRINDELIÆ. U. S. (Br.)

FLUIDEXTRACT OF GRINDELIA

Fldext. Grindel.

(flû-ĭd-ĕx-trăc'tŭm grĭn-dē'lĭ-æ)

Extractum Grindeliæ Liquidum, *Br.,* Liquid Extract of Grindelia; Extrait liquide de Grindélia, *Fr.;* Flüssiges Grindelienextrakt, *G.*

* "Grindelia, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *three volumes*

of alcohol and *one volume* of water as the menstruum." *U. S.* "Grindelia, in No. 40 powder, 1000 *grammes;* Sodium Bicarbonate, 100 *grammes;* Distilled Water, 500 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Exhaust the Grindelia by *percolation* with the Alcohol. Recover the alcohol from the percolate by distillation, and dissolve the residue in the Distilled Water, to which the Sodium Bicarbonate has previously been added; after effervescence has ceased, add sufficient Distilled Water to produce seven hundred and fifty *millilitres,* and then sufficient of the Alcohol to produce the required volume." *Br.*

This is a fluidextract which well represents the drug; owing to the large quantity of resinous matter present, it does not mix well with aqueous liquids. The so-called "*alkaline fluid extract of grindelia*" may be made by evaporating one pint of official fluidextract until reduced to twelve fluidounces, making a solution of 180 grains of sodium bicarbonate in four fluidounces of water, adding it slowly to the evaporated fluidextract, and filtering; the British liquid extract is made upon this principle. The fluidextract is a dark brown liquid having the peculiar odor of grindelia.

For medical properties and uses, see *Grindelia.*

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

FLUIDEXTRACTUM GUARANÆ. U. S.

FLUIDEXTRACT OF GUARANA Fldext. Guaran.

(flū-ĭd-ĕx-trăc'tŭm guą-rā'næ)

"*One hundred mils* of Fluidextract of Guarana yields not less than 3.6 Gm. nor more than 4.4 Gm. of caffeine." *U. S.*

Extrait liquide de Guarana, *Fr.;* Flüssiges Guaranaextrakt, *G.*

* "Guarana, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum, and reserving the first *eight hundred mils* [or 27 fluidounces, 24 minims] of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloid in the remainder of the liquid and dilute this with enough menstruum to make each *one hundred mils* of the finished Fluidextract contain 4 Gm. of caffeine." *U. S.*

Assay.—Introduce 5 mils of Fluidextract of Guarana into a separator, add 1 mil of ammonia water, and shake out the alkaloid with chloroform until completely extracted, as shown by testing with iodine T.S. Evaporate the combined chloroform solutions to dryness and dissolve the residue in 20 mils of distilled water with the aid of heat. Allow this to cool, filter it into a separator and wash the container and filter with several small portions of distilled water, adding the rinsings to the liquid in the separator. Then shake out the alkaloid with chloroform until completely extracted, as shown by testing with iodine T.S., evaporate the combined chloroform solutions and dry the residue to constant weight at 80° C. (176° F.). The weight represents the alkaloid in 5 mils of Fluidextract of Guarana (see Proximate Assays, Part III)." *U. S.*

The menstruum for this fluidextract, U. S. P. IX (alcohol 3, water 1), is stronger than that of the U. S. P. VIII (diluted alcohol).

This fluidextract is of doubtful utility. The powdered drug itself is portable, not unpleasant to the taste, and is efficient when given suspended in water; nothing is gained by making it into a fluidextract. The fluidextract is of a deep reddish-brown color. (See *Proc. A. Ph. A.,* 1897, 423.)

Dose, one to two fluidrachms (3.75–7.5 mils).

Off. Prep.—Elixir Guaranæ, *N. F.*

EXTRACTUM HAMAMELIDIS LIQUIDUM. Br.

LIQUIDEXTRACT OF HAMAMELIS

(ĕx-trăc'tŭm hăm-ą-mĕl'ĭ-dĭs lĭq'uĭ-dŭm)

Fluidextractum Hamamelis Foliorum, Fluidextract of Hamamelis Leaves; Fluidextract of Witch-hazel Leaves; Extrait liquide de Hamamélis, *Fr.;* Flüssiges Hamamelisextrakt, *G.;* Extracto fluido de hamamelis, *Sp.*

"Hamamelis Leaves, dried, in No. 40 powder, 1000 *grammes;* Alcohol (45 per cent.), sufficient to produce 1000 *millilitres.* Exhaust the Hamamelis Leaves by *percolation* with the Alcohol. Reserve the first eight hundred and fifty *millilitres* of the percolate; recover the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient of the Alcohol to produce the required volume." *Br.*

This liquid extract well represents the virtues of witchhazel. The fluidextract of hamamelis leaves of the U. S. P. VIII was not retained in the U. S. P. IX, but will be found in the N. F. (See Part III.) It has a dark reddish-brown color.

Dose, ten to thirty minims (0.6–1.8 mils).

Off. Prep.—Unguentum Hamamelidis, *Br.*

FLUIDEXTRACTUM HYDRASTIS. U. S. (Br.)

FLUIDEXTRACT OF HYDRASTIS Fldext. Hydrast. [Fluidextract of Golden Seal]

(flū-ĭd-ęx-trăc'tŭm hȳ-drăs'tĭs)

"*One hundred mils* of Fluidextract of Hydrastis yields not less than 1.8 Gm. nor more than 2.2 Gm. of the ether-soluble alkaloids of hydrastis." *U. S.* "Liquid Extract of Hydrastis contains in 100 millilitres 2 grammes of hydrastine." *Br.*

Extractum Hydrastis Liquidum, *Br.;* Liquid Extract of Hydrastis; Extrait liquide de Hydrastis, *Fr.;* Extractum Hydrastis fluidum, *P. G.;* Hydrastis-Fluidextrakt; Flüssiges Hydrastisextrakt, *G.;* Estratto di idraste liquido, *It.;* Extracto fluido de hidrastis, *Sp.*

* "Hydrastis, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see

page 483), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *six hundred mils* [or 20 fluidounces, 138 minims] of alcohol and *two hundred mils* [or 6 fluidounces, 366 minims] of water as Menstruum I, and a mixture of *two volumes* of alcohol and *one volume* of water as Menstruum II. Reserve the first *seven hundred and fifty mils* [or 25 fluidounces, 173 minims] of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough of Menstruum II to make each *one hundred mils* of the finished Fluidextract contain 2 Gm. of the ether-soluble alkaloids of hydrastis.

"Hydrastis Rhizome, in No. 60 powder, 1000 *grammes;* Alcohol (60 per cent.), *a sufficient quantity.* Exhaust the Hydrastis Rhizome with the Alcohol by the *percolation process;* reserve the first eight hundred and fifty *millilitres* of the percolate; recover the alcohol from the remainder by distillation; evaporate to a soft extract and dissolve in the reserved portion.

"**Assay.**—Proceed as directed under *Fluidextractum Belladonnæ Radicis,* page 486), modifying the process there given by using 5 mils of Fluidextract of Hydrastis instead of 10 mils of the fluidextract of belladonna root and using only ether as the immiscible solvent throughout the assay. Dry the residue to constant weight at 100° C. (212° F.), instead of titrating it. The weight represents the amount of ether-soluble alkaloids in 5 mils of the Fluidextract of Hydrastis." *U. S.*

"Determine the proportion of hydrastine in the liquid extract thus obtained by the following process: Transfer 10 millilitres of the liquid extract to a 100 millilitre graduated flask, add 20 millilitres of *solution of potassium iodide* diluted with 60 millilitres of *water,* and then sufficient *water* to produce 100 millilitres. Shake the mixture for several minutes and filter. Transfer 50 millilitres of the filtrate to a separator, render alkaline with *solution of ammonia,* add 30 millilitres of *ether,* and shake at intervals during several minutes. Allow the liquids to separate, draw off the aqueous solution into a beaker and the ethereal solution into a tared beaker. Return the aqueous solution to the separator and repeat the operation with two successive portions, each of 20 millilitres, of *ether* for one minute. Draw off and reject the aqueous layer; transfer the ethereal solutions to the tared beaker and evaporate at a gentle heat; dry the residue on a water-bath and weigh. The weight is that of the hydrastine in 5 millilitres of the liquid extract examined. To the remainder of the liquid extract add sufficient of the menstruum to produce a Liquid Extract of Hydrastis containing 2 grammes of hydrastine in 100 millilitres. Examined by the foregoing process Liquid Extract of Hydrastis is found to contain in 100 millilitres 2 grammes of hydrastine. *Limit of error* 0.1 gramme in excess or defect. This Liquid Extract contains 2 grammes of hydrastine in 100 millilitres; 110 minims contain 2 grains." *Br.*

The fluidextract thoroughly represents the drug. It is of a deep brownish-yellow color.

Dose, from fifteen minims to one fluidrachm (0.9–3.75 mils).

Off. Prep.—Tinctura Hydrastis, *Br.;* Mistura Rhei Alkalina, *N. F.*

FLUIDEXTRACTUM HYOSCYAMI. U. S.

FLUIDEXTRACT OF HYOSCYAMUS Fldext. Hyosc. [Fluidextract of Henbane]

(flū-ĭd-ĕx-trăc'tŭm hȳ-ŏs-cȳ'ă-mī)

"*One hundred mils* of Fluidextract of Hyoscyamus yields not less than 0.055 Gm. nor more than 0.075 Gm. of the alkaloids of hyoscyamus." *U. S.*

Extrait liquide de Jusquiame, *Fr.;* Flüssiges Bilsenkrautextrakt, *G.*

* "Hyoscyamus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough menstruum to make each *one hundred mils* of the finished Fluidextract contain 0.065 Gm. of the alkaloids of hyoscyamus." *U. S.*

"**Assay.**—Proceed as directed under *Fluidextractum Belladonnæ Radicis,* page 486, modifying the process there given by using 25 mils of the Fluidextract of Hyoscyamus in place of 10 mils of fluidextract of belladonna root, and before titrating treating the residue twice with 5 mils of ether and evaporating to dryness each time.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the total alkaloids of hyoscyamus." *U. S.*

The menstruum for this fluidextract was improved in the revision of the U. S. Pharmacopœia IX by increasing the alcoholic strength to alcohol 3, water 1. It is of a very dark greenish-brown color. For the medicinal properties, see *Hyoscyamus.*

Dose, from three to ten minims (0.2–0.6 mil).

FLUIDEXTRACTUM IPECACUANHÆ. U. S. (Br.)

FLUIDEXTRACT OF IPECAC Fldext. Ipecac.

(flū-ĭd-ĕx-trăc'tŭm ĭp-ĕ-căc-ū-ăn'hæ)

"*One hundred mils* of Fluidextract of Ipecac yields not less than 1.8 Gm. nor more than 2.2 Gm. of the ether-soluble alkaloids of ipecac." *U. S.* "Liquid Extract of Ipecacuanha contains in 100 millilitres 2 grammes of the alkaloids of Ipecacuanha Root." *Br.*

Extractum Ipecacuanhæ Liquidum, *Br.;* Liquid Extract of Ipecacuanha; Extrait liquide d'Ipécacuanha, *Fr.;* Flüssiges Ipecacuanhaextrakt, *G.*

* "Ipecac, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see page 483), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of diluted hydrochloric acid, *two hundred mils* [or 6 fluidounces, 366 minims] of alcohol and *two hundred mils* [or 6 fluidounces, 366 minims] of water as Menstruum I, and a mixture of *two volumes* of alcohol and *three volumes* of water as Menstruum II. Reserve the first *eight hundred mils* [or 27 fluidounces, 24 minims] of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough of Menstruum II to make each *one hundred mils* of the finished Fluidextract contain 2 Gm. of the ether-soluble alkaloids of ipecac." *U. S.*

"Ipecacuanha Root, in No. 120 powder, 1000 *grammes;* Alcohol (90 per cent.), *a sufficient quantity.* Pack the Ipecacuanha Root uniformly in a conical percolator, add two hundred *millilitres* of the Alcohol, and set aside for twelve hours; then percolate with successive portions, each of two hundred *millilitres,* of the Alcohol, added at intervals of twelve hours, until the liquid begins to drop from the orifice of the percolator. Continue the percolation with more of the Alcohol until seven hundred and fifty *millilitres* of percolate have been collected. Reserve this portion. Then percolate until exhaustion is complete; recover the alcohol from this percolate by distillation, and dissolve the residual extract in the reserved portion." *Br.*

Assay of Fluidextract of Ipecac.—"From a pipette drop 10 mils of Fluidextract of Ipecac evenly over the surface of 10 Gm. of purified sawdust (see Part III), and evaporate it to dryness at a temperature not exceeding 80° C. (176° F.). Transfer the impregnated sawdust to a 250 mil flask and add 100 mils of ether. Rinse the dish in which the mixture was evaporated with 6 mils of ammonia water, previously diluted with an equal volume of water, used in several portions, and add the rinsings to the flask. Stopper the flask and shake in vigorously every few minutes, during two hours. Now add 15 mils of distilled water, again shake the flask well, and when the sawdust has subsided decant 50 mils of the ether solution, representing 5 mils of the Fluidextract. Completely extract the alkaloids from this solution by shaking out with weak sulphuric acid. Collect the acid washings in a separator; add ammonia water until the solution is decidedly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with ether. Evaporate the combined ether washings to dryness, dissolve the alkaloid from the residue in exactly 10 mils of tenth-normal sulphuric acid V.S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., cochineal T.S. being used as indicator (see Proximate Assays, Part III).

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 24 milligrammes of the ether-soluble alkaloids of ipecac." *U. S.*

"Determine the proportion of alkaloids in the liquid extract thus obtained by the following process: Introduce 5 *millilitres* of the liquid extract into a separator and add 4 *millilitres* of *water,* 1 *millilitre* of *diluted sulphuric acid,* and 10 *millilitres* of *ether.* Shake, and separate the ethereal solution. Repeat the shaking with 5 *millilitres* of *ether* and again separate. Wash the mixed ethereal solutions in a second separator with two successive portions, each of 5 *millilitres,* of *water,* and add the washings to the contents of the first separator. Shake this aqueous liquid with 10 *millilitres* of *chloroform* and excess of *solution of ammonia.* Separate the chloroformic solution and filter it through a small filter-paper into a tared dish. Repeat the shaking with *chloroform,* separation, and filtration, twice, finally washing the filter-paper with a little *chloroform.* Evaporate the mixed chloroformic solutions to about 2 *millilitres,* add 5 *millilitres* of *ether,* evaporate, dry at a temperature not exceeding 80° C. (176° F.) and weigh the residual alkaloids. To the remainder of the liquid extract add sufficient of the Alcohol to produce a Liquid Extract of Ipecacuanha containing in 100 *millilitres* 2 grammes of the alkaloids of Ipecacuanha Root. Examined by the foregoing process Liquid Extract of Ipecacuanha is found to contain in 100 millilitres 2 grammes of the alkaloids of Ipecacuanha Root. *Limit of error* 0.1 gramme in excess or defect. This Liquid Extract contains 2 grammes of the alkaloids of Ipecacuanha Root in 100 millilitres; 110 minims contains 2 grains." *Br.*

The menstruum for the U. S. fluidextract was altered in the U. S. P. IX by the addition of hydrochloric acid, which combines with the alkaloids and more thoroughly exhausts the ipecac. It was proved by J. U. Lloyd that when alcohol alone is used a portion of emetine escapes solution. On the other hand, it is known that when the menstruum is more aqueous large amounts of the pectinous principles are taken up, and it is very desirable to separate these in order to prevent their appearance as a flocculent precipitate in syrup of ipecac; but efficiency is to be sought for as the first desideratum, and hence a menstruum which will extract the activity and make a fluidextract that will not let fall a bulky precipitate of inert matter has been secured; usually this will not mix with syrup without slight precipitation, but the improved official process for syrup of ipecac should effectually separate any precipitate resulting from the presence of apotheme in the fluidextract. The British liquid extract (1914) is standardized; the excellent researches of Paul and Cownley on ipecac, and the assay work of Kremel, Keller, and others, undoubtedly prompted the introduction of the process for the liquid extract. (See *Ipecacuanha.*) It will probably be found, however, that the U. S. menstruum is preferable. An *acetic extract of ipecac* (dry) is used in Great Britain; it has been shown that the heating necessary to dry it is injurious to its emetic properties. (*P. J.,* 1895, 158.)

This fluidextract is a thin, dark reddish-brown, transparent liquid, of a bitterish, slightly acrid taste, but without the nauseous flavor of the root. It is a convenient preparation for adding to expectorant and diaphoretic mixtures, and is used officially in preparing the syrup of ipecac, and other preparations named below.

Dose, as emetic, fifteen to thirty minims (0.9–1.8 mils); as an expectorant, one to two minims (0.06–0.12 mil).

Off. Prep.—Syrupus Ipecacuanhæ, *U. S.;* Tinctura Ipecacuanhæ et Opii, *N. F.;* Vinum Ipecacuanhæ, *Br., N. F.;* Mistura Rhei Composita, *N. F.;* Syrupus Asari Compositus, *N. F.;* Syrupus Cimicifugæ Compositus, *N. F.*

EXTRACTUM KAVÆ LIQUIDUM. Br.

LIQUID EXTRACT OF KAVA

(ĕx-trăc'tŭm kāv'æ lĭq'uĭ-dŭm)

"Kava Rhizome, in No. 20 powder, 1000 *grammes;* Alcohol (90 per cent.), *a sufficient quantity;* Alcohol (45 per cent.), *a sufficient quantity.* Mix the powdered Kava Rhizome with two thousand *millilitres* of the Alcohol (90 per cent.); set aside in a closed vessel for forty-eight hours; transfer to a percolator and percolate slowly, reserving the first seven hundred and fifty *millilitres* of the percolate. Continue the percolation, adding the Alcohol (45 per cent.) until the powder is exhausted; recover most of the alcohol from this percolate by distillation; evaporate the residue at a temperature below 80° C. (176° F.) to a soft extract, and dissolve this in the reserved percolate; add sufficient of the Alcohol (90 per cent.) to produce one thousand *millilitres* of the Liquid Extract." *Br.*

This fluidextract was introduced into the British Pharm. (1914), and is also official in the N. F. IV. (See Part III.) It represents kava and may be given in the *dose* of thirty minims to one fluidrachm (1.8–3.75 mils).

FLUIDEXTRACTUM LOBELIÆ. U. S.

FLUIDEXTRACT OF LOBELIA Fldext. Lobel.

(flû-ĭd-ęx-trăc'tŭm lo-bē'lĭ-æ)

Extrait liquide de Lobélie enflée, *Fr.;* Flüssiges Lobelienkrautextrakt, Flüssiges Lobelienextrakt, *G.*

* "Lobelia, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see page 483), using a mixture of *fifty mils* [or 1 fluidounce, 331 minims] of acetic acid, *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol and *four hundred and fifty mils* [or 15 fluidounces, 104 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." *U. S.*

This fluidextract differs from that of the U. S. P. VIII in that the menstruum is acetic acid 1, alcohol 10, water 9 parts. The acetic menstruum is well adapted for exhausting the drug.

This is a valuable fluidextract. It is of a dark olive color, having the acrid taste of lobelia in a very marked degree.

Dose, as an expectorant, from one to five minims (0.06–0.3 mil); as an emetic, from ten to twenty minims (0.6–1.3 mils).

FLUIDEXTRACTUM NUCIS VOMICÆ. U. S. (Br.)

FLUIDEXTRACT OF NUX VOMICA Fldext. Nuc. Vom.

(flû-ĭd-ęx-trăc'tŭm nū'cĭs vŏm'ĭ-cæ)

"*One hundred mils* of Fluidextract of Nux Vomica yields not less than 2.37 Gm. nor more than 2.63 Gm. of the alkaloids of nux vomica." *U. S.* "Liquid Extract of Nux Vomica contains in 100 millilitres 1.5 grammes of strychnine." *Br.*

Extractum Nucis Vomicæ Liquidum, *Br.;* Liquid Extract of Nux Vomica; Extrait liquide de Noix-Vomique, *Fr.;* Flüssiges Krähenaugen-Extrakt, Brechnussextrakt, Strychnossamenextrakt, *G.*

* "Nux Vomica, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum, and reserving the first *eight hundred mils* [or 27 fluidounces, 24 minims] of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough menstruum to make each *one hundred mils* of the finished Fluidextract contain 2.5 Gm. of the alkaloids of nux vomica.

"Nux Vomica, in No. 20 powder, 1000 *grammes;* Alcohol (70 per cent.), *a sufficient quantity.* Exhaust the Nux Vomica with the Alcohol by the *repercolation process* until five hundred millilitres of percolate have been obtained. Place this percolate in a closed vessel with fifteen grammes of Hard Paraffin and heat to 60° C. (140° F.) for a few minutes, shaking vigorously. Allow the contents of the vessel to cool and the layer of paraffin which will have separated to solidify. Pour off the percolate thus freed from fat; filter." *Br.*

Assay.—"Proceed as directed under *Fluidextractum Belladonnæ Radicis,* page 486, using 10 mils of Fluidextract of Nux Vomica, modifying the process there given by dissolving the alkaloidal residue in 10 mils of tenth-normal sulphuric acid V.S. instead of 5 mils.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 36.42 milligrammes of the alkaloids of nux vomica." *U. S.*

"Determine the proportion of strychnine in it by the following process: Evaporate 10 *millilitres* on a water-bath to a syrupy extract; dissolve the residue in 10 *millilitres* of warm *water* and transfer to a separator, washing the dish with a further 10 *millilitres* of *water.* Add 10 *millilitres* of *chloroform* and a solution of 5 *grammes* of *sodium carbonate* in 25 *millilitres* of *water.* Shake vigorously; set aside and separate the chloroformic solution. Repeat the extraction with *chloroform* twice. Mix the three chloro-

formic solutions, and extract the alkaloids by shaking with three successive portions, each of 10 *millilitres*, of *N/1 solution of sulphuric acid*, transferring the acid solutions to a second separator. Make the acid solutions alkaline with *solution of ammonia*, and again extract the alkaloids by shaking successively with 10, 5, and 5 *millilitres* of *chloroform*, drawing off the chloroformic solutions into a small flask. Remove the chloroform by distillation, dissolve the residue in 15 *millilitres* of *water* containing 3 per cent. by weight of *sulphuric acid*, heat the solution to 50° C. (122° F.), add 3 *millilitres* of a mixture of equal volumes of *nitric acid* and *water*, and set aside for ten minutes. Transfer the solution to a separator, rinsing the flask with a little *water*, make alkaline with *solution of sodium hydroxide*, and extract the alkaloid by shaking successively with 10, 5, and 5 *millilitres* of *chloroform*. Wash the mixed chloroformic solutions in a separator with 5 *millilitres* of *water*, transfer to a tared dish and allow the chloroform to evaporate, adding towards the end 5 *millilitres* of *alcohol* (90 per cent.). Evaporate to dryness, dry the residue at 100° C. (212° F.) and weigh. The weight is the weight in *grammes* of the strychnine contained in 10 *millilitres* of percolate. To the remainder of the percolate add sufficient Alcohol (70 per cent.) to produce a Liquid Extract of Nux Vomica containing in 100 *millilitres* 1.5 *grammes* of strychnine. Examined by the foregoing process Liquid Extract of Nux Vomica is found to contain in 100 *millilitres* 1.5 *grammes* of strychnine. *Limit of error* 0.05 *gramme* in excess or defect. This Liquid Extract contains 1.5 grammes of strychnine in 100 *millilitres;* 110 minims contain 1.5 grains." *Br.*

This fluidextract has been retained principally with the view of giving the pharmacist an accurately adjusted liquid preparation of nux vomica which is more concentrated than the tincture. The process of assay is practically the same as that for the extract. The British assay process is based on that recommended by Dunstan and Short. (*P. J.*, 1884, 623.) The menstruum has been carefully selected so that the alkaloids shall be extracted and as much of the oil left in the residue as possible. In order to make a dry powdered extract it would be necessary to separate the fixed oil before assaying it, and then to make up the weight, if necessary, with sugar of milk or some inert, soluble powder. (See *Extractum Nucis Vomicæ.*) An important advantage, aside from that of securing uniformity and safety, is that the operator need not carry the percolation beyond the point at which it ceases to be profitable (on account of the waste of alcohol), because the extract must be brought to a definite alkaloidal strength. Such an extract can be used with great advantage to make tincture or nux vomica of definite alkaloidal strength.

Dose, one to three minims (0.06–0.2 mil).

Off. Prep.—Tinctura Nucis Vomicæ, *Br.;* Extractum Nucis Vomicæ Siccum, *Br.*

EXTRACTUM PICRORHIZÆ LIQUIDUM. Br.

LIQUID EXTRACT OF PICRORHIZA

(ẹx-trăc'tŭm pĭc-rō-rhīz'æ lĭq'uị-dŭm)

"Picrorhiza, in No. 60 powder, 1000 *grammes;* Alcohol (60 per cent.), sufficient to produce 1000 *millilitres*. Exhaust the Picrorhiza with the Alcohol by the *percolation process*. Reserve the first eight hundred and fifty *millilitres* of the percolate; recover the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient of the Alcohol to produce the required volume." *Br.*

This fluidextract was transferred from the British and Colonial Addendum to the British Pharm. (1914). (See *Picrorhiza.*)

Dose, fifteen to sixty minims (0.9–3.75 mils).

FLUIDEXTRACTUM PILOCARPI. U. S.

FLUIDEXTRACT OF PILOCARPUS Fldext. Pilocarp. [Fluidextract of Jaborandi]

(flū-ịd-ẹx-trăc'tŭm pī-lọ-căr'pī)

"*One hundred mils* of Fluidextract of Pilocarpus yields not less than 0.55 Gm. nor more than 0.65 Gm. of the alkaloids of pilocarpus." *U. S.*

Extractum Jaborandi Liquidum, *Br.*, 1898; Liquid Extract of Jaborandi; Extrait liquide de Jaborandi, *Fr.;* Flüssiges Jaborandiextrakt, *G.*

* "Pilocarpus, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *two volumes* of alcohol and *one volume* of water as the menstruum, and reserving the first *eight hundred mils* [or 27 fluidounces, 24 minims] of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough menstruum to make each *one hundred mils* of the finished Fluidextract contain 0.6 Gm. of the alkaloids of pilocarpus."

"**Assay.**—From a pipette drop 15 mils of Fluidextract of Pilocarpus evenly over the surface of 15 Gm. of purified sawdust (see Part III), and evaporate it to dryness on a water bath. Transfer the mixture to a 250 mil flask, add 150 mils of chloroform, and proceed as directed under *Belladonnæ Radix*, page 222, fifth line of the Assay, beginning with the word 'Stopper,' modifying the process there given by increasing the amount of ammonia water to 6 mils, mixed with 5 mils of distilled water, which is to be used, in divided portions, to rinse the dish in which the mixture was evaporated, the rinsings being added to the mixture in the flask; the 100 mils of chloroform solution must be drawn off from the bottom of the flask.

"Each mil of tenth-normal sulphuric acid V.S. corresponds to 20.815 milligrammes of the alkaloids of pilocarpus." *U. S.*

This fluidextract represents jaborandi leaves

thoroughly. Of the liquid preparations of the drug, the infusion and tincture are both open to objection, the former on account of the bulkiness of the dose, and the latter because of the amount of alcohol it contains. Liquid abstract of jaborandi was deleted from the Br. Pharm. (1914).

Dose, from fifteen minims to half a fluidrachm (0.9–1.8 mils).

FLUIDEXTRACTUM PODOPHYLLI. U. S.

FLUIDEXTRACT OF PODOPHYLLUM Fldext. Podophyll.

(flū-ĭd-ĕx-trăc'tŭm pŏd-ō-phĭl'lī)

Fluidextract of May Apple or Mandrake; Extrait liquide de Podophylle, *Fr.;* Flüssiges Fussblattwurzelextrakt, Flüssiges Podophyllumextrakt, *G.*

* "Podophyllum, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using alcohol as the menstruum." U. S.

The menstruum of the U. S. P. VIII fluidextract which was alcohol 4, water 1, was changed to alcohol in the U. S. P. IX. This is a fluidextract which well represents the root, but is of very little use, since podophyllum is much better administered in other forms.

Dose, from five to fifteen minims (0.3–0.9 mil).

FLUIDEXTRACTUM RHEI. U. S.

FLUIDEXTRACT OF RHUBARB Fldext. Rhei

(flū-ĭd-ĕx-trăc'tŭm rhē'ī)

Extrait liquide de Rhubarbe, *Fr.;* Flüssiges Rhabarberextrakt, *G.*

* "Rhubarb, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *four volumes* of alcohol and *one volume* of water as the menstruum." *U. S.*

The present process affords a fluidextract which thoroughly represents the root, but when mixed with syrups and water, it loses its transparency. An alkali or an alkaline carbonate dissolves this precipitate, but the use of the fluidextract is limited. The British Pharm. (1898) "Liquor Rhei Concentratus" is made with alcohol (20 per cent.) as a menstruum and is one-half the strength of the U. S. fluidextract of rhubarb.

Dose, for an adult, as a purgative, twenty to thirty minims (1.3–1.8 mils); as a laxative, from five to ten minims (0.3–0.6 mil).

Off. Prep.—Syrupus Rhei, *U. S.;* Mistura Rhei Alkalina, *N. F.;* Mistura Rhei Composita, *N. F.;* Syrupus Sennæ Compositus, *N. F.;* Vinum Rhei Compositum, *N. F.*

FLUIDEXTRACTUM ROSÆ. U. S.

FLUIDEXTRACT OF ROSE Fldext. Rosæ

(flū-ĭd-ĕx-trăc'tŭm rō'sæ)

Fluidextract of Red Rose; Extrait liquide de Rose rouge, *Fr.;* Flüssiges Essigrosenblumenblätterextrakt, *G.*

* "Red Rose, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see page 483), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol and *four hundred mils* [or 13 fluidounces, 252 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." *U. S.*

This fluidextract is a useful adjuvant and an excellent astringent. It is of a deep red color, with the agreeable flavor of rose. Wm. C. Alpers prefers repercolation for this fluidextract, stating that even a moderate heat imparts an unpleasant odor to the finished product. (*Proc. A. Ph. A.*, 1897, 425.)

Dose, from one to two fluidrachms (3.75–7.5 mils).

Off. Prep.—Mel Rosæ, *U. S.;* Syrupus Rosæ, *N. F.*

FLUIDEXTRACTUM SABAL. U. S.

FLUIDEXTRACT OF SABAL Fldext. Sabal [Fluidextract of Saw Palmetto]

(flū-ĭd-ĕx-trăc'tŭm sā'bąl)

* "Sabal, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *four volumes* of alcohol and *one volume* of water as the menstruum." *U. S.*

This fluidextract was introduced into the U. S. P. IX. It represents the virtues of saw palmetto berries.

Dose, fifteen minims (0.9 mil).

FLUIDEXTRACTUM SARSAPARILLÆ. U. S.

FLUIDEXTRACT OF SARSAPARILLA Fldext. Sarsap.

(flū-ĭd-ĕx-trăc'tŭm sär-są-pą-rĭl'læ)

Extractum Sarsæ Liquidum., *Br.* 1898; Liquid Extract of Sarsaparilla; Liquor Sarsæ; Extrait liquide de Salsepareille, *Fr.;* Flüssiges Sarsaparillaextrakt, *G.*

* "Sarsaparilla, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using diluted alcohol as the menstruum." *U. S.*

The British Pharm. (1914) deleted Extractum Sarsæ Liquidum. The process will be found in the 19th ed., U. S. Dispensatory, page 559.

The introduction of a simple fluidextract of sarsaparilla into our Pharmacopœias was judicious, as it enables the physician to associate this medicine with others at his pleasure, and in such proportions as he may deem expedient. He may rely upon the efficiency of the preparation, if made with sufficient care and skill and from good parcels of the root. The U. S. fluidextract is a somewhat dense, scarcely translucent liquid, of a very dark reddish-brown color, and of a sweetish and a slightly acrid taste.

Dose, thirty to sixty minims (1.8–3.75 mils).

Off. Prep.—Syrupus Sarsaparillæ Compositus, *U. S.*

FLUIDEXTRACTUM SARSAPARILLÆ COMPOSITUM. U. S.

COMPOUND FLUIDEXTRACT OF SARSAPARILLA Fldext. Sarsap. Co.

(flū-ĭd-ĕx-trăc'tŭm săr-să-pă-rĭl'læ cŏm-pŏs'ĭ-tŭm)

Extrait liquide de Salsepareille composé, *Fr.;* Zusammengesetztes flüssiges Sarsaparillaextrakt, *G.*

* "Sarsaparilla, in No. 20 powder, *seven hundred and fifty grammes* [or 26 ounces av., 199 grains]; Glycyrrhiza, in No. 20 powder, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Sassafras, in No. 30 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Mezereum, in No. 30 powder, *thirty grammes* [or 1 ounce av., 25 grains]. Mix the powders and prepare a Fluidextract by Type Process B (see page 483), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *five hundred mils* [or 16 fluidounces, , 435 minims] of alcohol and *four hundred mils* [or 13 fluidounces, 252 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." *U. S.*

The compound fluidextract is intended to represent, in a concentrated state, the compound decoction of sarsaparilla, having all its ingredients with the exception of the guaiacum wood, which probably adds little to the efficacy of the decoction. It was originally proposed by Wm. Hodgson, Jr. (*A. J. P.*, ii, 285), and the official process differs from his mainly in the omission of the guaiacum wood, the resin of which, separating during the evaporation, somewhat embarrassed the process, without adding to the virtues of the extract. The British Pharm. (1898) "Liquor Sarsæ Compositus Concentratus" is of the same strength as the fluidextract of the U. S. Pharmacopœia, and is made with a menstruum of distilled water with 225 mils of alcohol as a preservative in 1000 mils of finished solution.

Dose, from thirty minims to one fluidrachm (1.8–3.75 mils).

FLUIDEXTRACTUM SCILLÆ. U. S.

FLUIDEXTRACT OF SQUILL Fldext. Scill.

(flū-ĭd-ĕx-trăc'tŭm sçĭl'læ)

"If assayed biologically the minimum lethal dose should not be greater than 0.0006 mil of Fluidextract, or the equivalent in Fluidextract of 0.0000005 Gm. of ouabain, for each gramme of body weight of frog." *U. S.*

Extrait liquide de Scille, *Fr.;* Flüssiges Meerzwiebelextrakt, *G.*

* "Squill, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, Alcohol, Water, each, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix *two thousand mils* [or 67 fluidounces, 301 minims] of alcohol with *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of water, moisten the squill thoroughly with sufficient of the mixture and allow it to macerate for two hours in a tightly-covered container. Then transfer it to a percolator, shake it down evenly without packing, and pour on enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more menstruum composed of *two volumes* of alcohol and *one volume* of water. When the percolate measures *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] close the lower orifice and macerate the drug twelve hours before continuing the percolation. Then collect a second *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of percolate, again interrupt the percolation, macerate for twelve hours and then continue the percolation until the total percolate measures *five thousand mils* [or 169 fluidounces, 33 minims]. Recover the alcohol from the percolate at as low a temperature as possible and then concentrate the residue to a volume measuring *eight hundred mils* [or 27 fluidounces, 24 minims]. When the residue is cold, add slowly, with continuous agitation, *two thousand mils* [or 67 fluidounces, 301 minims] of alcohol and set the mixture aside in a tightly-stoppered container for twelve hours. Decant the supernatant liquid from the syrupy layer, filter the decanted liquid and wash the syrupy residue with two portions of *three hundred mils* [or 10 fluidounces, 69 minims] each of a mixture of *four volumes* of alcohol and *one volume* of water, passing the washings through the filter into the previously collected alcoholic liquid. Reduce the combined alcoholic liquids to *eight hundred mils* [or 27 fluidounces, 24 minims] by distillation and finally add enough diluted alcohol to make the finished Fluidextract measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"**Assay.**—For a method of assaying Fluidextract of Squill, see *Digitalis,* and also Biological Assays (Part III)." *U. S.*

The U. S. P. has very properly returned to an alcoholic instead of an acetic acid menstruum for this preparation, as Houghton has shown that the fluidextract of the U. S. P. VIII did not represent the activity of squills, but it is doubtful whether the complicated process of the U. S. P. IX will be employed for such a rarely used fluidextract.

Dose, from one to three minims (0.06–0.2 mil).

Off. Prep.—Syrupus Scillæ Compositus, *U. S.;* Mistura Pectoralis, Stokes, *N. F.*

FLUIDEXTRACTUM SENEGÆ. U. S.

FLUIDEXTRACT OF SENEGA Fldext. Seneg.

(flū-ĭd-ĕx-trăc'tŭm sĕn'ę-gæ)

Extrait liquide de Polygale de Virginie, Extrait liquide de Sénéca, *Fr.;* Flüssiges Senegaextrakt, G.

* "Senega, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Ammonia Water, Alcohol, Water, each, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix *two thousand mils* [or 67 fluidounces, 301 minims] of alcohol

with *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of water, and, having moistened the powder with sufficient of this mixture, pack it in a cylindrical percolator and add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, composed of a mixture of *two volumes* of alcohol and *one volume* of water, until the drug is exhausted. Reserve the first *eight hundred mils* [or 27 fluidounces, 24 minims] of the percolate and evaporate the remainder to a soft extract; dissolve this in the reserved liquid and then gradually add ammonia water until the product is faintly alkaline and possesses a slight odor of ammonia. Finally add enough of the menstruum to make the Fluidextract measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

Formerly, Fluidextract of Senega was very frequently the cause of annoyance to the pharmacist through gelatinization. This was due to the presence of pectinous bodies in the root. The addition of an alkali to the menstruum effectually prevents this, and in this respect the present preparation is a great improvement over the 1890 fluidextract. We prefer, however, solution of sodium hydroxide, as the alkaline liquid, to ammonia water, as the latter is rarely uniform in quality as found in commerce. This fluidextract is a blackish-brown, moderately thin liquid. For other processes, see *N. R.*, 1883, pp. 195, 196. The British Pharm. (1898) "Liquor Senegæ Concentratus" was made half the strength of the U. S. fluidextract with a menstruum composed of 2 parts of 20 per cent. alcohol and 1 part of 45 per cent. alcohol.

Dose, five to twenty minims (0.3–1.3 mils).

Off. Prep.—Syrupus Scillæ Compositus, *U. S.;* Syrupus Senegæ, *U. S.;* Mistura Pectoralis, Stokes, *N. F.;* Syrupus Cimicifugæ Compositus, *N. F.*

FLUIDEXTRACTUM SENNÆ. U. S.

FLUIDEXTRACT OF SENNA Fldext. Senn.

(flū-ĭd-ĕx-trăc'tŭm sĕn'næ)

Extrait liquide de Séné, *Fr.;* Flüssiges Sennaextrakt, *G.*

* "Alexandria Senna, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *one volume* of alcohol and *two volumes* of water as the menstruum, and reserving the first *eight hundred mils* [or 27 fluidounces, 24 minims] of percolate." *U. S.*

The U. S. P. VIII process provided for the elimination of the griping principles by the previous percolation of the powdered senna with alcohol; diluted alcohol was then used to exhaust the drug of the purgative principles. This previous treatment of the senna was deleted from the U. S. P. IX process and the menstruum was made less alcoholic. The fluidextract is a dark, blackish, thick, and somewhat turbid liquid, with a strong flavor of senna. It is well adapted for exhibition with saline cathartics, such as Epsom salt or cream of tartar, which also obviate its griping. In this case not more than one-half of the full dose of the fluidextract should be given at once.

The British Pharm. (1898) "Liquor Sennæ Concentratus" was more like a concentrated infusion than a fluidextract, but had the same strength of the latter, the menstruum is distilled water; tincture of ginger and alcohol being added.

Dose, from one-half to two fluidrachms (1.8–7.5 mils), for an adult.

Off. Prep.—Syrupus Sarsaparillæ Compositus, *U. S.;* Syrupus Sennæ, *U. S.;* Elixir Cascaræ Compositum, *N. F.;* Elixir Catharticum Compositum, *N. F.;* Syrupus Ficorum Compositus, *N. F.;* Syrupus Sennæ Aromaticus, *N. F.;* Syrupus Sennæ Compositus, *N. F.*

FLUIDEXTRACTUM SPIGELIÆ. U. S.

FLUIDEXTRACT OF SPIGELIA Fldext. Spigel. [Fluidextract of Pink Root]

(flū-ĭd-ĕx-trăc'tŭm spĭ-gē'lĭ-æ)

Extrait liquide de Spigélie, *Fr.;* Flüssiges Spigelienextrakt, *G.*

* "Spigelia, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using diluted alcohol as the menstruum." *U. S.*

This preparation differs from that official prior to 1890 in having no glycerin in the menstruum; the U. S. P., 1870, fluidextract contained 50 per cent. of glycerin. Diluted alcohol is an excellent menstruum.

The fluidextract of spigelia is a dark-brown translucent liquid, with the flavor of the root. The dose may be repeated morning and evening for three or four days, and then followed by a brisk cathartic. It is, however, most used in connection with the fluidextract of senna, the fluidextract of spigelia and senna formerly official being an excellent combination, which should not have been dropped from the Pharmacopœia. The formula is as follows:

Extractum Spigeliæ et Sennæ Fluidum, U. S. 1870. *Fluid Extract of Spigelia and Senna.*—"Take of Fluid Extract of Spigelia *ten fluidounces;* Fluid Extract of Senna, *six fluidounces;* Oil of Anise, Oil of Caraway, each, *twenty minims.* Mix the Fluid Extracts, and dissolve the Oils in the mixture." *U. S.* 1870.

Dose, for an adult, from one to two fluidrachms (3.75–7.5 mils); for a child of two or three years, from ten to twenty minims (0.6–1.3 mils).

FLUIDEXTRACTUM STAPHISAGRIÆ. U. S.

FLUIDEXTRACT OF STAPHISAGRIA Fldext. Staphisag. [Fluidextract of Stavesacre]

(flū-ĭd-ĕx-trăc'tŭm stăph-ĭ-sā'grĭ-æ)

Fluidextract of Stavesacre Seed; Extrait liquide des Semences de Staphisaigre, *Fr.;* Flüssiges Stephanskörnerextrakt, *G.*

* " Staphisagria, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using alcohol as the menstruum. The oil which separates in the freshly prepared Fluidextract may be removed by chilling and filtering the cold Fluidextract through a filter moistened with alcohol." *U. S.*

This fluidextract was first made official in the U. S. P. VIII. Mixed with two or three parts of alcohol and ether, it is used as an external application to destroy lice.

FLUIDEXTRACTUM STILLINGIÆ. U. S.

FLUIDEXTRACT OF STILLINGIA Fldext. Stilling.

(flū-id-ĕx-trăc'tŭm stĭl-lĭn'jĭ-æ)

Extrait liquide de Stillingie, *Fr.;* **Flüssiges Stillingiaextrakt,** *G.*

* " Stillingia, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using diluted alcohol as the menstruum." *U. S.*

The glycerin in the menstruum has been abandoned in this fluidextract, which is of a dark reddish-brown color.

Dose, from fifteen to forty-five minims (0.9–2.8 mils).

Off. Prep.—Elixir Corydalis Compositum, *N. F.*

FLUIDEXTRACTUM SUMBUL. U. S.

FLUIDEXTRACT OF SUMBUL Fldext. Sumbul [Fluidextract of Musk Root]

(flū-id-ĕx-trăc'tŭm sŭm'bŭl)

Extrait liquide de Sumbul, *Fr.;* **Flüssiges Sumbulwurzelextrakt oder Moschuswurzelextrakt,** *G.*

* " Sumbul, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *four volumes* of alcohol and *one volume* of water as the menstruum." *U. S.*

This fluidextract was made official for the first time in the U. S. P. VIII, superseding the tincture of sumbul, to which it is superior.

Dose, half a fluidrachm to one fluidrachm (1.8–3.75 mils).

FLUIDEXTRACTUM TARAXACI. U. S.

FLUIDEXTRACT OF TARAXACUM Fldext. Tarax. [Fluidextract of Dandelion]

(flū-id-ĕx-trăc'tŭm tą-răx'ą-cī)

Extractum Taraxaci Liquidum, *Br.* 1898; **Liquid Extract of Taraxacum; Fluidextract of Dandelion; Extrait liquide de Pissenlit,** *Fr.;* **Flüssiges Löwenzahnwurzelextrakt,** *G.*

* " Taraxacum, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see page 483), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *five hundred mils* [or 16 fluidounces, 435 minims] of alcohol and *four hundred mils* [or 13 fluidounces, 252 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." *U. S.*

The activity depends more upon the proper selection of the root than upon anything else. The addition of solution of sodium hydroxide to the menstruum in the U. S. P. VIII revision was dropped in the U. S. P. IX. The process of exhausting the drug is not difficult, and one of the best tests of this fluidextract is its bitter taste. It is a blackish, moderately thick liquid.

Dose, from one to three fluidrachms (3.75–11.25 mils).

Off. Prep.—Elixir Gentianæ Glycerinatum, *N. F.;* Elixir Taraxaci Compositum, *N. F.*

FLUIDEXTRACTUM TRITICI. U. S. (Br.)

FLUIDEXTRACT OF TRITICUM Fldext. Tritic. [Fluidextract of Couch Grass]

(flū-id-ĕx-trăc'tŭm trĭt'ĭ-cī)

Extractum Agropyri Liquidum, *Br.;* **Liquid Extract of Couch Grass; Liquid Extract of Triticum; Fluidextract of Couch-grass Root; Extrait liquide de petit Chiendent,** *Fr.;* **Flüssiges Queckenwurzelextrakt,** *G.*

* " Triticum, finely cut, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *two hundred mils* [or 6 fluidounces, 366 minims], Prepare a Fluidextract by Type Process D (see page 484), evaporate the aqueous percolate to *eight hundred mils* [or 27 fluidounces, 24 minims] and when cold add the alcohol and, if necessary, sufficient water to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

" Couch Grass, cut small, 1000 *grammes;* Distilled Water, boiling, 10,000 *millilitres;* Alcohol (90 per cent.), sufficient to produce 1000 *millilitres.* Boil the Couch Grass with the Distilled Water for thirty minutes; strain; evaporate to seven hundred and fifty *millilitres;* cool, and add sufficient of the Alcohol to produce the required volume; filter." *Br.*

For therapeutic uses, see *Triticum* and *Agropyrum.*

In making this fluidextract in warm weather, it is advisable to commence evaporating the percolate before the drug is exhausted, or fermentation may set in; triticum contains fermentable sugars, and diluted aqueous solutions do not keep well.

This fluidextract represents whatever virtues triticum possesses. The German Pharmacopœia formerly directed an *Extractum Graminis,* by digesting 1 part of Triticum with 6 parts of hot water, for six hours, straining, evaporating to a syrup, mixing 1 part of this extract with 4 parts of cold distilled water, filtering, and evaporating to an extract. The fluidextract is preferable, as the excessive use of heat is avoided.

Dose, from three to six fluidrachms (11.25–22.5 mils).

FLUIDEXTRACTUM UVÆ URSI. U. S.

FLUIDEXTRACT OF UVA URSI Fldext. Uvæ Ursi

(flū-id-ĕx-trăc'tŭm ū'væ ûr'sī)

Extrait liquide de Busserole, *Fr.;* **Flüssiges Bärentraubenblätterextrakt,** *G.*

* " Uva Ursi, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B (see

page 483), using a mixture of *one hundred mils* [or 3 fluidounces, 183 minims] of glycerin, *three hundred mils* [or 10 fluidounces, 69 minims] of alcohol and *five hundred mils* [or 16 fluidounces, 435 minims] of water as Menstruum I, and a mixture of *one volume* of alcohol and *two volumes* of water as Menstruum II. Reserve the first *eight hundred mils* [or 27 fluidounces, 24 minims] of percolate." *U. S.*

This preparation is a dense, black liquid, of a sweet, bitterish, astringent, but not very disagreeable taste.

Dose, from thirty minims to a fluidrachm (1.8–3.75 mils).

FLUIDEXTRACTUM VERATRI VIRIDIS. U. S.

FLUIDEXTRACT OF VERATRUM VIRIDE Fldext. Verat. Vir. [Fluidextract of Green Hellebore]

(flū-ĭd-ĕx-trăc'tŭm vē-rā'trī vĭr'ĭ-dīs)

Fluidextract of American Hellebore; Extrait liquide de Vératre américain, *Fr.;* Flüssiges Grüngermerextrakt, *G.*

* "Veratrum Viride, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using alcohol as the menstruum." *U. S.*

This is the best preparation of veratrum and thoroughly represents the drug.

Dose, one to four minims (0.06–0.24 mil).

FLUIDEXTRACTUM VIBURNI PRUNIFOLII. U. S. (Br.)

FLUIDEXTRACT OF VIBURNUM PRUNIFOLIUM Fldext. Viburn. Prun. [Fluidextract of Black Haw]

(flū-ĭd-ĕx-trăc'tŭm vī-bŭr'nī prū-nĭ-fō'lĭ-ī)

Extractum Viburni Liquidum, *Br.;* Liquid Extract of Black Haw; Extrait liquide de Viburne, *Fr.;* Flüssiges Viburnumextrakt, *G.*

* "Viburnum Prunifolium, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *two volumes* of alcohol and *one volume* of water as the menstruum." *U. S.*

"Black Haw, in No. 60 powder, 1000 *grammes;* Alcohol (70 per cent.), sufficient to produce 1000 *millilitres.* Exhaust the Black Haw with the Alcohol by the *percolation process.* Reserve the first eight hundred and fifty *millilitres* of the percolate; recover the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient of the Alcohol to produce the required volume." *Br.*

This is a fluidextract which well represents the drug. It is of a dark reddish-brown color.

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

Off. Prep.—Elixir Viburni Prunifolii, *N. F.*

FLUIDEXTRACTUM XANTHOXYLI. U. S.

FLUIDEXTRACT OF XANTHOXYLUM Fldext. Xanthox. [Fluidextract of Prickly Ash]

(flū-ĭd-ĕx-trăc'tŭm xăn-thŏx'ȳ-lī)

Extrait liquide d'Ecorce de Clavalier, *Fr.;* Flüssiges Zahnwehrindenextrakt, *G.*

* "Xanthoxylum, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of *three volumes* of alcohol and *one volume* of water as the menstruum." *U. S.*

This fluidextract thoroughly represents the virtues of the drug. (See *Xanthoxylum.*)

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

Off. Prep.—Elixir Corydalis Compositum, *N. F.*

FLUIDEXTRACTUM ZINGIBERIS. U. S.

FLUIDEXTRACT OF GINGER Fldext. Zingib.

(flū-ĭd-ĕx-trăc'tŭm zĭn-gĭb'ĕ-rĭs)

Extrait liquide de Gingembre, *Fr.;* Flüssiges Ingwerextrakt, *G.*

* "Jamaica Ginger, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using alcohol as the menstruum." *U. S.*

This fluidextract is a highly concentrated alcoholic solution of the active principles of ginger. It is transparent, and of a reddish color.

Dose, from five to twenty minims (0.3–1.3 mils).

Off Prep.—Syrupus Zingiberis, *U. S.*

FŒNICULUM. U. S. (Br.)

FENNEL Fœnic. [Fennel Seed]

(fœ-nĭc'ū-lŭm)

"The dried, ripe fruit of cultivated varieties of *Fœniculum vulgare* Miller (Fam. *Umbelliferæ*), without the presence or admixture of more than 4 per cent. of foreign matter." *U. S.* "Fennel Fruit is the ripe fruit of Fœniculum vulgare, *Mill.,* collected from cultivated plants, and dried." *Br.*

Fœniculi Fructus, *Br.;* Semen Fœniculi, Fennel Fruit (Seed), Sweet Fennel Fruit; Fenouil doux (Fruit), *Fr. Cod.;* Fruits (Semences) de Fenouil, *Fr.;* Fructus Fœniculi, *P. G.;* Fenchel, Fenchelsamen, *G.;* Finocchio, *It.;* Hinojo, *Sp.*

The plant producing fennel seed was attached by Linnæus to the genus *Anethum,* but was separated from it by De Candolle, and placed, with three or four others, in a new genus styled *Fœniculum,* which has been generally adopted by botanists. The *Anethum Fœniculum* of Linnæus embraced two varieties, the *common* or *wild fennel,* and the *sweet fennel,* the latter being the plant usually cultivated in the gardens of Europe. These are considered by De Candolle as distinct species, and named respectively *Fœniculum vulgare* and *Fœniculum dulce,* but the correctness of the opinion of the great Swedish botanist is now generally admitted.

Fœniculum vulgare is a stout, glabrous biennial or perennial, aromatic herb, with leaves dissected into numerous filiform segments. The flowers are in large, flat, terminal umbels, with from thirteen to twenty rays, and destitute both of general and partial involucres. The

corolla consists of five petals, which, as well as the stamens, are golden yellow. The fruit is ovate, and of a dark color, especially in the grooves. The plant is a native of Europe, growing wild upon sandy and chalky ground throughout the continent, and is also abundant in Asia, possibly extending as far as China. It is extensively cultivated in Europe as well as in this country. It has escaped from gardens and is somewhat naturalized in Maryland and Virginia. In India fennel is said to be obtained from *F. panmorium* DC., which is probably, however, only a variety of the official plant. Sicilian fennel is affirmed to be the fruit of *F. piperitum.*

F. dulce De Cand., *Sweet Fennel* bears a general resemblance to *F. vulgare,* but differs in having its stem somewhat compressed at the base, its radical leaves somewhat distichous, and the number of rays in the umbel only from 6 to 8. It is also a much smaller plant, being only about a foot high; its flowers appear earlier, and its young sweet shoots or turiones are eaten in Italy boiled or as a salad. According to Index Kewensis it is identical with *F. vulgare.*

Properties.—The roots of fennel were formerly employed in medicine, but are generally inferior in virtues to the fruit, which is now the only portion recognized by any of the pharmacopœias. It is stated that manufacturers of the oil usually distil the whole plant.

The official description is as follows: "Mericarps usually separate, each being broadly elliptical, more or less curved, from 4 to 10 mm. in length and from 1 to 3.5 mm. in breadth, some having a slender stalk from 2 to 10 mm. in length; dorsal surface convex, yellowish-green to grayish-brown, with three prominent, longitudinal primary ribs and at the summit a short, conical stylopodium; commissural surface with three narrow, light brown, longitudinal areas separated by two dark brown or brownish-black areas containing the vittæ or oil-tubes; odor and taste aromatic and characteristic. Under the microscope, transverse sections of Fennel show a pentagonal mericarp, four of the edges being nearly equal and slightly concave, the other or commissural surface being much longer and more or less undulate; cells of the seed-coat closely united with those of the pericarp, giving the section two very distinct areas, the inner and larger portion (endosperm) more or less rounded-pentagonal and somewhat reniform, composed of polygonal cells, filled with aleurone grains containing rosette aggregates of calcium oxalate and a thin protoplasmic layer enclosing a fixed oil; the outer or pericarp layer distinguished by large elliptical vittæ with thick, brown walls, occurring singly and alternating with the primary ribs, and two vittæ on the dorsal surface, making usually six vittæ in all, there sometimes being, however, one or two vittæ additional; in the central portion of each of the ribs occurs a nearly circular, fibro-vascular bundle with a few tracheæ and numerous thin-walled, strongly lignified sclerenchymatous fibers. The powder is yellowish-brown consisting of irregular angular fragments; tissues of endosperm, colorless, the cells filled with aleurone grains, each containing a rosette aggregate of calcium oxalate, about 0.002 mm. in diameter; fragments containing yellowish-brown vittæ, from 0.1 to 0.2 mm. in width; sclerenchymatous fibers few, strongly lignified and with numerous, oblique, simple pores; parenchyma cells with more or less thick walls and simple pores and occasionally reticulately thickened; tracheæ few and either spiral or annular; in mounts made with hydrated chloral T.S., numerous globules of a fixed oil separate. Fennel yields not more than 9 per cent. of ash." *U. S.*

Fennel seeds (half fruits) are officially described in the Br. Pharm. as follows:

"Small, oblong, straight or slightly curved, from three to ten millimetres long, and from two to four millimetres in diameter. Greenish or greenish-brown. Each of the two mericarps with five prominent principal ridges and six large vittæ. Aromatic odor; taste strong, sweet and camphoraceous. Ash not more than 11 per cent." *Br.*

There are ten chief varieties of fennel known in commerce, the fruits differing very much in size and considerably in taste. They are as follows: French (sweet); French (bitter); German; Puglis; Indian; Russian; Macedonian; Galician; Persian and Japanese. For histological differences of the different commercial varieties see monograph by Hartwich and Jama in *B. P. G.,* 1909, p. 306. Rosenthaler (*B. P. G.,* 1913, p. 570) has made a pharmacognostical study of a Chinese fennel.

Commercial fennel varies greatly in quality, this being either due to lack of care in harvesting or deliberate adulteration. It may contain sufficient sand, dirt, stem tissues, weed seeds, or other material beyond the 4 per cent. limit prescribed by the Pharmacopœia that it amounts to adulteration. The fruits, especially the powder, may be deficient in volatile oil, inferring that they have been partly exhausted. Exhausted or otherwise inferior fennel is occasionally improved in appearance by the use of a factitious coloring. (See Spaeth, in *Ph. Zentralh.,* 1908, p. 545; and 1913, p. 736.)

Schimmel & Co.'s Semi-Annual Report for April, 1897, gives as additional varieties of fennel—Aleppo, oil amounting to 0.75 per cent.; Macedonian, 3.4 to 3.8 per cent.; Moravian, 3 per cent.; Milanese, 4.2 per cent.; Roumanian, 4.6 per cent.; Spanish, amount not stated; and Syrian (Damascus), 1.6 per cent. Of these, the Syrian may be the same as that called Persian by Umney, and the Roumanian the same as that called Russian. Several additional varieties are also mentioned by Umney (*P. J.,* 1897, lviii, p. 226), who states that the European varieties were almost entirely displaced by the East Indian seed and that the latter would probably be supplanted by the Japanese variety.

The odor of fennel seed is fragrant, its taste warm, sweet, and agreeably aromatic. It yields its virtues to hot water, but more freely to

alcohol. The essential oil may be separated by distillation with water. (See *Oleum Fœniculi.*) From 960 parts of the seed Neumann obtained 20 parts of volatile and 120 of fixed oil.

Uses.—Fennel seed was used by the ancients. It is one of our most grateful aromatics, and in this country is much employed as a carminative, and as a corrigent of other less pleasant medicine, particularly senna and rhubarb. It is recommended for these purposes by the absence of any highly excitant property. An infusion may be prepared by introducing two or three drachms of the seeds into a pint of boiling water. In infants the infusion is frequently employed as an enema for the expulsion of flatus.

Dose, of the bruised or powdered seeds, twenty grains to half a drachm (1.3–2.0 Gm.).

F.;* Species Laxativæ, *N. F.;* Tinctura Antiperiodica, *N. F.;* Tinctura Antiperiodica sine Aloe, *N. F.*

FRANGULA. U. S.

FRANGULA Frang. [Buckthorn Bark]

(frăn'gū-lą)

"The dried bark of *Rhamnus Frangula* Linné (Fam. *Rhamnaceæ*)." *U. S.*

Rhamni Frangulæ Cortex, *Br.* (1885); Frangula Bark; Alder Buckthorn; Ecorce de Bourdaine, Bourgène, *Fr.;* Cortex Frangulæ, *P. G.;* Faulbaumrinde, *G.;* Corteccia di frangola, *It.*

R. Frangula or *Alder Buckthorn* is an erect glabrous shrub from ten to fifteen feet high, without thorns, with broadly ovate obtuse leaves, the margins being entire or slightly sinuate, the under side sometimes slightly downy, and the rather numerous lateral veins diverging equally almost from the whole length of the midrib. Flowers all hermaphrodite, two or three together in each axil, with the calyx teeth, petals, and stamens in fives. Fruit dark purple, the size of a pea. This plant grows in hedges and bushy places throughout Europe and Russian Asia, except in the far north. It has become established on Long Island, northern New Jersey and in Ontario.

It is probable that most of the species of the genus *Rhamnus* have cathartic properties. An article upon *R. Purshiana* will be found elsewhere, as it is official in both of the Pharmacopœias. (See *Cascara Sagrada.*) The *R. catharticus* Linn., or common buckthorn, grows in Europe along with the official species, and has become locally naturalized in the Eastern portions of the United States. Its bark is probably often sold for the official article. It is distinguished by its more spreading, thorny habit, and its diœcious flowers, which are thickly clustered in the axils and have their parts in fours. The leaves also are more acute, have their margins finely serrate and their lateral veins mostly proceeding from the proximal half of the midrib. The fruit is purplish-black.

Properties.—This bark is officially described as "in quills varying in length, frequently flattened or crushed; from 0.5 to 1 mm. in thickness; outer surface grayish-brown or purplish-black, with numerous, prominent, lighter-colored, transverse lenticels and occasional patches of foliaceous lichens bearing small, blackish apothecia; inner surface smooth, dark brown with occasional purplish blotches, longitudinally striate, becoming red when moistened with solutions of the alkalies; fracture short, slightly fibrous in the inner layer; odor distinctive; taste slightly bitter. Under the microscope, transverse sections of Frangula show a distinctly undulate corky layer, composed of about 12 rows of reddish-brown cells; parenchyma cells of the primary cortex with numerous rosette aggregates of calcium oxalate, from 0.01 to 0.025 mm. in diameter; inner bark with bast-fibers in narrow, interrupted rows, the groups of fibers being separated radially by the medullary rays; bast-fibers with thick, strongly lignified, yellowish walls and narrow lumina and each group surrounded by a layer of crystal fibers, the prismatic crystals of calcium oxalate varying from 0.007 to 0.015 mm. in diameter, medullary rays one to two cells in width, occasionally three; cells of the parenchyma and medullary rays with numerous starch grains, 0.003 mm. in diameter. The powder is yellowish-brown; stone cells absent (distinguishing it from the powder of *Cascara Sagrada*). Add 0.1 Gm. of powdered Frangula to 10 mils of hot distilled water, shake the mixture occasionally until cold and filter; on the addition of a few drops of ammonia water, the filtrate is colored a deep red. Macerate 0.1 Gm. of powdered Frangula with 10 drops of alcohol, boil with 10 mils of distilled water and filter when cold. Shake this filtrate with 10 mils of ether; a yellow, ethereal solution separates, and 3 mils of this ethereal solution, when shaken with 3 mils of ammonia water, yields an alkaline solution, which, on being diluted with 20 mils of distilled water, still possesses a distinct cherry-red color. Frangula yields not more than 6 per cent. of ash." *U. S.*

As first pointed out by Schrenk (*Am. Drug.,* April, 1887), the bark of *Rhamnus Frangula* can be distinguished from that of *R. Purshiana* (*Cascara Sagrada*) by the absence of the irregular angular sclerenchymatous cells, which in *R. Purshiana* are wedged together in large compact groups, increasing in size and number towards the surface, and causing the short fracture of the outer bark.

Tschirch and Pool (*S. W. P.,* 1908, p. 665) have made a comparative pharmacognostical and chemical study of the barks of *R. Frangula* and *R. Purshiana.* Würffel (*Zeit. Oest. Apoth. Ver.,* 1907, p. 211) and Mitlacher (*Bull. sc. pharmacol.,* 1911, p. 10) report the substitution of Frangula by the bark of an alder (*Alnus glutinosa* Medic). The latter may be detected by not being reddened with solutions of the alkalies. Mitlacher (*Ph. Post,* 1905, p. 751) and

Moser (*A. J. P.*, 1909, p. 580) have found that the official Frangula is either admixed with or entirely substituted by the bark of *R. carniolica* A. Kerw. E'we (*Proc. A. Ph. A.*, 1914, p. 131) obtained a sample of Frangula which proved to be wild-cherry bark.

It is not certainly known which of the several bodies isolated from frangula bark is the purgative principle. The most important body, *frangulin*, the *rhamnoxanthin* ($C_{20}H_{20}O_{10}$) of Buchner and Binswanger, may be obtained by Phipson's process by macerating the bark for three or four days in carbon disulphide, then permitting the liquid to evaporate, exhausting the residue with alcohol, which leaves the fatty matter behind, evaporating the alcoholic liquid to dryness, and recrystallizing from ether. As thus obtained it is in fine yellow crystals, melting at about 226° C. (438.8° F.), and subliming in golden-yellow needles. It is insoluble in water, soluble in 160 parts of warm 80 per cent. alcohol, nearly insoluble in cold alcohol, soluble in hot fixed oils, petroleum benzin, and oil of turpentine. It communicates its color to cotton, silk, and wool. Faust (*A. Pharm.*, clxxxvii, 8) first proved the glucosidal character of frangulin by boiling it in alcoholic solution with hydrochloric acid, obtaining glucose and *frangulinic acid*, $C_{14}H_8O_4$. This forms fine microscopic needles of reddish color, fusing at 248° to 250° C. (478.4°–482° F.). Liebermann and Waldheim (*Ber. d. Chem. Ges.*, 9, p. 1775) obtained in this decomposition instead of frangulinic acid, *emodin*, $C_{15}H_{10}O_5$, trioxymethylanthraquinone. Frangulinic acid, on the other hand, would be a dioxyanthraquinone and an isomer of alizarin. Schwabe, in 1888, also found that *emodin* and *rhamnodulcite* were the decomposition products of *frangulin*, to which latter he gave the formula $C_{21}H_{20}O_9$, instead of that given above by Buchner. (Planchon et Collin, *Drogues Simples* (1896), vol. ii, 590.) E. Amweg has devised a method of separating the glucosides from frangula, cascara and rhubarb by extraction with solvents; he uses, 1, benzene; 2, a mixture of two parts of benzene, and one part of absolute alcohol, and 3, alcohol (60 per cent.) (*Ap. Ztg.*, 1897, 747.) Kubly isolated a crude acid which, when purified, he termed *frangulic acid;* Amweg regards this acid as a decomposition product and calls it *pseudo-frangulin*, this when hydrolyzed becomes *pseudo-emodin*. The emetic action of the green bark is attributed to a hydrolytic ferment, which is destroyed by heating. (*P. J.*, 1898, 24.)

Tschirch and Bromberger state that the bark of *Rhamnus cathartica* was found to contain *rhamnosterin, rhamnofluorin, emodin, chrysophanol* and *d-glucose*. (*S. W. P.*, 1912, v. 50, pp. 193–197.)

Uses.—In its fresh state this drug is very irritant to the gastro-intestinal mucous membrane, producing, when taken in sufficient quantity, violent catharsis, accompanied by vomiting and much pain. During drying it is said to lose much of its irritant power, and the dried bark is affirmed to resemble rhubarb in its action. The U. S. P. VIII required that the bark should be at least one year old, but this requirement does not appear in the U. S. P. IX. A *decoction* (an ounce to the pint) may be used in tablespoonful doses, or a dessertspoonful of an *elixir*, made by mixing four fluidounces of the fluidextract with twelve of elixir of orange, may be employed.

Dose, of frangula, fifteen to thirty grains (1–2 Gm.).

GALLA. U. S., Br.

NUTGALL Gall. [Aleppo Galls, Smyrna Galls]

(găl'la)

"Excrescences on the young twigs of *Quercus infectoria* Olivier and other allied species of *Quercus* (Fam. *Fagaceæ*), induced by the punctures on the leaf-buds and by the deposited ova of *Cynips tinctoria* Hartig (Order *Hymenopteræ*). Not more than 5 per cent. of Galls float in water." *U. S.* "Galls are excrescences on Quercus infectoria, *Olivier*, resulting from the deposition of the eggs of Cynips gallæ tinctoriæ, *Olivier*." *Br.*

Galls, Syrian Galls; Galla Halepensis, s. Turcica, s. Levantica, s. Tinctoria, s. Quercina; Galle de Chêne, d'Alep, *Fr. Cod.;* Noix de Galle, *Fr.;* Gallæ, *P. G.;* Galläpfel, Gallen, *G.;* Noce di galla, *It.;* Agalla, *Sp.*

Many plants, when pierced by certain insects, particularly those of the genus *Cynips*, are affected at the points of puncture with a morbid action, resulting in excrescences, which, as they are derived from the juices of the plant, partake more or less of its chemical character. Most of the oaks are occasionally thus affected, and the resulting excrescences, having in a high degree the astringency of the plant, have been employed for various practical purposes. They are known by the name of *galls*, a term which, as well as their use in medicine, has been handed down from the ancients. *Quercus infectoria, Q. ægilops, Q. excelsa, Q. Ilex, Q. Cerris*, and *Q. Robur* have been particularized as affording this product; but it is now generally admitted, on the authority of Olivier, that the official galls are derived chiefly, if not exclusively, from *Q. infectoria*. Under the name of *Chinese galls*, a product has been brought from China, supposed to be caused by an insect allied to the aphis, as such an insect has been found in the interior of them. They are irregularly spindle-shaped, often more or less bent, with obtusely pointed protuberances, about two inches long by an inch in diameter at the central thickest part, of an ash color and a soft velvety feel, very light, hollow, with translucent walls about a line in thickness, of a slight odor recalling that of ipecac, and a bitter astringent taste. From an examination of fragments of leaves and petioles found among these galls, Schenck concluded that the tree on which they

are found is a species of Rhus; but according to Decaisne, their true source is probably the *Distylium racemosum* of Zuccarini, a large tree of Japan, the leaves of which produce a velvety gall, resembling the one in question. (Guibourt, *Hist. Nat. des Drogues,* 1850, iii, 703.) Daniel Hanbury asserts that this opinion of Decaisne is erroneous (*P. J.,* Feb., 1862, p. 421), as in his examination of the packages imported from China and Japan he has found remains of different parts of a species of *Rhus,* but never any of a *Distylium.* Besides, the form of the galls of the *Distylium,* as figured by Siebold and Zuccarini, is entirely different. The species of *Rhus* which yields the commercial Chinese galls is the *R. semialata* Murray. The Chinese make great use of this product both in dyeing and as a medicine. L. A. Buchner, Jr., has found it to contain 65 per cent. of tannic acid identical with that of the official galls. (*Ph. Cb.,* July, 1851, p. 526.) It is recommended by Stenhouse for the manufacture of gallic acid, being preferable for this purpose to the official galls, in consequence of its less amount of coloring matter. (*P. J.,* Dec., 1862.) An inferior kind of galls is produced in great quantities in England, by the attack of the *Cynips kollari* of Hartig, upon the common English oak; but they have been ascertained to contain little tannic acid, and are of little value.

Quercus infectoria, or the so-called *dyer's oak,* is a small tree or shrub, with a crooked stem, seldom exceeding six feet in height. The leaves are petiolate, obtusely toothed, smooth and of a bright-green color on both sides. The acorn is elongated, smooth, two or three times longer than the cup, which is sessile, somewhat downy, and scaly. This species of Quercus grows, according to Olivier, throughout Asia Minor, from the Archipelago to the confines of Persia. M. Kinnier found it also in Armenia and Kurdistan; Hardwicke observed it growing in the neighborhood of Adwanie, and it probably pervades the middle latitudes of Asia.

The gall originates from the puncture of the *Cynips tinctoria* Hartig, a hymenopterous insect or fly, with a fawn-colored body, dark antennæ, and the upper part of its abdomen shining brown. The insect pierces the shoots and young boughs, and deposits its egg in the wound. This irritates the part, and a small tumor quickly rises, which is the result of a morbid growth, exhibiting various cells under the microscope, but no proper vegetable fiber. The egg grows with the gall, and is soon converted into a larva, which feeds upon the vegetable matter around it, and thus form a cavity in the center of the excrescence. The insect at length becomes a fly, and escapes by eating its way out. The galls are in perfection when fully developed, before the egg has been hatched or the fly has escaped. Collected at this period, they are called, from their dark color, *blue, green,* or *black galls,* and are most highly esteemed. Those which are gathered later and have been injured by the insect are *white galls.* They are usually larger, less heavy and compact, and of a lighter color than the former.

The galls collected in Syria and Asia Minor are brought to this country chiefly from the ports of Smyrna and Trieste, or from London. As they are produced abundantly near Aleppo, it has been customary to designate them by the name of that town, though the designation, however correct it may formerly have been, is now wholly inapplicable, as they are obtained from many other places, and the product of different parts of Asiatic Turkey is not capable of being discriminated, at least in our markets. Great quantities of galls, very closely resembling those from the Mediterranean, have been brought to the United States from Calcutta. Royle states that they are taken to Bombay from Bussorah through the Persian Gulf. We are, nevertheless, informed that galls are among the products of Moultan. Those of France and other southern countries of Europe have a smooth, shining reddish surface, are little esteemed, on account of their small yield of tannin, and are seldom brought to the United States.

Properties.—Galls are "nearly globular, from 0.8 to 2.2 cm. in diameter; externally blackish-olive-green or blackish-gray, more or less tuberculated on the upper portion, the basal portion being nearly smooth and contracted into a short stalk; heavy, sinking in water, excepting the smaller galls; fracture short-horny; internally grayish or dark brown, consisting of a central portion slightly radiating and resinous, occasionally hollow and traversed by a narrow radial canal extending to the exterior as shown by the perforation in the whole gall; odor slight; taste strongly astringent. The powder consists of numerous fragments of thick-walled starch-bearing parenchyma; starch grains numerous; more or less free in the powder and varying in shape from spherical or ellipsoidal to polygonal, and from 0.005 to 0.03 mm. in diameter; stone-cells few, resembling those found in fruits and seeds, varying considerably in shape and size, and from 0.025 to 0.3 mm. in length; occasional fragments with spiral or reticulate tracheæ; fragments mounted in dilute ferric chloride T.S. assume a deep blue or greenish-blue color. Macerate 0.5 Gm. of the powdered Nutgall with 2 mils of alcohol for a few minutes, add 500 mils of water, stir the mixture well for five minutes and filter. Take 1 mil of the light yellowish-brown solution, and dilute it with 10 mils of water; it shows a distinct blue or violet-blue color upon the addition of a drop of ferric chloride T.S." *U. S.*

"Hard, heavy, subglobular, from twelve to eighteen millimetres or more in diameter, tuberculated on the surface, the tubercles and intervening spaces being smooth; dark bluish-green or dark olive-green externally, yellowish or brownish-white within, with a small central cavity. Galls sink in water and exhibit no perforation. No odor; taste intensely astringent." *Br.*

The best are externally of a dark bluish or lead color, sometimes with a greenish tinge,

internally whitish or brownish, hard, solid, brittle, with a flinty fracture, a striated texture, and a small spot or cavity in the centre, indicating the presence of the undeveloped or decayed insect. Their powder is of a light yellowish-gray. Those of inferior quality are of a lighter color, sometimes reddish or nearly white, of a loose texture, with a large cavity in the centre, communicating externally by a small hole through which the fly has escaped.

Kraemer (*Bot. Gaz.*, 1900, p. 275) made a microchemical study of American galls. These closely resemble the Aleppo variety and are formed on *Quercus coccinea* Muench and *Q. imbricaria* Michx. by *Cynips aciculata*. Kraemer found the chemical constituents to vary with the development of the insects. At the chrysalis stage gallic acid is more abundant than when the winged insect is developed. Texas galls are formed on the live oak (*Q. vireus*), California oak balls are formed on *Q. lobata*.

Galls are formed on a number of trees and shrubs, including oaks, rhus, rhododendron, juniper, eucalyptus and sage. Hartwich (*Arch. d. Pharm.*, 1905, p. 584) illustrates these several varieties and discusses their composition. Richter gives minute descriptions of the origin, structural characteristics and microscopical appearance of galls in *Ph. Zentralh.*, 1912, p. 533. Feist and Haun have published (*A. Pharm.*, 1913, v. 251, p. 468) an article on the constitution of the tannin in Turkish and Chinese galls.

Galls have a bitter, very astringent taste, and when whole are inodorous or nearly so, but bruised or in powder they have a decided and peculiar though not very strong odor. The tannin of galls, usually known as *gallo-tannic acid*, appears to exist in the galls, in part at least, as a glucoside, but one very easily broken up by ferments like pectase into glucose and *di-gallic acid*, $C_{14}H_{10}O_9$, which is the material, therefore, extracted from the galls. This digallic acid may be considered as the anhydride of *gallic acid*, $C_7H_6O_5$, formed from two molecules of this latter by the elimination of one molecule of water. Commercial tannin yields from 0 to 22 per cent. of glucose, showing the presence of varying amounts of the unaltered glucoside. Galls yield, on an average, from 65 to 77 per cent. of tannin. (See *Acidum Tannicum* and *Acidum Gallicum*, see also "The Tannins," by Henry Trimble, J. B. Lippincott Co., 1894.) All the soluble matter of galls is taken up by forty times their weight of boiling water, and the residue is tasteless. Alcohol dissolves seven parts in ten, ether five parts. A saturated decoction deposits upon cooling a copious pale-yellow precipitate. The infusion or tincture affords precipitates with sulphuric and hydrochloric acids, lime water, and ammonium and potassium carbonates, with solutions of lead acetate and subacetate, copper and iron sulphates, silver and mercuric nitrates, and potassio-antimonyl tartrate; with solution of gelatin; and with the infusions of Peruvian bark, calumba, opium, and many other vegetables, especially those containing alkaloids, with most of which tannic acid forms insoluble compounds. The infusion of galls reddens litmus paper, is rendered orange by nitric acid, milky by mercuric chloride, and has its color deepened by ammonia, but yields no precipitate with either of these reagents. Zinc sulphate was said by A. T. Thomson to slowly occasion a precipitate, but this result was not obtained by Duncan. Infusion of galls is rendered more permanent by the addition of 10 per cent. of glycerin.

A variety of galls was imported into Germany, which was said to be derived from Central Asia, especially from the provinces of Khokan, Khiva, and Bokhara, where they are used in dyeing. They are of various forms, some being long, others round, cylindrical, or angular, and sometimes they are grouped upon a single stalk, and covered with little elevations. They differ from all other galls by their color, being on one side yellow, and on the other of a fine red. Most of them present a little opening, and in the interior are eggs and larvæ of a peculiar species of aphis. They have yielded, on analysis, 43.10 per cent. of tannin, 3.03 of a green wax, 16 of cellulose, and an undetermined quantity of fecula and volatile oil. (R. Palne, *J. P. C.*, April, 1873.)

From the so-called gall-wax of certain kinds of galls, M. Nierenstein obtained a nitrogenous constituent, $C_{13}H_{17}O_6N$, which is probably a lævorotatory *galloleucin*. (*Z. Phys. Ch.*, 92, 53.)

Uses.—Galls have a powerfully astringent action, but are no longer prescribed internally. *Aromatic Syrup of Galls* is sometimes prescribed. For a process, see U. S. Dispensatory, 19th ed., p. 574. Nutgalls may be used externally for the same purposes as tannic acid.

Dose, five to fifteen grains (0.3–0.9 Gm.).

GAMBIR. U. S.

GAMBIR [Pale Catechu]
[To replace Catechu, U. S. 1890]

(găm'bĭr)

"A dried extract prepared from decoctions of the leaves and twigs of *Ourouparia Gambir* (Hunter) Baillon (Fam. *Rubiaceæ*)." *U. S.* (See *Catechu* and *Catechu Nigrum*, page 305.)

Catechu Pallidum, Terra Japonica, Gambier, Cutch; Gambir Cubique, *Fr.;* Catechu, *P. G.;* Katechu, Gambir-Catechu, *G.;* Catecu, *It., Sp.*

Ourouparia Gambir (Hunter) Baillon (*Uncaria Gambier* Roxb.) This is a climbing shrub with slender stems somewhat thickened at the nodes; leaves ovate or oblong, entire, rounded at the base but abruptly attenuated at the summit, opposite and stipulated, smooth on both sides. The flowers are small, crowded into a dense globular head on a hairy receptacle; the flower heads are borne on long axillary peduncles which bear in the middle a whorl of bracts. At the point where these bracts occur

the peduncle breaks after the falling of the inflorescence and the remainder of the peduncle becomes elongated and curved into hooks by means of which the plant climbs. Corolla gamopetalous, trumpet-shaped, tube slender; fruit one inch long, pericarp dry, dehiscing vertically into two valves; seeds very numerous.

It is a native of Malacca, Sumatra, Cochin-China, and other parts of Eastern Asia, and is largely cultivated in the islands of Bintang, Singapore, and Prince of Wales. The gambir is prepared by lopping off the leaves, shoots, and twigs of the plant, chopping them into pieces, and throwing them into an iron pot filled with boiling water. When the leaves are exhausted and the liquid sufficiently thick, it is poured into small wooden tubs, and so soon as sufficiently cool, a half-closed hand is plunged into the semi-fluid mass and a piece of light wood shaped like an elongated dice box rapidly worked up and down in the hollow formed by the hand. The extract begins to thicken by a process which is compared to crystallization. The mass is finally turned out, and cut into cubes, which are put upon trays and smoke-dried. (See also *P. J.*, 1892, 1003.) This extract, which is known by the native Malays as *pinang* or *siren* was first brought to the attention of the profession by Campbell.

The amount of gambir exported from the Straits Settlements in 1910 amounted to 40,000,000 pounds, of which about 15,000,000 pounds was shipped to the United States.

Most of the commercial article is shipped from Singapore to London and Hamburg. The natives of Malay distinguish four different kinds: 1. *Gambir bulat* or *round Gambir*, which occurs in biscuit-like pieces and is mostly used for chewing. 2. *Gambir papan* or *table Gambir* which occurs in yellowish-brown thin tablets and is also used in chewing. 3. *Gambir paku* (*nail* or *finger Gambir*) which occurs in long black sticks resembling licorice extract. 4. *Gambir dutoor* or *cube Gambir*. The latter is the form in which it is usually found in commerce. Gambir is also imported in large blocks, being used in this form for dyeing and tanning.

Properties.—Gambir is "usually in cubical or rectangular pieces from 20 to 30 mm. in diameter; externally pale grayish-brown to reddish-brown, more or less dull and porous; friable; internally of a light brown or dull earthy color; inodorous; taste bitterish and very astringent. Upon scraping a piece of Gambir and mounting the separated fragments in hydrated chloral T.S. and examining them under the microscope, numerous acicular crystals, from 0.01 to 0.03 mm. in length, separate at the edges of the fragments and gradually dissolve, leaving a few, thick-walled, non-glandular hairs which, when entire, may be 0.35 mm. in length; a few fragments of leaves may also be present showing either epidermal cells or small narrow tracheæ with spiral or annular markings; a few starch grains either single or compound, of variable shapes and from 0.005 to 0.015 mm. in diameter; a number of bacteria may also be present. Macerate 1 Gm. of Gambir with 50 mils of water, and filter; the pale yellowish-brown solution obtained gives an intense, green color with dilute ferric chloride T.S.; but yields no precipitate with copper sulphate T.S. Not less than 65 per cent. of Gambir is soluble in water and not less than 60 per cent. is soluble in alcohol. Gambir yields not more than 9 per cent. of ash." *U. S.*

The microscopical appearance of gambir is very characteristic and Brumwell (*J. S. C. Ind.*, 1911, p. 475) illustrates the appearance of commercial specimens. Gambir is light and porous, so that it floats when thrown in water. It is partially soluble in cold water, and almost wholly so in boiling water, which deposits a portion upon cooling. Duhamel, Ecky, and Procter dissolved 87.5 per cent. of it in cold water by means of percolation. (*A. J. P.*, xvi, 166.) Nees von Esenbeck found it to consist of from 36 to 40 per cent. of *catechutannic acid*, a peculiar principle called *catechuin*, *catechin*, or *catechuic acid*, gum or gummy extractive, a deposit like cinchonic red, and 2.5 per cent. of lignin. *Catechin*, when perfectly pure, is snow-white, of a silky appearance, crystallizable in fine needles, melting at 217° C. (422.6° F.), unalterable in the air if dry, fusible by heat, very slightly soluble in cold water, with which it softens and swells up, soluble in boiling water, which deposits it on cooling, and soluble also in alcohol and ether. It very slightly reddens litmus paper, and, though coloring solution of chloride of iron green, and producing with it a grayish-green precipitate, differs from tannic acid in not affecting a solution of gelatin. The very great discordance of different authors as to its formula seems to be explained by some experiments of Etti (*Ann. Ch. Ph.*, 186, p. 327), who showed that *catechin*, $C_{15}H_{18}O_8$, readily gives at 100° C. (212° F.), or even when kept for some time over sulphuric acid, an anhydride, $C_{30}H_{34}O_{15}$, and at 160° C.(320° F.) a second anhydride, $C_{30}H_{32}O_{14}$, which, mixed in varying proportions, explain the varying results. Gautier (*Bull. Soc. Chim.*, 30, 567) finds three different catechins separable by their different solubility in water, all of them crystallizable. These are: *a-catechin*, $C_{40}H_{38}O_{18} + 2H_2O$, melting at from 204° to 205° C. (399.2°–401° F.), and present in gambir to the amount of 12 per cent.; *b-catechin*, $C_{47}H_{38}O_{16} + H_2O$, melting at from 176° to 177° C. (348.8°–350.6° F.), and 2 per cent. present in gambir; and *c-catechin*, $C_{40}H_{38}O_{18} + H_2O$, melting at 163° C. (325.4° F.), and present in gambir to the amount of 6.5 per cent.

Perkin and Yoshitako (*P. J.*, 1902, p. 530) have made an elaborate investigation of gambir and acacia catechus. They find three catechins, designated respectively as (*a*), (*b*), and (*c*). Catechin (*b*), $C_{15}H_{14}O_6 + 4H_2O$, occurs in air dried, colorless needles, melting at 175° to 177° C. (347°–350.6° F.), and gives on fusion with alkali, phloroglucinol, protocatechuic acid, and an acid resembling acetic acid. Catechin (*c*), $C_{15}H_{14}O_6$, air dried, contains no water of

crystallization and forms colorless prisms, melting at 235° to 237° C. (455°–458.6° F.). Catechin (*a*), $C_{15}H_{14}O_6 + 3H_2O$ (or less probably $C_{14}H_{14}O_6 + 3H_2O$), air dried, forms colorless needles, melting at 204° to 205° C. (399.2°–401° F.).

Good gambir should occur in a hard compact mass, breaking up, when the adhering mat is removed, into distinct cubes of a brownish-black color externally, and a deep mahogany-red with an occasional streak of yellow internally. It should not steam when the mat is opened. From this quality it grades down to a stuff which has been prepared by mixing the material obtained by reboiling the exhausted leaves with various mixtures. This lowest grade is not in cubes, steams when opened, frequently shows large patches of black or dirty blue color, and often has a sour fetid odor; its color varies from black to light-brown.

The varieties between the two extremes are very great; sometimes gambir occurs in solid mass of fair quality; sometimes the cubes are of extraordinary size, and of a color varying from a dirty white to a very pale yellow. At the Edinburgh Forestry Exhibition in 1885 the Maharajah of Johore exhibited specimens labelled "gambir produced in Johore." The first quality, which was "*makan*" (for eating), was in regular cubes, externally cassia-brown color, internally pale cinnamon brown, and yielded 32 per cent. of tannic acid; the second quality was in badly formed cubes, externally brown and black, internally cinnamon, and yielded 30 per cent. of tannic acid; the third quality was in dull-brown, well-shaped cubes, internally pale brown, and yielded 19 per cent. of tannic acid. The oblong or *parallelopiped gambir* was of a uniform dull brown, very hard and strong, and yielded only 2 per cent. of tannic acid. MacEwan believes that the low percentage of tannin was due to the decoction not having been subjected to prolonged boiling, which favors the decomposition of catechin, with the formation of catechu-tannic acid. None of the finest varieties of gambir, such as are used by the natives for chewing, occur to any extent in American commerce. Prebble records his examination of a cube gambir of fine appearance which contained a large percentage of starch. (*P. J.*, 1893, 21.)

Enormous quantities of gambir are used both in Europe and America in tanning, calico printing, dyeing, as an ingredient in boiler compounds for preventing the hard scaly incrustation caused by certain kinds of water, and other art processes requiring tannic acid.

Vanderkleed and E'we call attention to the fact that the apparent alcohol soluble content of gambir may be unduly raised by the high moisture content of some of the commercial varieties, which they report as containing over 21 per cent. of moisture, all of which would be calculated in the alcohol soluble extractive by the ordinary methods in which no allowance is made for water. (*J. A. Ph. A.*, 1914, 1685.)

Uses.—Gambir is a serviceable remedy in those cases where astringents are indicated. The complaints to which it is best adapted are *diarrhea* dependent on debility or relaxation of the intestinal mucous membrane, and *passive hemorrhages*, particularly from the uterus. A small piece held in the mouth and allowed slowly to dissolve is an excellent remedy in *relaxation of the uvula* and the *irritation of the fauces* and *troublesome cough* which depend upon it. Applied to *spongy gums*, in the state of powder, it sometimes proves useful; and it has been recommended as a dentifrice in combination with powdered charcoal, Peruvian bark, myrrh, etc.

Dose, from ten grains to half a drachm (0.65–2.0 Gm.), which should be frequently repeated, and is best given with sugar, gum arabic, and water.

GELATINUM. U. S., Br.

GELATIN Gelat.

(ǧe-lăt'ĭ-nŭm)

"The purified product obtained from animal tissues, as skin, ligaments, and bones, by treatment with boiling water." *U. S.* "Gelatin is the air-dried product obtained by the action of boiling water on animal tissues such as skin, tendons, ligaments, and bones." *Br.*

Gelatine; Gélatine animale, *Fr. Cod.*; Colle de Flandre purifiée, *Fr.*; Gelatina alba, *P. G.*; Weisser Leim, Gelatine, Gallerte, *G.*; Gelatina, *Sp.*

Gelatin is the term applied to purified forms of the substance ordinarily known as *glue*, and the bones and animal matter from which the best qualities of gelatin are prepared are carefully selected so as to be free from decomposed products and odorous substances. The hot solution of gelatin must be thoroughly clarified if the so-called sparkling gelatin is to be made.

The *collagens* are a class of albuminoids abundant in bones, skin, tendons, cartilage and similar tissues of animals. These collagens unite with water at high temperatures, producing the compounds known respectively as glue and gelatin which differ from each other mainly in the character of the raw stock from which they are manufactured and also in the relative amounts of *glutin* and *chondrin* which they contain; glutin being present in higher proportions in glue, to which it imparts its great adhesive power and chondrin giving to gelatin its greater gelatinizing power. Among the commercial varieties of these substances may be mentioned *hide glue* and *bone glue*, which are commercially the most important.

On account of the tendency to decompose during the process of manufacture it is sometimes the practice to employ preservatives such as sulphurous acid, which, being frequently used in excessive amounts, remain in the finished product as contaminating substances. Sometimes metallic impurities, as lead, copper, zinc, and arsenic, are present from the apparatus or

substances used during the manufacture of the gelatin.

After the gelatin solution has been purified by the use of animal charcoal or other appropriate means, it is brought to the proper degree of concentration and is then allowed to solidify or gelatinize. It is now cut up into slabs which are rapidly dried in long, continuous mechanical drying machines where it is supported upon netting to allow free access of the warm, dry air currents which pass over it.

The surface of sheet gelatin is covered with lozenge-shaped marks, due to impressions left by the knotted netting upon which it is dried. Shred gelatin is made by cutting sheet gelatin into very narrow shreds by a shearing-machine. (See *Nat. Drug.*, 1894, 134.) *Gelatose* and *paragelatose* are terms used by Dastre and Floresco to define gelatin which has lost its power of "gelatinization" through the action of ferments or microbes, saline solutions, or the prolonged action of boiling water. (*P. J.*, 1895, 454.)

Properties.—It is officially described as "an amorphous solid, in sheets or flakes or in ground, powdered or shredded form, colorless or slightly yellowish, and having a very slight, characteristic odor and taste; unalterable in the air when dry, but decomposing when moist or in solution. Gelatin is insoluble in cold water but swells and softens when immersed in it, gradually absorbing from 5 to 10 times its own weight of water; soluble in hot water, acetic acid or glycerin; insoluble in alcohol, chloroform, ether, benzene, carbon disulphide or fixed or volatile oils. An aqueous solution of Gelatin (1 in 5000) is at once rendered turbid by the addition of tannic acid T.S. A hot solution of Gelatin in distilled water (1 in 40) is free from putrid odor, and is not more than slightly acid to litmus; it appears not more than slightly opalescent in a stratum 2 cm. in thickness, and, on cooling to 6° C. (42.8° F.) and standing for several hours, it forms a firm, transparent or translucent jelly. Incinerate about 0.5 Gm. of Gelatin; not more than 2 per cent. of ash remains. A solution of the ash in 25 mils of distilled water, made with the aid of heat and a few drops of hydrochloric acid, does not respond to the Test for heavy metals (see Part III, Test No. 3). Heat 1.5 Gm. of Gelatin with 30 mils of hydrochloric acid (1 in 4) in a 150 mil Erlenmeyer flask on a water bath, and, when the Gelatin has dissolved, add 3 mils of saturated bromine water and heat it on a water bath for fifteen minutes, shaking the flask occasionally. Then add 0.5 Gm. of potassium iodide and follow it immediately with 0.5 mil of a 25 per cent. solution of stannous chloride. Heat the solution for five minutes on a water bath, cool and subject it to the Test for arsenic (see Part III, Text No. 1). The stain produced, if any, is not greater than that produced in a test made with the same quantities of the reagents to which 2 mils of the standard arsenic test solution (see Part III, Test No. 1) has been added. Dissolve 20 Gm. of Gelatin in 150 mils of hot distilled water in a flask having a round bottom and a long neck, add 5 mils of phosphoric acid and 1 Gm. of sodium bicarbonate, and at once connect the flask with a condenser. Distil 50 mils, receiving the distillate under the surface of 50 mils of tenth-normal iodine V.S. Acidulate the distillate with a few drops of hydrochloric acid, add 2 mils of barium chloride T.S., and heat on a water bath, until the liquid is nearly colorless. The precipitate of barium sulphate, if any, when filtered, washed and ignited, weighs not more than 0.0015 Gm., corresponding to not more than 0.002 per cent. of *sulphur dioxide* in the Gelatin, correction being made for any sulphate which may be present in 50 mils of the tenth-normal iodine V.S.

"NOTE.—Gelatin used for making capsules for medicines contains not more than 0.15 per cent. of sulphur dioxide." *U. S.*

"In almost colorless, translucent sheets or shreds. Insoluble in *alcohol* (90 per cent.) and in *ether;* soluble in *acetic acid.* A solution in hot *water* (1 in 50) is inodorous and solidifies to a jelly on cooling. An aqueous solution yields a precipitate with *solution of tannic acid,* but not with solutions of other acids, or with dilute solution of *alum, solution of lead acetate,* or *T. Sol. of ferric chloride.* Ash not more than 2 per cent." *Br.*

Gelatin is largely used for making *capsules.* Certain medicines are so offensive to the taste, and consequently so likely to cause nausea, that it is highly desirable to administer them in such a way as to prevent their contact with the tongue and palate. This object is fully accomplished, so far as regards many disagreeable liquid medicines, by the use of the capsules of gelatin. A polished bulb of iron, ivory, or bone, of the size and shape of the capsules required, and connected by a slender rod with a handle, is first greased by rubbing with an oiled cloth, and then dipped into a solution of gelatin made by heating six parts of pure gelatin with one of sweetened water. Upon being withdrawn, it is held for a short time so as to allow the excess of the solution to run off, and then fixed with the handle in a board, the coated bulb being upward, until the coating becomes cold and firm. The capsule is now removed by the fingers, and further dried by exposure on a tray. A number of capsules having been prepared, they are placed each in a small cell upon a board, with their mouths upward, and the liquid they are to contain is introduced by means of a syringe with a fine point. Their mouths are then closed with a drop of the solution of gelatin applied by means of a stick or glass rod, which is afterwards strengthened by an additional coating, given by dipping the mouth of the capsule into the solution diluted with a little water. The capsules may be made of such a capacity as to contain from ten to fifteen grains of copaiba or other liquid. Capsules are now largely used for enclosing dry powders like quinine, etc. These are ovoid in shape, and after being filled with the powder by the pharmacist, are closed by putting upon

the open end a rounded gelatin cap and pressing it down tightly. When so-called *soft capsules* are desired, a small quantity of glycerin is introduced into the gelatin mass; this makes the film elastic by preventing its drying completely. Gelatin capsules are now made in enormous quantities by machinery.

Formalized gelatin is but very slightly or not at all affected by the gastric juice, but is slowly dissolved in the intestines. Advantage has been taken of this fact to manufacture capsules for the administration of drugs which it is desirable should not come in contact with the gastric mucous membrane. A special brand of such capsules is on the market under the name of *glutoid capsules.* These are called *enteric capsules.*

Scoville (*J. A. Ph. A.*, 1915, p. 1243) recommends that the sealed capsules be immersed in a 1 per cent. aqueous formaldehyde solution for thirty seconds, then dried quickly and allowed to stand two weeks before use. Capsules so treated will remain enteric for about one year, but if stronger formaldehyde solutions are used or the time of treatment extended, the capsules, after standing for a few days, become insoluble in the intestines.

Uses.—In 1896 Dastre and Floresco (*C. R. S. B.*, 1896, ii, iii), while engaged in a research of the physical properties of gelatin, made the observation that, after a solution of gelatin had been injected into a vein, the blood of a dog coagulated almost instantaneously. This observation has led to an immense amount of study concerning the effect of gelatin administered by various channels upon the coagulability of the blood. It is well established that solutions of gelatin injected either intravenously or subcutaneously cause a great reduction in the time required for the blood to clot. Unfortunately, because of the liability of gelatin to contamination with tetanus, these injections are not permissible in human medicine. Two methods have been suggested to obviate the difficulty, one is to sterilize the gelatin, by subjecting to relatively high temperatures on repeated occasions, and the other to exhibit it by the mouth. When gelatin is eaten it undergoes a process of digestion similar to that of the protein foods, being finally converted into a substance known as *gelatose,* which differs from gelatin in that solutions of it do not gelatinize on cooling. When boiled for a long period of time a somewhat analogous change in gelatin takes place. There has been some difference of opinion as to whether the loss of its gelatinizing power is accompanied by a loss of its therapeutic virtue. While the matter cannot be considered as finally settled the evidence is very strong that a solution of gelatin may be perfectly sterilized without losing its power of hastening coagulation. Although less firmly supported there is still strong reason for believing that the administration of gelatin by the mouth influences clotting of the blood in the same way. To what change in the blood is due the increased coagulability under the influence of gelatin is at present undetermined. The theory at one time advanced that the effects were due to the lime in the gelatin is too absurd to require contradiction. The most probable explanation is that of Moll (*W. K. W.*, 1903) that it increases the amount of fibrinogen.

Gelatin is used in medicine in all cases where increased coagulability of the blood is desirable, thus in various forms of internal *hemorrhage* as *hemoptysis, hematemesis,* or *menorrhagia,* it is one of the most valuable agents we possess; in various dyscrasias of the blood, such as *hemophilia* or *purpura hemorrhagica,* it has been employed with apparent great benefit. In certain types of *aneurism* it will apparently encourage the deposit of clot in the aneurismal sac. It has also been employed in the treatment of *diarrhea* and *mucous colitis* with asserted benefit.

The method of exhibiting the gelatin will vary greatly according to the condition for which it is employed. In local hemorrhages, as *epistaxis,* a warm 10 per cent. solution may be applied directly to the bleeding point; in *gastric ulcer* the administration by the mouth is probably the preferable method as a local action may be obtained in this manner. In internal hemorrhages when the bleeding is copious, the drug should generally be given hypodermically, as the absorption from the intestinal tract is too slow to be of service. The intravenous injection has in several instances caused fatal embolism and should, under no circumstances, ever be resorted to. For hypodermic administrations it is usually necessary to obtain one of the specially prepared sterilized forms of gelatin. These are generally marketed in the form of 10 per cent. solutions. Of this 10 per cent. solution from one to three fluidounces (30–90 mils) may be injected subcutaneously. In the slower forms of hemorrhage administration by the mouth should be tried first for obvious reasons. For this purpose from a half to two ounces (15.5–62 Gm.) of commercial gelatin may be dissolved in four or five times as much water, suitably flavored and seasoned, and allowed to cool and eaten in the same manner as ordinary table gelatin.

Dose, one-half to one ounce (15.5–31 Gm.).

Off. Prep.—Gelatinum Glycerinatum, *U. S.;* Suppositoria Glycerini, *Br.* (Vehicle for lamellæ in Br.)

GELATINUM GLYCERINATUM. U. S.

GLYCERINATED GELATIN Gelat. Glycerin.

(ge-lăt'i-nŭm glĭç-e-ri-nā'tŭm)

Gelatina Glycerinata, Gelatinum Glycerini; Glycerin Jelly; Gelée Glycérinée, *Fr.;* Glycerinleim, *G.*

* "Gelatin, *one hundred grammes* [or 3 ounces av., 231 grains]; Glycerin, *one hundred grammes* [or 3 ounces av., 231 grains], Water, *a sufficient quantity,* to make *two hundred grammes* [or 7 ounces av., 24 grains]. Pour upon the Gelatin sufficient Water, which has been previously boiled and cooled, to cover it; allow it to stand one hour; pour off the Water and allow the Gelatin to drain for a few minutes; then transfer it to a dish, add the Glycerin,

and heat it on a water-bath until the gelatin is dissolved. Strain the solution while hot, and transfer it to a tared dish, continue to heat on the water-bath until the product weighs *two hundred grammes* [or 7 ounces av., 24 grains]. When cold, cut the mass into pieces, and preserve them in well-closed containers." *U. S.*

This preparation was made official for the first time in the U. S. Pharm. VIII.

Uses.—Glycerinated gelatin is used as a vehicle in making gelatin suppositories, bougies, etc. The National Formulary IV introduced a class of preparations termed "*Glycerogelatins*," to be used in dermatological practice. (See Part III.)

GELSEMIUM. U. S. (Br.)

GELSEMIUM Gelsem. [Yellow Jasmine Root, Yellow Jessamine]

(ğĕl-sĕm'ĭ-ŭm)

"The dried rhizome and roots of *Gelsemium sempervirens* (Linné) Aiton filius (Fam. *Loganiaceæ*)." *U. S.* "Gelsemium Root is the dried rhizome and root of Gelsemium nitidum, *Michaux*." *Br.*

Gelsemii Radix, *Br.;* Gelsemium Root, Yellow Jasmine, Yellow Jessamine, Carolina or American Yellow Jessamine, Yellow or Evening Trumpet Flower; Gelsemium, *Fr. Cod.;* Jasmin sauvage, *Fr.;* Gelsemie, Giftjasmin, *G.;* Gelsemio, *Sp.*

The *yellow* or *Carolina Jessamine* (*Gelsemium sempervirens*) is one of the most beautiful climbing plants of our Southern States, ascending lofty trees, and forming festoons from one tree to another, and during its flowering season, in the early spring, scenting the atmosphere with its delicious odor. The stem is twining, smooth, and shining; the leaves perennial, opposite, nearly persistent, short, petiolate, lanceolate, entire, dark green above, and paler beneath; the flowers in axillary clusters, large, of a deep-yellow color, and fragrant, with a very small, five-leaved calyx, and a funnel-shaped corolla, having a spreading, five-lobed, nearly equal border. The fruit is a flat, compressed capsule, divisible into two parts, two-locular, and furnished with flat seeds, which adhere to the margins of the valves. The plant grows in rich, moist soils along the sea-coast from Virginia to the south of Florida and Texas. The flowers are said to be poisonous. *Gelsemium elegans* Benth., of upper Burma, is an extremely poisonous creeper which contains gelsemine or an allied alkaloid.

This official plant must not be confounded with the true yellow jasmine of Madeira, often planted in the Southern States, which is the *Jasminum odoratissimum* L., which also has very fragrant yellow flowers.

Properties.—It is officially described as: "Rhizome cylindrical, usually in pieces from 3 to 20 cm. in length and from 3 to 30 mm. in diameter; externally light yellowish-brown, longitudinally wrinkled, with purplish-brown longitudinal lines and transverse fissures; the upper surface with a few stem-scars, the under and side portions with numerous roots and root-scars; fracture tough, splintery; internally light brown or pale yellow, bark thin, wood distinctly radiate, excentral, pith disintegrated; odor slight; taste bitter. Roots light brown; fracture one-half transverse, the other oblique or splintery. Under the microscope, sections of the rhizome of Gelsemium show a strong development of cork, the walls being grayish or yellowish-brown and more or less lignified; a cortex made up chiefly of parenchyma containing starch and having in the outer portion small scattered groups of stone cells or sclerenchymatous fibers, and in the inner portion in the region of the medullary ray prisms of calcium oxalate; woody portion made up of broad wedges consisting of large tracheæ and fiber-tracheids separated by starch-bearing medullary rays, the innermost cells, or those nearer the pith, being strongly lignified, while the outermost layers, or those nearer the cortex, are non-lignified and may contain prisms of calcium oxalate; an internal phloem or sieve, the cells forming distinct, more or less rounded groups, the latter being partly surrounded by a thin-walled starch-bearing pith. The powder is dark yellow, tracheæ with bordered pores numerous, and conspicuous; spiral tracheæ few; bast-fibers and fiber-tracheids long and narrow, strongly lignified; starch grains spherical, from 0.004 to 0.008 mm. in diameter; calcium oxalate in monoclinic prisms from 0.015 to 0.03 mm. in length; occasional groups of stone cells or sclerenchymatous fibers, the walls being very thick, porous, and strongly lignified." *U. S.*

"In nearly cylindrical pieces about fifteen centimetres or more long, and usually from six to eighteen millimetres thick; occasionally with fibrous rootlets attached. Fracture splintery. In transverse section, a thin cortex, and a porous, yellowish, distinctly radiate wood with numerous, conspicuous, straight medullary rays. Rhizome usually with a brown or dark brownish-violet cork, often much fissured; nearly straight, and exhibiting silky fibres in the bast. Root yellowish-brown, finely wrinkled, and somewhat tortuous. Slightly aromatic odor; taste bitter." *Br.*

A microscopic character, said by Rothrock to be diagnostic, is the more or less complete division of the pith into four parts by plates of large thin-walled cells. (*A. J. P.*, 1884.) For elaborate study of structure of gelsemium, see *A. J. P.*, 1898, 398; *A. J. P.*, 1899, 422; *D. C.*, 1901, 244. Holm has contributed an article on the morphology of the overground portion of *Gelsemium sempervirens*. (*Merck's Rep.*, 1908, p. 86.) Tunmann (*Ph. Zentralh.*, 1907, p. 679) has made a pharmacognostic study of gelsemium and has proposed its identification through the microsublimation of æsculin. (See *Ap. Ztg.*, xxvi, p. 812.) Tutin (*P. J.*, Feb. 10, 1912) has shown that the sublimate ob-

tained by Tunmann from gelsemium root must have consisted of scopoletin. Tutin further states that "The detection of scopoletin in gelsemium may prove to be a valuable means of distinguishing this drug from others of a similar appearance, such as that derived from *Gelsemium elegans* Benth., but it is doubtful whether the sublimation method is the most convenient one. If 0.5 gramme of ground gelsemium be heated in a test tube with chloroform, the mixture filtered, and the filtrate shaken with water to which a few drops of dilute ammonia have been added, the aqueous layer, on separation, will be found to show a distinct, blue fluorescence, thus indicating the presence of scopoletin."

Sayre (*A. J. P.*, 1897, 8) found specimens of the root mixed with considerable proportions of the stem. Ingham (*A. J. P.*, 1897, 234) found that there was not much difference between the root and rhizome in alkaloidal value, but the stem does not appear to contain either gelsemine or gelsemic acid. (See also *A. J. P.*, 1897, 140.) Gelsemium yields its virtues to water, and readily to diluted alcohol. Analyzed by Henry Kollock, it was found to contain gum, starch, pectic acid, albumen, gallic acid, fixed oil, a fatty resin, a dry acrid resin, yellow coloring matter, volatile oil, extractive, lignin, a peculiar alkaloid called *gelsemine*, potassium, calcium, and magnesium salts, iron, and silica. The alkaloid, however, was not obtained sufficiently pure to admit of a full investigation of its properties. (*A. J. P.*, xxvii.) After Kollock's experiments, the alkaloid was obtained in a crystalline form, but still impure, by Maisch, from a tincture of the root, by a process of which a very brief abstract is given in *A. J. P.*, 1869, by C. L. Eberle, who in the same paper publishes the results of his own investigation. Eberle not only extracted gelsemine, but also satisfactorily established its alkaline properties, and proved that it was not contained in the wood of the root. Soon afterwards, the chemistry of yellow jasmine was more thoroughly investigated by Theo. G. Wormley. (*A. J. P.*, 1870.) He obtained pure gelsemine from the root and a peculiar acid, which he called *gelseminic* (gelsemic) *acid.*

Wormley obtained the acid by acidulating a concentrated aqueous solution of the drug and extracting with ether. (For details of his method, see *U. S. D.*, 19th ed., p. 578.) The acid, when pure, is colorless, inodorous, almost tasteless, and readily crystallizable, usually in groups or tufts of fine needles. The action of concentrated nitric acid upon gelsemic acid or any of its salts, produces a yellow, reddish, or red solution, which, if treated with ammonia in excess, becomes of a deep blood-red color, lasting for hours. The one-thousandth of a grain will exhibit these changes. Potassium, sodium, or ammonium hydroxide, added to the acid, cause it to become intensely yellow, and form with it highly fluorescent solutions. The acid is fusible, and, at a high heat, volatilizable without change. Robbins (*Deut. Chem. Ges.*, 1876, 1182), stated that it was identical with *æsculin* (the glucoside of the horse-chestnut), and gave it the formula $C_{15}H_{16}O_9 + 1\frac{1}{2}H_2O$.

But Coblentz (*Proc. A. Ph. A.*, 1897, 225) showed that it differs from æsculin in several particulars, and gave for its formula $C_{13}H_{11}O_5$, which melts at 206° C. (402.8° F.). E. Schmidt believes that Wormley's gelsemic acid is identical with *scopoletin* derived from scopola root, and gives the name as *β-methylæsculetin*, $C_9H_5(CH_3)O_4$.

Gelsemine was obtained by Wormley, from the concentrated extract from which gelsemic acid has been separated by ether, by rendering it slightly alkaline, then shaking out repeatedly with chloroform. It is a brittle, transparent solid, crystallizing with difficulty from alcohol. Boiling water sparingly dissolves it. It softens at 38° C. (100.4° F.), and fuses at 45° C. (113° F.). The pure base gives no color reaction with strong nitric acid, and the mixture is scarcely changed in color by heating. Strong sulphuric acid has no apparent action upon it; but if to the mixture a little manganic oxide be added and then rubbed with a glass rod, a deep crimson-red is obtained, passing to green. This reaction is so delicate, that it can be demonstrated with a solution of 1 in 100,000. If this reaction be performed upon the pure alkaloid, the color may be sufficiently intense to cause it to be mistaken for strychnine, but if a parallel experiment be carried on with strychnine, the two alkaloids cannot be mistaken, for the strychnine gives an intense purple, passing to red. Gerrard analyzed the alkaloid with care, and gives the formula $C_{12}H_{14}NO_2$ as its correct composition. F. A. Thompson (*Ph. Era*, 1887, p. 3) announced the presence of a second alkaloid, which he called *gelseminine*. After obtaining a solution of the alkaloids as sulphates he agitates it with an alkali and ether; the ethereal solution is shaken with water acidulated with hydrochloric acid, and the alkaloids are converted into hydrochlorides; gelseminine hydrochloride being easily soluble, and gelsemine hydrochloride less soluble, the latter is deposited on standing, and may be obtained pure by repeated crystallizations. He asserts that gelseminine differs greatly in physical and chemical properties from gelsemine, but, as he did not succeed in obtaining it absolutely pure, did not give the differences.

Sayre (*J. A. Ph. A.*, 1912, p. 458; 1913, p. 436; 1914, p. 314, and 1915, p. 60) has made a series of investigations of the principles of gelsemium based partly upon the work of C. W. Moore (*J. Ch. Soc.*, 1910, p. 2223), who reported gelseminine to consist of two amorphous alkaloids. Sayre found two alkaloids differing in physiological activity and color reactions, the one of which he called gelseminine (the former name for the combination of the two), and the other *gelsemoidine*, which was later changed to *sempervirine*. This latter alkaloid is similar in some of its properties to cinchonamine, par-

ticularly in the matter of the insolubility of its salts in water. Sayre also calls attention to the fact that the alkaloid commercially supplied under the name gelseminine is usually the crystalline alkaloid gelsemine. He states that the principles obtained by him show the following color reactions with sulphuric acid and manganic oxide: *Gelsemine,* at first crimson, then green, and finally yellow; *gelseminine,* at first brown, then pink, and finally yellow; *gelsemoidine,* at first purple and finally blue.

Uses.—According to the researches of Cushny (*A. E. P. P.,* 1892, xxxi, 49) gelseminine is so much more powerful than gelsemine that it is improbable that the latter alkaloid plays any part in the effect of the whole drug in mammals. Gelseminine is a depressant to the centers in the spinal cord and, in large doses, also paralyzes the peripheral motor nerves. Gelsemine acts, in the frog, much like strychnine, causing convulsions, by stimulating the spinal cord, which are followed by paralysis due to an effect on the motor nerves. In toxic quantities gelsemium lowers the blood pressure, probably by a direct action on the heart, but death is usually brought about through respiratory failure. When locally applied, or if given internally in poisonous dose, it causes dilatation of the pupil with loss of accommodation.

Formerly gelsemium was used as an arterial sedative and febrifuge in various sthenic *fevers,* but is probably useless for this purpose. Barthlow (*Pract.,* 1870, v, 200) has recommended it in spasmodic disorders, as *asthma* and *whooping cough.* It is, at present, rarely used except in the treatment of *neuralgias,* especially those involving the facial nerves. The mode of its action in these cases is obscure, but there is considerable clinical evidence of its utility.

The symptoms of gelsemium poisoning are: dizziness, dimness of vision, dilated pupil, general muscular debility, and universal prostration, reducing the frequency and force of the pulse, and the frequency of respiration. After very pronounced poisonous doses the symptoms which have just been enumerated are intensified: double or impaired vision, ptosis, dilated insensible pupils, falling of the lower jaw, loss of power of enunciation, and excessive muscular relaxation are associated with slow, labored breathing, which in some cases is interrupted by violent spells of dyspnœa; consciousness is long unimpaired, but is apt to be lost before death, and in rare cases unconsciousness has been present, even although recovery followed. Of the various symptoms of gelsemium poisoning the most characteristic are the dropping of the jaw and the ocular manifestations, combined with general muscular relaxation. The effects usually begin in half an hour, but sometimes almost immediately. According to Wormley, death has occurred at periods which vary from one to seven and a half hours. Twelve minims of the fluidextract are said to have proved fatal to a boy three years old, and thirty-five drops of a tincture of the bark have caused death in one hour and a half. In several instances a drachm of the fluidextract has, under treatment, been recovered from.

The treatment of poisoning by gelsemium should consist in evacuating the stomach, maintaining absolute rest in the horizontal position, keeping up the bodily temperature, if required, by external warmth, and administering spinal and arterial stimulants. We have very little experimental data as to the physiological antidotes to gelsemium. Our general knowledge indicates that ammonia, strychnine, and digitalis given hypodermically should be of service in the treatment of the poisoning.

Gelsemium should be administered in the form either of the tincture or of the fluidextract, the dose of the tincture being ten minims (0.6 mil), that of the fluidextract two minims (0.12 mil); to be repeated, if necessary, every 2, 4, or 6 hours, and gradually increased until the object is obtained, or some obvious effect is produced on the system.

Dose, of gelsemium, one to two grains (0.065–0.13 Gm.).

GENTIANA. U. S. (Br.)

GENTIAN Gentian. [Yellow Gentian Root]

(ǧĕn-tī-ā′nạ)

"The dried rhizome and roots of *Gentiana lutea* Linné (Fam. *Gentianaceæ*)." *U. S.*
"Gentian Root is the dried rhizome and root of Gentiana lutea, *Linn.*" *Br.*

Gentianæ Radix, *Br.;* Gentian Root, Bitter Root, Fel Root; Radix Gentianæ Rubræ (vel Luteæ vel Majoris); Gentiane (Racine), *Fr. Cod.;* Racine de Gentiane (de Gentiane jaune), Gentiane jaune, *Fr.;* Radix Gentianæ, *P. G.;* Enzian, Enzianwurzel, Bitterwurzel, Rother Enzian, *G.;* Genziana, *It.;* Genciana (Raiz de), *Sp.*

Gentiana lutea or *Yellow Gentian* is among the most remarkable of the species which compose this genus, both for its beauty and great comparative size. From its thick, long, branching, perennial rhizome, an erect, round stem rises to the height of three or four feet, bearing opposite, sessile, ovate, acute, five-nerved leaves of a bright-green color, and somewhat glaucous. The lower leaves, which spring from the root, are narrowed at their base into the form of a petiole. The flowers are large and beautiful, of a yellow color, peduncled, and placed in whorls at the axils of the upper leaves. The calyx is monophyllous, membranous, yellowish, and semi-transparent, splitting when the flower opens, and reflected when it is fully expanded; the corolla is rotate, and deeply divided into five or six lanceolate, acute segments; the stamens are five or six, and shorter than the corolla. The plant grows among the Apennines, the Alps, the Pyrenees, and in other mountainous or elevated regions of Europe. It is stated by Bourquelot and Hérissey that in order to develop the deep colored fracture preferred by many druggists the root is frequently submitted to fermentation by heaping it up into a mass which becomes

heated. Gentian root which has thus been treated is said to yield 27 per cent. less extractive than does that which has been properly dried. Further, even in the best commercial dried root the *sucrose, gentianose* and *gentiopicrin* of the fresh root are present only in extremely small amounts. (*J. P. C.*, 6, 16, 513.)

Several other species possess analogous virtues, and are used for similar purposes. The roots of *G. purpurea* L. and *G. punctata* L., inhabiting the same regions as *G. lutea*, and of *G. pannonica* Scopoli, growing in Austria, are said to be often mingled with the official, from which they are scarcely distinguishable. In fact the German Pharmacopœia permits the use of the rhizome and roots of these three species. The *G. macrophylla* of Pallas is used in Siberia.

G. quinquefolia L. (*G. quinqueflora* Lam.), growing throughout the Northern and Northwestern States, is said to be much used in domestic practice. In Europe the rhizome of the *G. asclepiadea* L. is often admixed with the official rhizome. According to Vogl, they can be detected by the abundance of lignified prosenchymatous elements and stone cells, the genuine powder containing scarcely any lignified elements other than large reticulated vessels. (*O. Z.*, 1903, 141.)

One indigenous species *G. Catesbæi* (now *G. Elliottii* Chapm.), growing in the Southern States, formerly had a place in the secondary catalogue of the U. S. Pharmacopœia, and is reputed to be but little inferior to the official species.

This plant, popularly called *blue gentian*, has a perennial, branching, somewhat fleshy root, and a simple, erect, rough stem, rising eight or ten inches in height, and bearing opposite leaves, which are ovate-lanceolate, acute, and rough on their margin. The flowers are of a palish-blue color, crowded, nearly sessile, and axillary or terminal. The divisions of the calyx are linear-lanceolate, and longer than the tube. The corolla is large, ventricose, plaited, and divided at its border into ten segments, of which the five outer are more or less acute, the five inner bifid and fringed. The number of stamens is five, and the stigmas are bifid. The capsule is oblong, acuminate, with two valves, and a single cell. *G. Elliottii* Chapm. grows in the grassy swamps from Virginia to Florida, where it flowers from September to December. It may be given in powder in the dose of from fifteen to thirty grains, or in the form of extract, infusion, wine or tincture.

Powdered gentian is not infrequently adulterated with ground olive stones, ground peanut shells, and even quassia root. These are all readily detected by means of their lignified tissues, which may be seen through the use of the microscope. Gadd and Gadd assert (*P. J.*, 1905, xxi, p. 439) that adulterations of Gentian are most readily detected by means of the microscope, but that good evidence of quality is also furnished by the yield of extract, which should be about 40 per cent.

Properties.—As found in commerce, gentian is in pieces of various dimensions and shapes, usually of considerable length, consisting sometimes of longitudinal slices, sometimes of the rhizome and root cut transversely. They are twisted, wrinkled externally, sometimes marked with close transverse rings of a grayish-brown color on the outside, yellowish or reddish within, and of a soft, spongy texture. It is officially described as occurring "in nearly cylindrical, sometimes branching pieces, of variable length, from 5 to 35 mm. in thickness; externally yellowish-brown, the rhizome portion annulate, the roots longitudinally wrinkled; fracture short and uneven when dry, but tough and flexible when damp; internally yellowish-brown, the bark from 0.5 to 2 mm. in thickness, separated from the somewhat spongy, woody portion by a dark brown cambium zone; odor strong, characteristic; taste slightly sweetish, then strongly and persistently bitter. The powder is light brown or yellowish-brown, consisting chiefly of parenchymatous cells with fragments of scalariform or reticulate tracheæ; starch grains few or none. Stone cells and sclerenchymatous fibers are absent. Gentian yields not more than 6 per cent. of ash." *U. S.*

"Parenchymatous tissue of rhizome and root abundant, containing small oil globules and minute crystals of calcium oxalate but not more than an occasional starch grain; vessels reticulated; no sclerenchymatous cells or fibres. Characteristic odor; taste at first slightly sweet but afterwards bitter. When 5 grammes of the powdered Root are macerated with 100 millilitres of *water* for twenty-four hours, shaken occasionally and filtered, 10 millilitres of the filtrate yield on evaporation in a flat-bottomed dish not less than 0.165 gramme of residue dried at 100° C. (212° F.). Ash not more than 6 per cent." *Br.*

Kromayer, in 1862, first obtained the bitter principle of gentian in a state of purity, and gave it the name of *gentiopicrin*, and the formula $C_{20}H_{30}O_{12}$. This principle has been found in many other species of the genus *Gentiana* and seems to be a characteristic principle of the genus. It is a glucoside, crystallizing in colorless needles, which readily dissolve in water. It is soluble in 95 per cent. alcohol, but in absolute alcohol only when aided by heat; it does not dissolve in ether. A solution of sodium hydroxide forms with it a yellow solution. Under the influence of diluted acids, gentiopicrin is resolved into glucose and an amorphous yellowish-brown neutral substance named *gentiogenin*. Fresh gentian roots yield about one-tenth per cent. of gentiopicrin. Another constituent is *gentianin* or *gentisin*, $C_{14}H_{10}O_5$. It forms tasteless, yellowish prisms, subliming with partial decomposition at a temperature over 300° C. (572° F.) sparingly soluble in alcohol, and with alkalies yields intensely yellow, crystallizable compounds, easily decomposed by carbon dioxide. Von Kostanecki (*A. J. P.*, 1891, p. 192), by boiling gentisin with hydriodic acid, succeeded in demethylating

it, and so obtained *gentisein*, $C_{13}H_8O_5$, which crystallizes with $2H_2O$ in fine straw-colored needles; these become anhydrous at 100° C. (212° F.). A triacetyl derivative was then formed from this gentisein. Gentisin is therefore the methyl ether of gentisein, and can be written $C_{13}H_5O_2\begin{cases}OCH_3\\OH\\OH\end{cases}$. Hlasiwetz and Habermann showed, in 1875, that when *gentianin* was melted with potassium hydroxide it yielded phloroglucin, $C_6H_3(OH)_3$, and dioxybenzoic acid, $C_6H_3.(OH)_2COOH$. The latter was at first called *gentianic* or *gentisinic acid*. Maisch believed that tannin is absent from gentian root, and states that the dark olive-green coloration observed when ferric chloride is added to its preparations is due to gentisic acid. (*A. J. P.*, 1876.) Ville (*A. J. P.*, 1877) and Davies (*P. J.*, 1879) maintain that there is a small quantity of tannin in gentian root. Patch (*A. J. P.*, 1876) found that an alcoholic solution of an ethereal extract of gentian yielded a dark-green coloration with ferric salts, but if the alcoholic solution were diluted with water it yielded no precipitate with gelatin. Subsequently (*Proc. A. Ph. A.*, 1881) he showed that there was a principle associated with the resinous matter in gentian (but which was not isolated in a state of purity) that produced the reactions of a tannin, viz., a greenish-black color with ferric chloride, and precipitates with tartar emetic, cinchonidine sulphate, and gelatin. Louis Magnes found in the root, when perfectly dried at 100° C. (212° F.), 15 per cent. of glucose. When gentian is macerated in cold water, it undergoes the vinous fermentation, in consequence of the presence of this saccharine principle. From the fermented infusion a spirituous liquor is obtained by distillation, which, though bitter, and having an unpleasant odor, is said to be relished by the Swiss and Tyrolese. A. Meyer (*Ph. Cb.*, May, 1882) obtained a sweet principle, which he called *gentianose*, $C_{18}H_{32}O_{31}$, by precipitation of the filtered juice with alcohol, treatment with ether, and crystallization from alcohol. It does not reduce Fehling's solution. Infusion of gentian is precipitated by tannic acid and the soluble salts of lead, but is compatible with the salts of iron. Pectin, so frequently found in fleshy roots, exists in gentian. (Bourquelot and Herissey, *Répert de Pharm.*, 1898.) The yellow coloring matter of the root was investigated by E. V. Howell, who concludes that it is quercitrin. Tanret (*P. J.*, lxxvi, p. 87) found two glucosides, *gentiamarin* and *gentiin*. He also states (*B. G. T.*, 1905, p. 730) that in fresh roots the amount of gentiopicrin is about 1.5 per cent., but that it is destroyed in the process of drying so that dried roots contain only 0.1 per cent.

Uses.—Gentian has been known from the highest antiquity and is said to have derived its name from Gentius, a king of Illyria. Many of the complex preparations handed down from the Greeks and Arabians contain it among their ingredients. The ordinary preparations of gentian are, however, almost without physiological properties except their local effects on the mucous membrane of the alimentary tract. Moorhead (*J. P. Ex. T.*, 1915, vii) has given a scientific rationale for the ancient empirical belief in the bitters, by showing that gentian markedly increased the gastric secretions in cachectic dogs. As a stimulant to gastric digestion gentian is perhaps the most popular of all bitters in the treatment of *atonic dyspepsia, anorexia,* and similar complaints. In overdose it acts as a local irritant and may occasion nausea or vomiting. The porous property of the root causes it to expand with moisture and it has been employed as a substitute for the sponge tent to enlarge strictured passages. According to Tanret (*B. G. T.*, 1905, p. 730) gentiopicrin is highly poisonous to the plasmodium and in doses of twenty to thirty grains (1.3–2.0 Gm.) is a useful remedy in *malarial fevers;* it might be pointed out in this connection that it would require between four and five pounds of dried gentian root to produce one dose of gentiopicrin.

Dose, fifteen to thirty grains (1–2 Gm.).

GLUCOSUM. U. S., Br.

GLUCOSE Glucos. [Syrupy Glucose, Liquid Glucose]
(glū-cō′sŭm)

"A syrupy product obtained by the incomplete hydrolysis of starch, consisting chiefly of dextrose (d-glucose) [$C_6H_{12}O_6 = 180.10$] and dextrins." *U. S.* "Glucose is a mixture of dextrose and other analogous substances, and is obtained by the hydrolysis of starch." *Br.*

Saccharum amylaceum; Saccharum uveum; Grape-sugar; Starch-sugar; Dextrose, *E.;* Stärkezucker; Traubenzucker; Kartoffelzucker, Glukose, Glykose, *G.*

Glucose was introduced into the U. S. P. IX and British Pharm., 1914, for the first time.

Glucose and syrupy glucose are commercial designations of the liquid or semi-solid product of the hydrolysis of starch by diluted acids in the presence of moisture and heat. Formerly the conversion was accomplished by the use of sulphuric acid, the excess of which was subsequently removed by neutralization with milk of lime and crystallizing out the difficultly soluble calcium sul-

phate, enough of which remained in solution, however, to render the detection of glucose in honey or cane sugar syrup indirectly possible by testing for calcium sulphate. (For details, see *U. S. D.*, 19th ed., p. 1071.) The conversion at the present time is accomplished by the use of hydrochloric acid which is ultimately volatilized by raising the temperature in open vessels, so that modern glucose contains no calcium sulphate and the older tests for its detection therefore are not applicable. The straw or amber color of the crude product was formerly removed by bleaching with sulphur dioxide, which sometimes was allowed to remain in the finished product in appreciable amounts. As many state food laws specifically prohibit sulphur dioxide or sulphites in most food products in which glucose was largely used as an ingredient, the modern method of decolorizing it is analogous to that for cane sugar and consists in the use of animal charcoal filters. The composition of commercial glucose varies. Theoretically the reaction is as follows:

$$\underset{\text{Starch}}{C_6H_{10}O_5} + H_2O = \underset{\text{Dextrose}}{C_6H_{12}O_6}.$$

In practice, however, the reaction is much more complex when a syrupy liquid is desired as is the case in commercial glucose and besides the dextrose which is the predominating constituent, maltose, and dextrin, which is the constituent that prevents glucose from crystallizing. Another carbohydrate, which is unfermentable, named *gallisin*, $C_{12}H_{24}O_{10}$, is also present in varying amounts.

Syrupy glucose is also known commercially as *corn syrup*, although a better name would be *starch syrup*, as it is only in the United States where corn is the cheapest raw material that it is made exclusively from corn starch. In Germany it is made from potato starch and it certainly would not be proper to term such a product "corn syrup."

On account of the preponderance of dextrose which is a powerful reducing sugar and directly capable of alcoholic fermentation glucose is much used in the industries where these properties are desirable as in brewing and in reducing indigo to its leuco derivative, indigo-white, in the dye vat. It is extensively used as an adulterant in dyewood extracts, sole leather, etc. It is a frequent ingredient in the manufacture of confectionary, jellies, etc. Formerly some discredit attached to its use in food products under the mistaken popular belief that its manufacture was in some way connected with that of glue. The question of its healthfulness is no longer in doubt for when properly made and free from impurities it may be considered as predigested starch.

It is theoretically possible, but not practicable at present, to make glucose not only from starch but also from any carbohydrate having the same formula, as cellulose (saw-dust).

The product of the complete hydrolysis or conversion of the starch by acids is commercially produced as a white or nearly white crystalline or waxy solid known as "*grape sugar*" or "*bread sugar*," the former name being applied because dextrose is also found in grapes and the latter name because it is used in bread baking on the large scale as a yeast food. It is also sometimes known as "*corn sugar*."

Glucose is not so sweet as cane sugar and is more slowly soluble in cold water.

Pure dextrose, $C_6H_{12}O_6$, which is sometimes improperly called glucose in chemical literature, may be obtained from commercial grape sugar by recrystallization and is in use as an ingredient in culture media in bacteriological work. It usually occurs in a hydrated form, $C_6H_{12}O_6 + H_2O$, and is in colorless crystals of a less sweet taste than sucrose, soluble in from 1 to 2 parts of cold water. It melts at 146° C. (294.8° F.), and at higher temperatures decomposes with the production of caramel. It is very strongly dextrorotatory from which fact it takes the name of dextrose. Nitric acid oxidizes it and forms a number of decomposition products of which *saccharic acid*, $H_2C_6H_8O_8$, is the most important. Saccharic acid is an amorphous, deliquescent solid easily soluble in water and forming salts with metallic bases.

Dextrose has strong reducing properties and is estimated quantitatively by means of Fehling's solution.

Glucose is officially described as follows: "A colorless or slightly colored, thick, syrupy liquid. It is odorless or nearly so and has a sweet taste. It is very soluble in water, sparingly soluble in alcohol. An aqueous solution of Glucose is neutral or slightly acid to litmus. Add a few drops of an aqueous solution of Glucose (1 in 20) to 5 mils of hot alkaline cupric tartrate T.S.; a copious red precipitate of cuprous oxide is produced (*distinction from cane sugar*). Introduce about 0.5 Gm. of Glucose into a wide-mouthed, tared weighing-bottle, weigh accurately, add 2 mils of distilled water, evaporate the water at about 70° C. (158° F.), and dry the residue to constant weight at 90° C. (194° F.). The loss in weight of the Glucose does not exceed 21 per cent. (*water*). Incinerate Glucose at a temperature not exceeding a low red heat; not more than 1 per cent. of ash remains. A solution of 5 Gm. of Glucose in 15 mils of distilled water, mixed with 5 drops of phenolphthalein T.S., requires not more than 0.6 mil of tenth-normal potassium hydroxide V.S. to produce a pink color (*free acid*). Dissolve about 2 Gm. of Glucose in 50 mils of distilled water, boil the solution for one minute and cool; the addition of one drop of tenth-normal iodine V.S. to this solution produces no blue color (*starch*). On now adding a few drops of starch T.S. to the solution a blue color is produced (*limit of sulphur dioxide*). An aqueous solution of Glucose does not respond to the Test for heavy metals (see Part III, Test No. 3). If the solution of Glucose is not colorless, comparison must be made with 10 mils of the same solution, to which a volume of distilled water, equal to that of the hydrogen sulphide T.S., has been added. Dissolve 1.5 Gm. of Glucose in 5 mils of distilled water; add 5

mils of diluted sulphuric acid and 1 mil of bromine water and heat for five minutes on a water bath. Then add 0.5 Gm. of potassium iodide, follow it with 5 drops of stannous chloride T.S., cool and subject the solution to the Test for arsenic (see Part III, Test No. 1). The stain produced, if any, is not greater than that produced in a test made with the same quantities of the reagents to which 2 mils of the standard arsenic test solution (see Part III, Test No. 1) has been added." *U. S.*

"A very viscous syrup, almost colorless. No odor; taste sweetish. Freely soluble in *water,* the solution being dextrorotatory and yielding a red precipitate when warmed with *solution of potassio-cupric tartrate.* 2 grammes dried at 100° C. (212° F.) in a thin film in a flat-bottomed dish do not lose more than 0.4 gramme (limit of moisture). When 10 grammes are dissolved in 100 millilitres of *water,* to which 10 millilitres of *N/10 solution of iodine* have previously been added, on shaking the mixture and immediately titrating with *N/10 solution of sodium thiosulphate,* not less than 6.8 millilitres of the latter solution are required for decolorisation (limit of sulphites). *Arsenic limit* 2 parts per million. Ash not more than 0.5 per cent." *Br.*

Uses.—As pointed out in the article on *saccharum* it is generally believed that the sugars must be converted into glucose before they are utilized by the body cells. At any rate it seems to be well established that glucose may be directly oxidized in the body and furnish energy to the various tissues. Thus Dixon (*J. P.,* 1907, xxxv, p. 346) has found that the injection of glucose into the blood stream may cause an immediate increase in the force of the cardiac contractions presumably by furnishing an easily oxidizable food stuff. In cases of severe malnutrition glucose may be used either hypodermically or intravenously to furnish an immediate fuel material to the body. For this purpose it is employed in the strengths of from one to five per cent. dissolved in physiological salt solution; one quart (1 liter) of the solution may be injected either directly into the vein or into the subcutaneous tissues. In cases of *gastric ulcer* or other conditions in which it is undesirable to administer food by the stomach, rectal enemata of six to eight fluidounces (180–240 mils) of a ten per cent. solution of glucose, every four hours, is often of assistance in aiding the maintenance of the nutritive condition. In *acidosis,* especially that type seen after prolonged *anesthesia,* the administration of large amounts of carbohydrates usually exercise a most beneficial action. The administration of glucose immediately before the production of anesthesia has been highly recommended as a preventative for vomiting, especially in children. (See *B. M. J.,* 1911, ii, p. 505.)

Locally glucose has been used for its dehydrating effect, especially in the treatment of gun-shot wounds. For this purpose gauze may be saturated with solutions of glucose, either with or without the addition of some antiseptic, and placed over the wounds. It is claimed that this treatment encourages the flow of lymph and thereby tends to diminish the severity of infection. (See *L. L.,* 1915, i, p. 851.) Pharmaceutically glucose is used in solid extracts and other preparations where a uniform, moist consistence is desired and as a diluent.

Off. Prep.—Used in making extracts U. S. P. and N. R., and in Br. Pharm. for pill masses. Ferri Carbonas Saccharatus, *Br.;* Ferri Phosphas Saccharatus, *Br.;* Mistura Ferri Composita, *Br.;* Syrupus Ferri Iodidi, *Br.;* Syrupus Glucosi, *Br.*

GLYCERINUM. U. S., Br.

GLYCERIN Glycerin. [Glycerol]

(glĭç-ĕ-rĭn'nŭm)

"A liquid obtained by the hydrolysis of vegetable or animal fats, or fixed oils, purified by distillation, and containing not less than 95 per cent. of the trihydric alcohol $C_3H_5(OH)_3$ or $CH_2OH.CHOH.CH_2OH$ (92.06). Preserve it in well-closed containers." *U. S.* "Glycerin, or glycerol, is a trihydric alcohol, $C_3H_5(OH)_3$, associated with a small percentage of water; it is obtained by the hydrolysis of fats and fixed oils by means of alkalies or of superheated steam." *Br.*

Glycerina, *U. S.* 1870; Glycerine; Glycerine officinale, *Fr. Cod.;* Glycerinum, *P. G.;* Glycerin, Glyceryloxyhydrat, Oelsüss, Scheelesches Süss, *G.;* Glicerina, *It., Sp.*

Litharge, olive oil, and water are boiled together in the 1890 process for making lead plaster; the olein of the oil is decomposed by the lead oxide, according to the following reaction:

$$2(C_3H_5(OC_{18}H_{33}O)_3) + 3PbO + 3H_2O = 2(C_3H_5(OH)_3) + 3(Pb(OC_{18}H_{33}O)_2)$$

by which lead oleate or plaster and free glycerin are obtained. (See *Emplastrum Plumbi.*) It follows, therefore, that the plaster, while still hot and in the liquid state, contained glycerin diffused through it. It was this process that was used for preparing glycerin in the formula of U. S. P., 1850. In accordance with this, when the liquid plaster is mixed with an equal measure of boiling water, and the mixture stirred briskly, a solution of glycerin is obtained, which, after having been decanted, and evaporated to a limited extent, is freed from lead by hydrogen sulphide. The liquid is then filtered to separate lead sulphide, heated to free it from hydrogen sulphide, and finally evaporated to expel the water, which is known to be all removed when the mass ceases to lose weight.

Glycerin was discovered in 1789 by Scheele, by whom it was called the *sweet principle of oils.* It is produced not only during the saponification of the fats and oils by lead oxide in forming lead plaster, but also during the same process when effected by potassium and sodium hydroxides in the manufacture of soap, the alkalies uniting with the fatty acids and setting the glycerin free. Soap-maker's waste is an abundant source of glycerin; but when thus obtained it is apt to have more or less odor, which even

percolation through animal charcoal does not always remove. The recovery of glycerin from spent soap lyes is effected very generally by the Van Ruymbeke process. The lye is settled and drawn off from the sludge, treated with a "persulphate of iron" containing about 50 per cent. of sulphuric acid, which forms a copious precipitate of ferric hydroxide and iron soaps and carries down all other insoluble impurities. After filtration, the lye, which is nearly water-white, is evaporated in vacuo. Some sodium sulphate and sodium chloride crystallize out, after which the glycerin is concentrated and distilled under a high vacuum. The two methods of saponification by which glycerin has been obtained on a large scale are the process of Wilson and Payne, of decomposing the fats by superheated steam and subsequent distillation, and the lime autoclave process of Milly. The process of Richard A. Tilghman, of Philadelphia (the patent for which was obtained in 1854, and, after years of litigation, was at last sustained in 1888), consists in subjecting fatty bodies to the action of water at a high temperature under pressure, whereby the fats, which are *glycerides* or *esters* of the fatty acids, are broken up into free glycerin and free fatty acids, the water supplying the elements of hydrogen and oxygen necessary for that change. The reaction is as follows for the case of a fat like stearin:

$$C_3H_5(OC_{18}H_{35}O)_3 + 3H.OH = C_3H_5(OH)_3 + 3C_{18}H_{35}O.OH$$

More recent processes are the hydrolysis of fats in the presence of the Twitchell reagents (a sulphonated fatty acid), and the Connstein ferment process. The former especially is now in general use in all modern soap factories. Ordinary impure glycerin may be purified by distillation with steam under pressure. Though, when distilled alone, it is partially decomposed, giving off pungent vapors of *acrolein*, yet in a current of superheated steam it passes over unchanged at temperatures between 204.4° and 260° C. (400° and 500° F.). A better grade of glycerin made by distillation is known as *dynamite glycerin*. A still purer product is made by maintaining it at 0° C. (32° F.) for some time and then inducing crystallization by introducing a few crystals previously prepared by cooling to a much lower temperature. It crystallizes in large massive crystals of a high degree of purity. Glycerin is now being made by synthetic processes. A recent English patent starts with propylene which is first converted into dichlor-propane, which subsequently is converted into allyl chloride and then into trichlor-propane, $CH_2Cl.CHCl.CH_2Cl$, which when heated with water to 150° C. (302° F.) splits up into glycerin and water according to the following reaction:

$$\underset{\text{Trichlor propane}}{CH_2Cl.CHCl.CH_2Cl} + 3H_2O = \underset{\text{Glycerin}}{CH_2OH.CHOH.CH_2OH} + 3HCl.$$

Glycerin is always produced to a limited extent during alcoholic fermentation, the amount of glycerin present in certain liquids produced originally by alcoholic fermentation as wine, vinegar, etc., being so constant as to constitute a valuable aid in proving identification or freedom from adulteration. Various attempts have been made to economically recover the glycerin from the waste liquors of distilleries but without practical results as yet, although there is little doubt of its ultimate accomplishment. In 1909 the United States production of glycerin was given as 81,885,536 pounds, and the present production is estimated to be 100,000,000 pounds.

Properties.—"Glycerin is a clear, colorless liquid, of a thick, syrupy consistence, having not more than a slight, characteristic odor which is neither harsh nor disagreeable, sweet to the taste and producing a sensation of warmth in the mouth; when exposed to the air, it absorbs moisture. Glycerin is miscible with water or alcohol; insoluble in chloroform, ether, benzene, petroleum benzin, carbon disulphide or fixed or volatile oils. An aqueous solution of Glycerin (1 in 20) is neutral to litmus. Specific gravity: not below 1.249 at 25° C. (77° F.). Glycerin does not appreciably volatilize from weak aqueous solutions. When of a strength between 70 and 100 per cent., it rapidly volatilizes at 100° C. (212° F.). Heat a few drops of Glycerin with about 0.5 Gm. of potassium bisulphate; pungent vapors of acrolein are evolved. Glycerin is colorless when viewed transversely in a tube of colorless glass about 30 mm. in diameter, held in a vertical position. Heat 50 Gm. of Glycerin in an open, shallow, 100 mil porcelain or platinum dish until it ignites, then allow it to burn without further application of heat in a place free from draught; not more than 0.015 per cent. of carbonaceous and mineral residue remains. Subject this residue to a low red heat, until combustion is complete; not more than 0.007 per cent. of mineral ash remains. This ash, when dissolved in 10 mils of distilled water and titrated with hundredth-normal silver nitrate V.S., using potassium chromate T.S. as indicator, shows, in the original 50 Gm. of Glycerin, not more than 0.001 per cent. of chlorides calculated as sodium chloride. Each mil of hundredth-normal silver nitrate V.S. consumed corresponds to 0.0005846 Gm. of NaCl. Mix 5 mils of Glycerin by vigorous shaking with an equal volume of sulphuric acid in a glass-stoppered cylinder; the liquid does not become darker than yellow on standing for one hour (*readily carbonizable impurities*). Mix 50 Gm. of Glycerin with 50 mils of freshly boiled distilled water and 5 mils of half-normal potassium hydroxide V.S., and boil the mixture for five minutes. When cold, it requires not less than 4 mils of half-normal hydrochloric acid V.S. for neutralization, using phenolphthalein T.S. as indicator (*fatty acids and esters*). An aqueous solution of Glycerin (1 in 10) remains clear on the addition of calcium chloride T.S. (*oxalic acid*); another portion of

the solution is not affected by barium chloride T.S. after acidulation with a few drops of diluted hydrochloric acid (*sulphate*). An aqueous solution of Glycerin does not respond to the Test for heavy metals (see Part III, Test No. 3). An aqueous solution of Glycerin meets the requirements of the Test for arsenic (see Part III, Test No. 1). A mixture of 5 mils of Glycerin and 5 mils of an aqueous solution of potassium hydroxide (1 in 10) does not become yellow when kept for five minutes at 60° C. (140° F.) (*acrolein, glucose*), nor emit an odor of ammonia (*ammonium compounds*)." *U. S.*

"A clear, colorless, hygroscopic, syrupy liquid. No odor; taste sweet, followed by a sensation of warmth. Miscible with *water,* and with *alcohol* (90 per cent.). Insoluble in *ether,* in *chloroform,* and in fixed oils. Specific gravity 1.260. When strongly heated decomposes with evolution of irritating vapors. Neutral to *litmus.* An aqueous solution (1 in 10) yields no characteristic *reactions* for ammonium, chlorides, or sulphates. Assumes, when heated, not more than a faint yellow but no pink coloration, and yields not more than a very slight charred residue and no odor of burnt sugar (absence of sugar). Undergoes no darkening in color when mixed with an equal volume of *solution of ammonia* and a few drops of *solution of silver nitrate,* the mixture being kept protected from light and the observation being made after a lapse of five minutes (absence of formic acid, acrolein). Gently warmed with an equal volume of *diluted sulphuric acid,* the mixture being vigorously shaken, not more than a faint odor is noticeable (absence of fatty acids). Shaken with an equal volume of *sulphuric acid,* the mixture being kept cool, not more than a very slight straw coloration is produced (absence of extraneous organic matter). A mixture of 10 millilitres of Glycerin with 40 millilitres of *water,* 1 drop of *solution of ammonia,* and 1 drop of *solution of tannic acid,* assumes not more than a faint and transient pink or purple coloration (limit of iron). When tested for lead according to the quantitative test described in Appendix V, but using 10 grammes in each Nessler glass, no difference is observed upon the addition of the *solution of sodium sulphide* to one of the solutions (absence of lead). When the foregoing test is repeated, but omitting the addition of *solution of ammonia* and of *solution of potassium cyanide,* and adding to each solution 1 millilitre of *diluted hydrochloric acid,* no difference in color is observed upon the addition of *solution of hydrogen sulphide* to one of the solutions (absence of copper). *Arsenic limit* 4 parts per million. No appreciable ash." *Br.*

When exposed to the air glycerin gradually absorbs moisture. As already stated, though decomposed by a high heat in its unmixed state, yet with water under pressure it is volatilizable unchanged at a temperature between 204.4° and 260° C. (400° and 500° F.). Cooled down rapidly, it only becomes more viscid, without congealing, even when a temperature of –40° C. (–40° F.) is attained; but, if kept for some time at a temperature of about 0° C. (32° F.), it gradually forms hard but deliquescent crystals, which melt only at about 22° C. (71.6° F.). This fact is now utilized as a means of concentrating and purifying glycerin. According to G. F. Wilson, glycerin, when of the density 1.24, contains 94 per cent. of anhydrous glycerin; when of the density 1.26, 98 per cent. A table by Wilhelm Lenz (*Zeit. An. Chem.,* 1880), showing the percentage of absolute glycerin in mixtures of glycerin and water, which was obtained by a quantitative determination of the carbon in the various dilutions by ultimate analysis, will be found in the U. S. D., 15th ed., p. 712. The table below by W. W. J. Nicol of England, has been constructed after careful determinations, aided by A. B. Lyons's data on expansion of glycerin solutions. (*Ph. Era.,* 1888.)

Glycerin has been formed artificially from

tribromallyl, by Wurtz, and from trichlorhydrin, by Friedel and Silva.

Glycerin possesses extensive powers as a solvent, and is an excellent excipient for many medicinal substances. It dissolves bromine and iodine, sulphur iodide, potassium and sodium chlorides, the fixed alkalies, some of the alkaline earths, lime, for example, for which it increases the solvent powers of water (*J. P. C.*, June, 1874), and a large number of neutral salts. It also dissolves the vegetable acids, particularly tannic acid. It is a good solvent of pepsin, and is used for the extraction of this principle from the mucus of the stomach. Two parts and a half of glycerin dissolve one of sugar, and three and a half parts, one of gum. When starch paste and glycerin are heated together, a turbid liquid is formed, which deposits on cooling, the supernatant liquid holding starch in solution. (*J. P. C.*, Nov., 1868, pp. 361–362.) J. S. Blockley of London, has ascertained that certain glucosides are far more soluble in glycerin than in water. Thus, salicin dissolves in eight parts of cold glycerin, and santonin in eighteen parts when boiling. The latter solution, when of half this strength, forms on cooling an almost solid mass. Glycerin, next to alcohol, is the best solvent of iodine. Iodine and potassium iodide, when dissolved in it, form *iodized glycerin*, the medicinal applications of which are given under iodine. (See *Iodum.*) It combines with a number of alkalies, and also with sulphuric acid. Glycerin does not evaporate rapidly when exposed to the air, although it vaporizes to such an extent as to make it necessary to avoid a water-bath temperature to the concentrated article during its quantitative estimation. It can not be distilled without decomposition, unless in the presence of water or steam. When decomposed by heat, it emits extremely irritating vapors of acrolein, which is allylaldehyde, $CH_2.CH.CHO$. At a full red heat it takes fire, and burns with a blue flame. In consequence of the high temperature required for its volatilization, it has been proposed to use it for an evaporating bath, in which a heat beyond that of boiling water is required. Glycerin is antiseptic, and has been recommended by Warington and Demarquay to preserve alimentary substances and objects of natural history, and to inject bodies for dissection. According to W. Frazer, it does not answer for preserving pathological preparations, as they are completely softened by its action. Berthelot of Paris, succeeded in combining glycerin with a number of acids, both mineral and organic, forming three distinct series of neutral compounds. Among others, he has united it with the fatty acids, producing, by synthesis, the organic fatty substances stearin, palmitin, olein, etc.

By Pasteur it was ascertained to be one of the products of the vinous fermentation. Glycerin is a triatomic alcohol, being a compound of the triad radical (C_3H_5) with 3(OH) groups. In the natural fats, the three H atoms of these OH groups are replaced by fatty acid radicals like stearyl, $C_{18}H_{35}O$, palmityl, $C_{16}H_{33}O$, and oleyl, $C_{18}H_{33}O$. The natural fats are, therefore, compounds of an alcohol radical with an organic acid, and are true esters, which are known as *glycerides*.

The solvent and preservative properties as well as agreeable taste and permanent consistence of glycerin render it very useful as a menstruum in pharmacy, and a class of preparations consisting of medicinal substances dissolved in it has come into extensive use. The British Pharm. (1885) adopted such a class, under the name of *Glycerina*, or *glycerins*. The title "glycerines" is not now available because the termination "ine" is reserved for alkaloids, while the term *glyceroles*, adopted from the French, is objectionable, as the termination "ole" has been used to designate certain proximate principles; but the U. S. Pharmacopœia title, *Glycerita*, or *glycerites*, is satisfactory. (See *Glycerita*, p. 523.) G. M. Beringer proposed a class of preparations made with glycerin. (See *Fluidglycerates*, in the National Formulary IV.)

Impurities and Tests.—Glycerin is occasionally deficient in density and consistency. According to Dalpiaz, it is sometimes perfectly colorless from being bleached by chlorine, when it is apt to contain calcium chloride, as well as free chlorine. The latter may be detected by rendering the suspected sample slightly blue by a few drops of an acid solution of indigo in sulphuric acid, when, if free chlorine be present the blue color will disappear. Starch paste containing a little potassium iodide is a better test, however; if a blue color appears when this is added to glycerin, free chlorine is indicated. (See U. S. P. and Br. tests, page 519.)

Glycerin, on account of its high price (1917), has been substituted industrially by a number of cheaper products, among which was a commercial invert sugar of about the same consistency as glycerin, but slightly higher in specific gravity. (Jos. Feil, *J. A. Ph. A.*, 1914, 1648.)

In the quantitative determination of glycerin when in a state of purity, the specific gravity test is important. In crude glycerin and in other products where it may only exist in small amounts, various processes are in use. One of the best known of these is the Hehner, Richardson, Jaffe, method, which depends upon the oxidation of potassium dichromate, or it may be determined by its acetylization with acetic anhydride, the so-called acetin method.

The official method of the A. O. A. C. given in Bulletin No. 107, of the Bureau of Chemistry of the U. S. Department of Agriculture, is used for the determination of glycerin in wines, etc. Leroy Forman (*J. A. Ph. A.*, 1914, 1644) shows this method to give low results when applied to the analysis of tablets, confections, etc. He overcomes this difficulty by the use of milk of lime during the evaporation.

For a method of extracting glycerin from mixtures containing sugar and glucose, see a paper by Prescott, *N. R.*, 1878. For methods of determining glycerin in mixtures or its detection in wines, etc., see *Chem. News*, 1882; *A. J. P.*, 1882; *S. W. P.*, 1881; *Chem. News*, 1886; *Am. Drug.*, 1886.

Uses.—Glycerin is valuable as a vehicle not only because of the solvent properties noted on page 521, but because of its sweetness, having the great advantage over syrup of non-fermentability. It has been recommended as a preservative for galenicals in which alcohol is undesirable, but its antiseptic action is so slight that its usefulness for this purpose is very questionable. When injected intravenously in large doses it is capable of causing severe and even fatal poisoning, but the amount required to produce this effect is so large as to suggest that it acts rather by altering the physical condition of the blood than by any true physiological properties. It is absorbable from the alimentary tract and although partly eliminated unchanged, a portion seems to be oxidized in the body and is apparently capable of furnishing energy to the system. (See Catillon, *A. G. P.*, 1889–1890, xlvi.) It is, however, of no practical value as a food-stuff and although it was at one time suggested as a substitute for cod liver oil in *phthisis* it has been shown to be worthless. Faust and Tallquist (*A. E. P. P.*, 1907, lvii, p. 366), on the theory that the hemolytic poison in *pernicious anemia* is oleic acid, suggested the use of glycerin as a remedy and the theory has received some clinical confirmation. As a local application glycerin is often of service. Many believe that beneficial effects of the cataplasm of kaolin are largely due to the glycerin it contains, and pure glycerin has been recommended as an application in *burns, wounds, furuncles,* and similar local inflammatory diseases. Its beneficial effects in these conditions are commonly attributed to its hygroscopic properties. In a diluted form it is often of great value for its emollient properties in various forms of *skin diseases;* pure glycerin may irritate a delicate skin.

It has recently been extensively employed in habitual *constipation* in the form of suppositories. (See *Suppositoria Glycerini.*)

To collodion it gives a valuable plasticity. Incorporated in very small proportion with extracts and pills, it keeps them soft and free from mouldiness. Glycerin may be used in the form of an ointment, and is also used in the menstruum of official extracts, fluidextracts, glycerites, infusions, syrups, tinctures, etc., and in making pills.

Dose, one fluidrachm (3.75 mils).

Off. Prep.—Gelatinum Glycerinatum, *U. S.;* Suppositoria Glycerini, *U. S., Br.;* Cataplasma Kaolini, *N. F.;* Glycerites, *U. S.* (*Br.*), Fluidextracts, *U. S., N. F.;* Tinctures, *U. S., N. F.;* and as solvent and preservative in other preparations; Glycerites, *N. F.;* Fluidglycerates, *N. F.*

GLYCERINUM ALUMINIS. Br.

GLYCERIN OF ALUM

(glĭç-ẹ-rī′nŭm ạ-lū′mĭ-nĭs)

Glycéré d'Alun, *Fr.;* Alaun-Glycerit, *G.*

"Purified Alum, 20.0 *grammes;* Distilled Water, 7.5 *millilitres;* Glycerin sufficient to produce 120.0 *millilitres.* Powder the Alum, triturate with the Distilled Water and Glycerin until solution is effected, warming slightly if necessary; set aside; pour off the clear liquid from any deposit that may be formed." *Br.*

This has an astringency similar to glycerite of tannin without the tendency to soil the linen or blacken in contact with iron, but it is much more irritating.

GLYCERINUM BORACIS. Br.

GLYCERIN OF BORAX

(glĭç-ẹ-rī′nŭm bọ-rā′cĭs)

Glycéré de Borax, *Fr.;* Borax-Glycerit, *G.*

"Purified Borax, 20 *grammes;* Glycerin, 120 *millilitres.* Powder the Borax, and triturate with the Glycerin in a warmed mortar until solution is effected." *Br.*

The demulcent properties and sweet taste of this preparation render it a useful and convenient method of applying borax to the infantile *thrush* and other forms of sore mouth in children. It has been highly commended in *erysipelas* by D. M. Salazar of Madrid. The part should be freely painted with it and then covered with raw cotton. (*N. Y. M. R.*, viii 311.)

GLYCERINUM PEPSINI. Br.

GLYCERIN OF PEPSIN

(glĭç-ẹ-rī′nŭm pĕp-sī′nī)

Glycéré de Pepsine, *Fr.;* Pepsin-Glycerit, *G.*

"Pepsin, 100.0 *grammes;* Hydrochloric Acid, 11.5 *millilitres;* Glycerin, 600.0 *millilitres;* Distilled Water, sufficient to produce 1000.0 *millilitres.* Mix the Hydrochloric Acid, Glycerin, and two hundred and sixty *millilitres* of the Distilled Water; add the Pepsin; dissolve; add sufficient Distilled Water to produce the required volume; set aside for twenty minutes; filter. Ten mils of this preparation contain 1 gramme of Pepsin; 1 fluidrachm contains about 5.5 grains." *Br.*

This preparation is practically identical with the glycerite of pepsin of the National Formulary. (See Part III.)

Dose, one fluidrachm (3.75 mils), equivalent to five grains of pepsin.

GLYCERINUM PLUMBI SUBACETATIS. Br.

GLYCERIN OF SUBACETATE OF LEAD

(glĭç-ẹ-rī′nŭm plŭm′bī sŭb-ăç-ẹ-tā′tĭs)

Glycéré de Sousacétate de Plomb, *Fr.;* Bleiessigglycerit, *G.*

"Strong Solution of Lead Subacetate, 500 *millilitres;* Glycerin, 500 *millilitres;* Distilled

Water, a sufficient quantity. Evaporate the Strong Solution of Lead Subacetate to dryness on a water-bath; add the Glycerin; warm gently until dissolved; cool; add Distilled Water till the specific gravity of the mixture is 1.48; filter, if necessary." *Br.*

This glycerite originated with Balmanno Squire of London, but the process made official in the Br. Pharm. (1898) was that recommended by R. W. Parker. (See *A. J. P.*, 1886, 296.) The official process (1914) is a simpler one and more convenient for the pharmacist. It is a powerful sedative astringent, and may be employed as a local application in external inflammation.

GLYCERINUM TRAGACANTHÆ. Br.

GLYCERIN OF TRAGACANTH

(glĭç-ĕ-rĭ'nŭm trăg-ă-căn'thæ)

Glycéré de Gomme Adragante, *Fr.;* Traganth-Glycerit, *G.*

"Tragacanth, in powder, 10 *grammes;* Glycerin, 30 *millilitres;* Distilled Water, 10 *millilitres.* Mix the Glycerin with the Tragacanth; add the Distilled Water; triturate until a homogeneous paste is produced." *Br.*

This preparation has been introduced into the British Pharmacopœia mainly to serve as an excipient for pills.

GLYCERITA

GLYCERITES

(glĭç-ĕ-rĭ'tă)

Glycerinum, *Br.;* Glycerins; Glycerata, Glycerolata, Glycerols; Glycérés, *Fr. Cod.;* Glycérats, Glycérolés, *Fr.;* Glycerit, Glycerolat, *G.*

These are solutions of medicinal substances in glycerin. In the thirteenth edition of the Dispensatory various reasons were adduced for preferring the name glycerates for these preparations, but, as the revisers of the U. S. Pharmacopœia have adopted that of glycerites, these reasons are omitted. The U. S. name is certainly much better than the British name glycerin (*Glycerinum*) for this does not distinguish a *class* of preparations from the *solvent* used in making them. (See preceding articles.)

Glycerin has valuable properties as a solvent and vehicle for medicinal substances. Such are its not unpleasant taste and bland character, its wide range of solvent power, which adapts it sometimes as a menstruum where neither water nor alcohol could be advantageously used, and enables it to retain in solution otherwise insoluble substances so frequently found in infusions and decoctions, and its preservative influence, which often protects against oxidation, and, by a destructive agency upon all of the lowest forms of vegetable and animal life, prevents the various fermentative processes so destructive to organic bodies. Another important property, as a vehicle for external remedies, is the permanence of its liquid character, so that it does not, like water and alcohol, dry up when applied to the skin, resembling in this respect, as well as in its demulcent quality, the fixed oils, without their tendency to rancidity. Hence it has of late come into extensive use in the preparation of medicinal solutions, which, under the name of *Glycérés* found admission into the French Codex of 1866, and are now recognized by both the United States and British Pharmacopœias.

GLYCERITUM ACIDI TANNICI. U. S. (Br.)

GLYCERITE OF TANNIC ACID Glycer. Acid. Tann. [Glycerite of Tannin]

(glĭç-ĕ-rĭ'tŭm ăç'ĭ-dī tăn'nĭ-cī)

Glycerinum Acidi Tannici, *Br.;* Glycerin of Tannic Acid (of Tannin); Glycéré de Tannin, *Fr. Cod.;* Glycérole de Tannin, Glycérine tannique, *Fr.;* Tannin-Glycerit, Tannin-Glycerol, *G.*

* "Tannic Acid, *twenty grammes* [or 308.6 grains]; Glycerin, *eighty grammes* [or 2 ounces av., 360 grains], to make *one hundred grammes* [or 3 ounces av., 231 grains]. Weigh the glycerin into a tared, wide-mouthed bottle with a capacity of about *one hundred and twenty-five mils.* Place the bottle and contents in a water bath, heat the water until it boils, and continue the heat for a few minutes; add the tannic acid to the hot glycerin in small, successive portions, agitate the mixture until the tannic acid is dissolved and strain the solution while warm through purified cotton." *U. S.*

"Tannic Acid, 20 *grammes;* Glycerin, sufficient to produce 100 *millilitres.* Triturate the Tannic Acid with the Glycerin in a warmed mortar until solution is effected." *Br.*

The U. S. preparation is a 20 per cent. solution by weight; the strength of the British preparation is somewhat weaker, being a 20 per cent. solution by measure. H. F. Meier found that the greenish scum usually seen on the surface of the preparation is chlorophyll from the tannin.

This preparation may be used, both internally and externally, for most of the purposes to which tannic acid is applied. On the whole, it is the most useful preparation of tannic acid for external use; as circumstances require it the official strength may be altered by direction of the physician; a very concentrated solution, two parts of glycerin to one of tannin, may be made by the aid of a moderate heat. This applied daily to nipples, during the later months of pregnancy, will usually prevent the occurrence of *sore nipples* during suckling.

Dose, from ten to forty minims (0.65–2.6 mil). (See *Acidum Tannicum.*)

GLYCERITUM AMYLI. U. S. (Br.)

GLYCERITE OF STARCH Glycer. Amyl.

(glĭç-ĕ-rĭ'tŭm ăm'y-lī)

Glycerinum Amyli, *Br.,* Glycerin of Starch, Glycamyl, Plasma; Glycéré d'Amidon, *Fr. Cod.;* Glycérate simple (d'Amidon), *Fr.;* Unguentum Glycerini, *P. G.;* Glycerinsalbe, Stärke-Glycerit, *G.;* Glicerolato di amido, *It.;* Glicerolado de almidon, *Sp.*

* "Starch, *ten grammes* [or 154 grains]; Water, *ten mils* [or 162 minims]; Glycerin,

eighty grammes [or 2 ounces av., 360 grains]. Triturate the starch with the water, until a homogeneous mixture is produced. Then gradually add this to the glycerin, contained in a porcelain dish, and heated to about 140° C. (284° F.). Continue the heat, with constant stirring, keeping it below 144° C. (291.2° F.), until a translucent jelly is formed. Transfer the product to suitable vessels, provided with well-fitting covers." *U. S.*

"Starch, 20 *grammes;* Glycerin, 130 *millilitres;* Distilled Water, 30 *millilitres.* Mix; heat, stirring constantly, until a translucent jelly is formed." *Br.*

Of these preparations it is only necessary to say that, with the exception of an inconsiderable difference in the proportions, they are the same as that brought into notice in 1858 by G. F. Schacht under the name of *plasma,* as a substitute for ointments, the emollient and demulcent properties of which they possess, without their inconvenience, whether used simply, or as a vehicle for other substances to be employed locally. Schacht prepared plasma by mixing 70 grains of starch in powder, and a fluidounce of glycerin, heating to 115.6° C. (240° F.) until the union is effected, and stirring constantly. The stirring should be continued moderately, during the cooling, to secure a proper consistence. As the plasma is liable to absorb moisture, it should be kept in well closed vessels. (*P. J.,* Oct., 1866, 210.) J. H. Pearson (*P. J.,* 1897, 201) recommends the addition of one grain of powdered tragacanth to the ounce of finished product, to prevent the separation of the glycerin and water from the mass, on standing.

GLYCERITUM BOROGLYCERINI. U. S. (Br.)

GLYCERITE OF BOROGLYCERIN Glycer. Boroglyc. [Solution of Boroglyceride]

(glĭç-ĕ-rī'tŭm bō-rō-glĭç-ĕ-rī'nī)

Glycerinum Acidi Borici, *Br.;* Glycerin of Boric Acid; Glycerite of Glyceryl Borate; Glycéré de boroglycéride, *Fr.* Boroglyceridlösung, *G.*

* "Boric Acid, in fine powder, *three hundred and ten grammes* [or 10 ounces av., 409 grains]; Glycerin, *a sufficient quantity,* to make *one thousand grammes* [or 35 ounces av., 120 grains]. Heat *four hundred and sixty grammes* [or 16 ounces av., 99 grains] of Glycerin, in a tared porcelain dish on a sand bath, to a temperature between 140° and 150° C. (284° and 302° F.), and add the boric acid in portions, constantly stirring. When all is added and dissolved, continue the heat at the same temperature, frequently stirring, and breaking up the film which forms on the surface until the mixture has been reduced to the weight of *five hundred grammes* [or 17 ounces av., 279 grains] then add to it *five hundred grammes* [or 17 ounces av., 279 grains] of glycerin, mix thoroughly, and immediately transfer it to bottles and stopper them tightly." *U. S.*

"Boric Acid, 300 *grammes;* Glycerin, sufficient to produce 1000 *grammes.* Add the Boric Acid to four hundred and fifty *grammes* of the Glycerin, boil until dissolved, constantly stirring; evaporate at a temperature rising to but not exceeding 150° C. (302° F.) until the weight of the mixture has been reduced to five hundred grammes, the stirring being continued. Add sufficient Glycerin to produce the required weight; mix thoroughly." *Br.*

This solution was first introduced into the U. S. P. 1890 from the National Formulary. It is a thick, sweet, viscid, colorless liquid, and has the advantage of offering the antiseptic, boric acid, in a very soluble form. It may be made more rapidly than by the above process if one ounce av. of boroglyceride be dissolved in one ounce av. of glycerin with the aid of a gentle heat. (See *Boroglyceride,* Part II.)

GLYCERITUM HYDRASTIS. U. S.

GLYCERITE OF HYDRASTIS Glycer. Hydrast. [Glycerite of Goldeh Seal]

(glĭç-ĕ-rī'tŭm hȳ-drăs'tĭs)

"*One hundred mils* of Glycerite of Hydrastis yields not less than 1.12 Gm. nor more than 1.37 Gm. of the ether-soluble alkaloids of hydrastis." *U. S.*

Glycéréd'Hydrastis du Canada, *Fr.;* Gelbwurzel-Glycerit, *G.*

* "Hydrastis, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, Alcohol, Water, each, *a sufficient quantity,* to make about *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Moisten the Hydrastis with *three hundred and fifty mils* [or 11 fluidounces, 401 minims] of Alcohol, pack it firmly in a cylindrical percolator; and add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the drug is exhausted. Remove nearly all of the Alcohol, by distillation or evaporation, pour the thick concentrated liquid into *four hundred and fifty mils* [or 15 fluidounces, 104 minims] of ice-cold Water, and set it aside, in a cold place, for twenty-four hours. Then filter and assay a portion of this filtrate by the process given below, and, from the result thus obtained, ascertain by calculation the amount of ether-soluble alkaloids in the remainder of the liquid. Add to this enough cold water to make each *one hundred mils* of the product contain 2.5 Gm. of the ether-soluble alkaloids of hydrastis. Finally add an equal volume of glycerin, and mix." *U. S.*

"Assay.—Proceed as directed under *Fluidextractum Belladonnæ Radicis,* page 486, first line of the Assay, modifying the process there given by using 5 mils of Glycerite of Hydrastis instead of 10 mils of fluidextract of belladonna root and using only ether as the immiscible solvent throughout the assay. Wash the final ether extractions with 10 mils of distilled water, draw off the water and discard it. Then filter the ether solution through a pledget of purified cotton, wash the cotton with ether, evaporate

the filtrate and washings, and dry the residue at 100° C. (212° F.) to constant weight instead of titrating it. The weight represents the amount of ether-soluble alkaloids in 5 mils of the Glycerite of Hydrastis." *U. S.*

The process for this glycerite has been improved by adopting J. U. Lloyd's suggestion to concentrate the alcoholic tincture by distillation or evaporation and pouring the thick liquid into ice-cold water, for the purpose of separating the oily and resinous matter which is useless. F. A. Sieker found that glycerite of hydrastis as made by the former U. S. process varies greatly in strength. (See *Proc. A. Ph. A.*, 1893, 691; also *Ph. Rund.*, 1895, 236, and *Proc. A. Ph. A.*, 1894, 668.) Its medicinal properties are those of hydrastis.

Dose, from one-half to one fluidrachm (1.8–3.75 mils).

GLYCERITUM PHENOLIS. U. S. (Br.)

GLYCERITE OF PHENOL Glycer. Phenol. [Glyceritum Acidi Carbolici, Pharm. 1890, Glycerite of Carbolic Acid]

(glĭç-ẹ-rī'tŭm phẹn-ō'lĭs)

Glycerinum Acidi Carbolici, *Br.;* Glycerin of Phenol; Glycérole d'Acide Phénique, Glycéré de Phenol, Glycérine Phénique, *Fr.;* Phenol-Glycerit, *G.;* Glycerina con acido fenico, *Sp.*

* "Liquefied Phenol, *twenty mils* [or 325 minims]; Glycerin, *eighty mils* [or 2 fluidounces, 338 minims], to make *one hundred mils* [or 3 fluidounces, 183 minims]. Add the Liquefied Phenol to the Glycerin, and thoroughly mix." *U. S.*

"Phenol, 20 *grammes;* Glycerin, sufficient to produce 100 *millilitres.* Triturate the Phenol with the Glycerin in a warmed mortar until solution is effected." *Br.*

Uses.—For the uses of this preparation, see *Phenol.* The U. S. P. IX glycerite is a 20 per cent. by volume solution of liquefied phenol; the British preparation is slightly stronger, being a 20 per cent. by volume solution of crystallized phenol. It may be used internally or locally, and for both purposes should in general be diluted with water.

Dose, from five to ten minims (0.32–0.65 mil).

GLYCYRRHIZA. U. S. (Br.)

GLYCYRRHIZA Glycyrrh. [Licorice Root Licorice Liquorice Root]

(glĭç-ŷr-rhī'zạ)

"The dried rhizome and roots of *Glycyrrhiza glabra typica* Regel et Herder, known in commerce as Spanish Licorice, or of *Glycyrrhiza glabra glandulifera* Regel et Herder, known in commerce as Russian Licorice (Fam. *Leguminosæ*). Preserve powdered and whole Glycyrrhiza in tightly-closed containers to which a few drops of chloroform or carbon tetrachloride are added from time to time to prevent attack by insects." *U. S.* "Liquorice Root is the peeled root and peeled subterranean stem of Glycyrrhiza glabra, *Linn.*, and other species of Glycyrrhiza." *Br.*

Glycyrrhizæ Radix, *Br.;* Radix Glycyrrhizæ Hispanicæ, Spanish Licorice Root; Réglisse, *Fr. Cod.;* Racine de Réglisse, Bois doux, Racine douce, Bois de Réglisse, *Fr.;* Radix Liquiritiæ, *P. G.;* Spanisches Süssholz, Spanische Süssholzwurzel, Süssholzwurzel, *G.;* Liquirizia, *It.;* Regaliz (Raiz de), Orozuz, Palo dulce, *Sp.*

Glycyrrhiza glabra has a perennial root, which is round, succulent, tough, and pliable, furnished with sparse fibers, rapid in its growth, and in a sandy soil penetrates deeply into the ground. The stems are herbaceous, erect, slightly branching, and usually four or five feet in height. The leaves are alternate, pinnate, consisting of several pairs of ovate, blunt, petiolate leaflets, with a single leaflet at the end, of a pale-green color, and clammy on their under surface. The flowers are violet or purple, formed like those of the pea, and arranged in axillary spikes supported on long peduncles. The calyx is tubular and persistent. The fruit is a compressed, smooth, acute, one-celled legume, containing from one to six small kidney-shaped seeds. There are two very distinct varieties of the plant yielding the root: in the typical form, or var. *typica*, the underground portion is spreading, producing slender rhizomes. This plant grows best on sandy soil near streams, usually not being found more than fifty meters from a body of water. It is indigenous to southern Europe and southwestern Asia, and is cultivated in England, Germany and Austria and has been grown on an experimental scale in the United States. The second variety, var. *glandulifera*, has been sometimes designated as a distinct species, because the entire plant is pubescent or roughly glandular. The underground portions are not spreading and it produces a large fusiform root. This variety is indigenous to southeastern Europe and in western Asia. It is also cultivated to some extent in Russia. Asiatic licorice, known as "*Chuntschir*," is obtained from *G. uralensis* Fisch. The plant is found in Siberia, Turkestan and Mongolia, and it is claimed that the root is of better quality and is but little inferior to the best Russian licorice. (*Pharm. Journ. Russ.*, 1908, p. 1063; also *P. J.*, 1908, lxxxi, 164.)

It is probable that a portion of the root from Italy and Sicily is the product of *G. echinata*, which grows wild in Apulia. This species is also abundant in the south of Russia, where, according to Hayne, sufficient extract is prepared from it to supply the whole Russian empire. Large quantities of licorice root are now imported for the purpose of making the extract. The annual imports of licorice root in the United States is enormous. Between 75,000,000 and 100,000,000 pounds are annually imported from Turkey and about half of this quantity from Russia. The U. S. Department of Agriculture has had Spanish licorice under cultivation in South Carolina and the plant thrives in various localities in this country. It is said that the soil and climatic conditions in the Coachella Valley of California are ideal for the growing of the licorice plant. Ozmun describes the plantation of licorice in Turkey and the Levant and the manner of harvesting and

handling this article. The licorice plant has been cultivated according to precedence of date in Spain, Italy, Greece, The Ottoman Empire, Russia, China, Turkestan and Persia. (See *Proc. A. Ph. A.*, 1905, p. 273; *A. J. P.*, 1907, p. 39; *Oil, Paint and Drug Rep.*, 1906, p. 37, and 1908, p. 22.)

A species of Glycyrrhiza, *G. lepidota* Pursh., grows abundantly about St. Louis, in the State of Missouri, and flourishes from Colorado to New Mexico, westward into Nevada and Northern California and northward to Washington. It is probably the same as the licorice plant mentioned by Mackenzie as growing on the northern coast of this continent. Nuttall states that its root possesses in no inconsiderable degree the taste of licorice, and M. L. McCullough found it to contain 6.39 per cent. of crude glycyrrhizin, in contrast with 7.18 per cent. in the official species. (*A. J. P.*, 1890.) Schneider reports that *G. lepidota glutinosa* Pursh., a native of California, is much like *G. glabra* and can no doubt be substituted for the true licorice. (*Pacific Pharm.*, II, p. 144.)

Properties.—The two varieties are described in the U. S. Pharmacopœia as follows:

"*Spanish Licorice* (also known as Italian, Levant, Persia, Turkish, or Arabian Licorice)—Nearly cylindrical, upper portion more or less knotty; usually in pieces from 14 to 20 cm. or more in length and from 5 to 20 mm. in thickness; externally yellowish-brown or dark brown, longitudinally wrinkled, the thinner rhizomes often having prominent alternate buds, the thicker rhizomes having distinct corky patches; fracture coarsely fibrous; internally lemon-yellow, radiate; bark from 1 to 3 mm. in thickness; wood porous, in narrow wedges, rhizome with small pith; odor distinctive; taste sweetish and slightly acrid. Under the microscope, transverse sections of pieces of the older rhizome of Spanish Licorice show a periderm of numerous layers of yellowish-brown cork cells, a phellogen and one or more rows of cells of the phelloderm, the cells showing a tendency to collenchymatous thickenings and with occasional monoclinic prisms of calcium oxalate; a middle bark of starch-bearing parenchyma and whitish groups of bast-fibers surrounded with crystal-fibers; inner bark with a very characteristic radial arrangement of phloem and medullary rays, the phloem consisting of wedges of small groups of bast-fibers and parenchyma, separated by an almost continuous, obliterated sieve tissue, the cells of the latter being very irregular in outline and with thick, highly refracting walls; medullary rays from 1 to 8 cells wide; wood characterized by broad wedges consisting of large tracheæ with yellowish walls, small compact groups of wood-fibers and starch-bearing parenchyma alternating with the broad medullary rays; pith composed of parenchyma, the cells being large, more or less polygonal in outline and containing numerous starch grains, or prisms of calcium oxalate. In sections of roots the pith is absent.

"*Russian Licorice.*—Nearly cylindrical, somewhat tapering, sometimes split longitudinally, from 15 to 30 cm. in length and from 1 to 5 cm. in diameter; when deprived of the outer corky layer, it is externally pale-yellow; fracture coarsely fibrous; internally lemon-yellow; wood radially cleft; odor distinct; taste sweetish. Under the microscope, transverse sections of the rhizome and roots of Russian Licorice somewhat resemble those of Spanish Licorice, but the cork cells are absent.

Powdered Glycyrrhiza is pale brownish-yellow (Spanish Licorice) or pale yellow (Russian Licorice); starch grains numerous, mostly single and elliptical or oval, and from 0.002 to 0.02 mm. in diameter; tracheæ mostly with bordered pores; wood- and bast-fibers numerous, strongly lignified, very long, much attenuated at the ends and about 0.01 mm. in width; crystal-fibers with monoclinic prisms of calcium oxalate, the latter from 0.01 to 0.02 mm. in diameter, occasional fragments of red-dish-brown cork cells occur in Spanish Licorice, but are practically absent in the Russian Licorice. Add 10 Gm. of powdered Glycyrrhiza to 100 mils of distilled water, allow the mixture to macerate for fifteen minutes with occasional stirring; and then heat it for one-half hour on a water bath. Filter the mixture and add through the filter enough water to make the filtrate measure 100 mils; not less than 0.2 Gm. of residue remains on evaporating 10 mils of this filtrate and drying it at 100° C. (212° F.). Glycyrrhiza yields not more than 7 per cent. of ash." *U. S.*

"When 5 grammes are macerated with 50 millilitres of *chloroform water* for twenty-four hours, shaken occasionally and filtered, 10 millilitres of the filtrate evaporated in a flat-bottomed dish yield not less than 0.200 gramme of residue dried at 100° C. (212° F.). Ash not more than 6 per cent." *Br.*

Formerly commerce was chiefly supplied with licorice root by Italy and Spain, but the amount coming from these sources is at present probably not more than 10 per cent. of the whole, the greater portion coming from Southern Russia, a large amount from Anatolia and Syria, and a little from Turkey and Persia. The Spanish variety has been most esteemed, but, according to H. N. Rittenhouse, the peeled Russian licorice is richer in glycyrrhizin and extractives than is any other variety, and is in fact the most valuable. Russian licorice is usually very large, quite sweet, but at the same time rather more bitter and acrid than is the Spanish variety. Licorice root is often worm eaten and more or less decayed; such root should be rejected, as should also the small fibrous roots often shipped from Spain. The best pieces are large, bright yellow internally, and have the layers and the bark distinct. Rusby has stated that he has seen ground licorice imported which apparently consisted of the peelings of Russian licorice. (*Ph. Era*, 1909, p. 634.)

A character said by Rothrock (*A. J. P.*,

1884) to be diagnostic is the occurrence of crystal fibers adjoining the wood and bast fibers. These are recognized in the official description of the powdered drug. In the Russian root the parenchymatous wood-cells are larger than in the Spanish. The powder is of a grayish-yellow color, when the root is pulverized without being deprived of its epidermis; of a pale sulphur-yellow, when the epidermis has been removed. Robiquet found the following ingredients in licorice root: (1) a peculiar transparent yellow substance, called *glycyrrhizin*, of a sweet taste, scarcely soluble in cold water, very soluble in boiling water, with which it gelatinizes on cooling, thrown down from its aqueous solution by acids, readily soluble in cold alcohol, insusceptible of the vinous fermentation, yielding no oxalic acid by the action of nitric acid, and therefore wholly distinct from sugar; (2) a crystallizable principle named *agedoïte* by Robiquet, but subsequently proved to be identical with *asparagin;* (3) starch; (4) albumen; (5) a brown acrid resin; (6) a brown nitrogenous extractive matter; (7) lignin; (8) salts of calcium and magnesium, with phosphoric, sulphuric, and malic acids. Flückiger states that a small amount of tannin is also always contained in the root, or rather its bark. The chief constituent, *glycyrrhizin,* $C_{44}H_{68}NO_{18}$, Gorup-Besanez (*Ann. Ch. Ph.,* 118) considered to be a glucoside, as on boiling with diluted acids it breaks up into *glycyrrhetin* and an uncrystallizable sugar capable of fermentation. Roussin (*J. P. C.,* July, 1875) found that the sweet taste of the root was not owing to the free glucoside, but to its compound with ammonia.

Habermann (*Ann. Ch. Ph.,* 197) found that glycyrrhizin-ammonia was the acid ammonium salt of glycyrrhizic acid, a nitrogenous acid, and gave the formula $C_{44}H_{62}NO_{18}.NH_4$ for it. (See *Glycyrrhizinum Ammoniatum.*) He succeeded in extracting from the commercial "ammoniacal glycyrrhizin," *glycyrrhizic acid,* which may be considered to be the active constituent of licorice. It was obtained by dissolving the crude glycyrrhizin in glacial acetic acid at a boiling temperature, rapidly filtering, again treating the crystalline parts of the filtrate in the same manner, and finally purifying by repeated crystallizations from 90 per cent. alcohol. Its properties are peculiar, and account to a great extent for the singular behavior of liquid licorice preparations. With water, in which the substance is but little soluble at ordinary temperature, it forms a transparent, faintly yellow jelly. On mixing 1 Gm. of the body with 100 mils of water, the mixture after a few hours becomes so jelly-like that the open vessel may be inverted without losing any substance. It is insoluble in ether, but slightly soluble in absolute alcohol (even boiling), more so in alcohol of 90 per cent., and especially so when hot. Its solubility increases with the decrease of the percentage of alcohol. The apparent glucosidal character of glycyrrhizic acid Habermann explains by the fact that it breaks up on boiling with diluted sulphuric acid into *glycyrrhetin* and *parasaccharic acid,* according to the reaction:

$$C_{44}H_{68}NO_{18} + 2H_2O = C_{32}H_{47}NO_4 + 2C_6H_{10}O_5.$$

(*Ann. Ch. Ph.,* cxcvii; *N. R.,* Sept., 1879.) By fusing glycyrrhizin with potassium hydroxide, Weselsky and Benedikt (*Ber. d. Chem. Ges.,* 1876) obtained *paraoxybenzoic acid.*

For methods of quantitatively determining glycyrrhizin, see *Ext. Glycyrrh.,* p. 452.

Uses.—Powdered licorice root is used for various pharmaceutical purposes as in the preparation of pills, either to give due consistence or to cover their surface and prevent them from cohering, and as a diluent of powdered extracts, etc. As a remedial agent it has been almost entirely replaced by the extract.

GLYCYRRHIZINUM AMMONIATUM. U. S.

AMMONIATED GLYCYRRHIZIN Glycyrrh. Ammon.

(glĭç-ŷr-rhī-zī'nŭm ąm-mō-nī-ā'tŭm)

"A sweet principle combined with ammonia obtained from glycyrrhiza." *U. S.*

Glycyrhizine Ammoniacale, *Fr. Cod.;* Glyzina, Glyzine, *Fr.;* Ammoniak-Glycyrrhizin, *G.*

The process for making this preparation was omitted from the U. S. P. IX. That of the U. S. P. VIII is appended.

"Glycyrrhiza, in No. 20 powder, *five hundred grammes* [or 17 ounces av., 279 grains]; Water, Ammonia Water, Sulphuric Acid, each, *a sufficient quantity.* Mix *four hundred and seventy-five mils* [or 16 fluidounces, 29 minims] of Water with *twenty-five mils* [or 406 minims] of Ammonia Water, and, having moistened the powder with the mixture, macerate for twenty-four hours. Then pack it moderately in a conical glass percolator, and gradually pour water upon it until *five hundred mils* [or 16 fluidounces, 435 minims] of percolate are obtained. Add Sulphuric Acid slowly to the percolate, with constant stirring, so long as a precipitate is produced. Collect this on a strainer, wash it with cold Water until the washings no longer have an acid reaction, redissolve it in Water with the aid of Ammonia Water, filter, if necessary, and again add Sulphuric Acid so long as a precipitate is produced. Collect this, wash it, dissolve it in a sufficient quantity of Ammonia Water previously diluted with an equal volume of Water, and spread the clear solution upon plates of glass, so that, when dry, the product may be obtained in scales." *U. S. P. VIII.*

The U. S. P. IX describes it as follows: "Ammoniated Glycyrrhizin occurs in dark brown or brownish-red scales, without odor, and having a very sweet taste. It is freely soluble in water and soluble in alcohol. Its aqueous solution when heated with potassium hydroxide T.S. evolves ammonia. Supersaturate an aqueous solution of Ammoniated Glycyrrhizin with an acid; a precipitate is produced (consisting essentially of *glycyrrhizin*), which, when dissolved in hot water, forms a jelly on cooling. This substance, after being washed with diluted alcohol and dried, appears as an amorphous, yellow powder, having a strong, bitter-sweet taste, and an acid reaction. Incinerate 0.5 Gm. of Ammoniated Glycyrrhizin; not more than 0.5 per cent. of ash remains." *U. S.*

This is a preparation whose introduction is a result of the researches of Z. Roussin, communicated to the Société de Pharmacie of Paris, June 2, 1875. This investigator noticed that *glycyrrhizin*, the sweet principle of licorice root, is insipid when compared with the root itself, and suspected that it existed in a modified form in the root. Experiment showed that alkalies developed the sweet taste, and he ultimately proved that the alkali with which it was combined in the root was ammonia, and that glycyrrhizin played the part of an acid. He named the compound *ammonium glycyrrhizate*, and called attention to the fact that licorice root which had lost a portion of its sweetness through fermentation and the development of acetic acid and precipitation of insoluble glycyrrhizin could be restored to its former sweetness if allowed to remain a sufficient length of time in an ammoniacal atmosphere. The U. S. P. VIII process for ammoniated glycyrrhizin is closely modelled after Roussin's, with the exception of the substitution of percolation by a slightly ammoniated menstruum for maceration and expression with cold water. Roussin purified his product by redissolving it in alcohol and precipitating with ether; this is deemed unnecessary for a preparation which is intended to be useful without being expensive. (See *Proc. A. Ph. A.*, 1876, p. 544.)

Connerade proposed some modification of Roussin's method; his process is as follows: "Macerate ground liquorice root with one and a half parts by weight of water, strain, wash the residue with a very small quantity of water, heat the mixed liquids to boiling to coagulate albumen, strain again, and then add diluted sulphuric acid (1 in 10), as long as a precipitate is produced. Let this settle, decant the liquid, and dissolve the precipitate in solution of ammonia, diluted with nine parts of water. Filter the latter and evaporate it to dryness. The compound then remains as a brown, friable varnish, unaltered by air, of a pure, sweet taste, easily soluble in cold water, and imparting to the latter, even when diluted to 1 in 1000 parts, an amber color. The yield is about 10 per cent. of the weight of the root." (*N. R.*, March, 1881.)

Uses.—This substance appears to possess the medicinal properties of licorice, and may be used as an elegant substitute for it in mixtures which are neither acid nor alkaline. It is incompatible with acids which destroy its sweetness by throwing down the insoluble glycyrrhizic acid.

Dose, from five to fifteen grains (0.32–1.0 Gm.).

GOSSYPII RADICIS CORTEX. Br.

COTTON ROOT BARK

(gŏs-sĭp'I-I răd'ĭ-cĭs cŏr'tĕx)

"Cotton Root Bark is the dried root-bark of Gossypium herbaceum, *Linn.*, and of other cultivated species of Gossypium." *Br.*

"The recently-gathered air-dried bark of the root of one or more of the cultivated varieties of *Gossypium herbaceum* Linné, *Gossypium Barbadense* Linné, or *Gossypium arboreum* Linné (Fam. *Malvaceæ*), without the presence of more than 5 per cent. of wood or other foreign matter." *N. F.*

Gossypii Cortex, *N.F.*; Ecorce de la Racine de Cottonnier *Fr.*; Baumwoll-Wurzelrinde, *G.*; Corteza de la raiz d'algodon, *Sp.*

In consequence of changes produced in the plants of this genus by cultivation, botanists have found great difficulty in determining which are distinct species and which are merely varieties. By some taxonomists more than fifty species of *Gossypium* are recognized. There are only 5 or 6 species which yield useful products and the bulk of the cotton is the product of two species: *G. herbaceum* L., which furnishes the Upland or short staple cotton, and *G. barbadense* L., the source of the Sea Island or long staple cotton. All of the species are of tropical origin. The Upland cotton has been cultivated in East India and Arabia since ancient times. The Sea Island cotton is indigenous to America and is of the type observed by Columbus.

Gossypium herbaceum is a biennial or triennial plant, with a branching stem from two to six feet high, and palmate hoary leaves, the lobes of which are somewhat lanceolate and acute. The flowers possess yellow petals, having a purple spot near the claw. The leaves of the involucre or outer calyx are serrate. The capsule opens when ripe, and displays a loose white tuft of long slender filaments, which surround the seeds and adhere firmly to the outer coating. The plant is a native of Asia, but is cultivated in most tropical countries. It requires a certain duration of warm weather to perfect its seeds, and, in the United States, does not mature north of Virginia.

The herbaceous part of the plant contains much mucilage, and has been used as a demulcent. The seeds yield by expression a fixed oil of the semi-drying kind, which is employed for making soap and for other purposes. (See *Oleum Gossypii.*) The bark of the root has been supposed to possess medicinal virtues, and is recognized by the National Formulary IV. Another portion, for which the plant is cultivated, is the filamentous substance surrounding the seeds. This, when separated, constitutes the cotton of commerce, and when purified, is

official as *Purified Cotton.* Cotton seeds have been employed in our Southern States with great asserted success in the treatment of intermittents, but are at present seldom, if ever used. (For details, see *U. S. D.*, 16th ed.) For an account of a microscopical and microchemical examination of cotton root bark by F. W. Morgan, see *A. J. P.*, 1898, p. 427. Farwell has made a histological study of the root and stem barks. (See *Merck's Rep.*, 1914, p. 133.) The drug of commerce frequently contains a considerable woody material. It is said it deteriorates with age and therefore only recently gathered bark should be used.

Properties.—Cotton Root Bark is described as: "In strips or quilled pieces; thin, tough and fibrous. Cork thin, pale brown, longitudinally striated; removed in places and then disclosing the orange-brown cortex. Inner surface whitish, silky and finely striated. Secondary bast readily separable into thin fibrous laminæ. No odor; taste slightly acrid and astringent." *Br.*

The N. F. describes the bark as follows: "In flexible bands or quilled pieces, attaining a length of 30 cm. and a thickness of about 1 mm.; outer surface orange-brown, smooth, slightly wrinkled, with small circular lenticels, the outer corky layer frequently exfoliated and showing the more or less fissured and fibrous middle bark; inner surface light brown, longitudinally striate; fracture tough, fibrous, the inner bark readily separable into fibrous layers. Odor slight; taste very slightly acrid. Under the microscope, sections of Cotton Root Bark show an outer layer of cork composed of four to six layers of tabular, thin-walled, yellowish-brown, non-lignified cells; a thin primary cortex, consisting of starch-bearing parenchyma and an occasional large secretion reservoir with yellowish-brown contents; inner bark with large groups of bast fibers arranged in interrupted, concentric circles, separated radially by medullary rays and tangentially by the leptome or sieve tissue; bast fibers from 0.3 to 1 mm. in length and about 0.015 mm. in width, the walls being about 0.005 mm. in thickness, strongly lignified and with very few pores, the ends being acute and markedly attenuate; medullary rays one to six cells wide, the cells usually filled with starch grains; the latter from 0.003 to 0.02 mm. in diameter; occasional cells containing rosette aggregates of calcium oxalate from 0.009 to 0.025 mm. in diameter. Cotton Root Bark yields not more than 7 per cent. of ash." *N. F.*

E. S. Wayne, of Cincinnati, found in it a peculiar acid resin, colorless and soluble in water, when pure, but absorbing oxygen on exposure, and then becoming red and insoluble in water. It is deposited from the fluidextract on standing. He suggests that this may be the active principle of the root; but the fact has not been determined. (*A. J. P.*, 1872.) William C. Staehle (*A. J. P.*, 1875) made an examination of this resin, and obtained results somewhat different from those of Wayne. Staehle's percolate was of a dark reddish-brown color, while Wayne's was pale amber. This is accounted for, however, by the presence of a principle which is colorless in the fresh bark, but of a dark red in bark which has been exposed to air and light. W. A. Taylor noticed that the change in color from pale amber to dark red took place in an alcoholic tincture. (*A. J. P.*, 1876.) Staehle found the resin soluble in 14 parts of alcohol, 15 parts of chloroform, 23 parts of ether, and 122 parts of benzene.

Power and Browning (*P. J.*, 1914, xciii, 420) found in an investigation of cotton root bark the following constituents: acetovanillone (in the steam distillate), a phenolic acid (probably two-thirds dihydroxybenzoic acid), salicylic acid, a new colorless phenolic substance, $C_9H_{10}O_3$, a new yellow phenolic substance, $C_{13}H_{18}O_5$, betaine, a fatty alcohol, $C_{20}H_{42}O$, a phytosterol, $C_{27}H_{46}O$, triacontane, ceryl alcohol, oleic and palmitic acids, and a sugar. Almost all of these constituents were separated from the resinous extractive which constituted between 10 and 11 per cent. of the air dried bark. No tannin was present and no alkaloids were detected.

Uses.—Cotton root bark was introduced into medicine by Bouchelle (*A. J. M. S.*, August, 1840), who stated that it was habitually resorted to by the slaves of the south as an abortifacient. His favorable opinion has been confirmed by various southern practitioners, and Scott (*T. G.*, 1911) has shown experimentally that cotton root bark increases the contractions and tonus of the uterus in the lower animals, although it is somewhat less powerful than ergot. It is used not only to strengthen the contractions in uterine inertia during *labor,* but also in the treatment of *metrorrhagias,* especially when dependent on *fibroids.* Bellany, of Georgia, asserts that the root should be gathered as late as possible in the fall before frost. Bouchelle used a decoction made by boiling four ounces of the inner bark of the root in a quart of water down to a pint, of which he gave a wine glass full (60 mils) every twenty or thirty minutes. The U. S. P., 1890, recognized a fluidextract (see *U. S. Dispensatory,* 19th edition, p. 525); for the N. F. IV fluidextract, see Part III.

Dose, thirty to sixty grains (2.0–3.9 Gm.).

Off. Prep.—Decoctum Gossypii Radicis Corticis, *Br.;* Extractum Gossypii Radicis Corticis Liquidum, *Br.;* Fluidextractum Gossypii Corticis, *N. F.*

GOSSYPIUM PURIFICATUM. U. S. (Br.)

PURIFIED COTTON Gossyp. Purif.
[Absorbent Cotton]
(gŏs-sȳp'ĭ-ŭm pū-rĭ-fĭ-cā'tŭm)

"The hairs of the seed from one or more of the cultivated varieties of *Gossypium herbaceum* Linné (Fam. *Malvaceæ*), freed from adhering impurities and linters and deprived of fatty matter." *U. S.* "Cotton consists of the hairs of the seed of Gossypium herbaceum, *Linn.,* and of other cultivated species of Gossypium, freed from fatty matter." *Br.*

Gossypium, *Br.;* Cotton Wool; Lana (Lanugo, s. Pili) Gossypii; Coton Hydrophile, *Fr. Cod.;* Coton absorbant, Xylum præparatum, *Fr.;* Gossypium depuratum, *P. G.;* Gereinigte Baumwolle, Baumwolle, *G.;* Cotone assorbente, C. idrofilo, *It.;* Algodon hidrofilo, Algodon absorbente, *Sp.*

There is considerable difference in the capsules or so-called bolls, the seeds, as well as the lint of the several species of Gossypium. The bolls of Sea Island (*G. barbadense*) cotton are uniformly smaller, more sharply pointed, contain fewer and smaller seeds and longer lint than the Upland bolls. The Sea Island cotton has small black seeds from which the lint separates readily. The Upland cottons have large seeds which are greenish in color, and surrounded by a short, dense hair beneath the longer and more valuable lint. The lint of the Sea Island cotton is from 3.5 to 6.5 cm. in length, while the Upland cotton seldom exceeds 3.5 cm. in length, usually being much shorter. There are numerous hybrids between these two types, *G. herbaceum* and *G. barbadense.* The long and extra long fiber produced in the United States are all obtained from varieties of *G. barbadense* and their hybrids, the shorter fibers being usually Upland cottons of the *G. herbaceum* type. The commercial grading of cotton by the New York Cotton Exchange is as follows: Samples the average fiber of which is under 25 mm. in length are called "short staple"; those between 25 to 30 mm. are called "medium" and from 30 to 40 mm. are called "long staple." What are known as "full grades" are designated by the words "fair," "middling fair," "good middling," "middling," "low middling," "good ordinary" and "ordinary."

Properties.—"Purified Cotton occurs in white, soft, fine filaments, appearing under the microscope as hollow, flattened and twisted bands, spirally striate, and slightly thickened at the edges; inodorous and almost tasteless; insoluble in ordinary solvents, but soluble in an ammonia solution of cupric oxide. When Purified Cotton, previously compressed in the hand, is thrown on the surface of cold water, it readily absorbs the latter and sinks. Incinerate 5 Gm. of Purified Cotton; not more than 0.2 per cent. of ash remains. Thoroughly saturate about 10 Gm. of Purified Cotton with 100 mils of distilled water, then with the aid of a glass rod press out two portions of the water, 25 mils each, into white porcelain dishes. Add to one portion 3 drops of phenolphthalein T.S. and to the other portion 1 drop of methyl orange T.S.; no pink color develops in either portion (*alkali or acid*). Extract 5 Gm. of Purified Cotton, tightly packed in a narrow percolator, with ether, until the percolate measures 20 mils, and evaporate this to dryness; the residue does not exceed 0.6 per cent. (*fatty matter*). Extract 10 Gm. of Purified Cotton, in a narrow percolator, with alcohol, until the percolate measures 100 mils. When observed downward through a column 20 cm. in depth, the percolate may show a yellowish color, but no blue or green tint (*dyes*); and, on evaporating this percolate to dryness, the weight of the residue does not exceed 0.5 per cent. (*resins and soap*)." *U. S.*

"In long, white, soft filaments, each consisting of an elongated cell, appearing, when seen under the microscope, as a flattened, twisted band with slightly thickened rounded edges. Inodorous and tasteless. Soluble in *ammoniacal solution of copper oxide.* Readily wetted by *water,* and not imparting to it either an alkaline or an acid reaction. Ash not more than 0.5 per cent." *Br.*

It is without odor or taste, soluble in strong alkaline solutions, and decomposed by the concentrated mineral acids. In chemical character it is related to but not identical with lignin, the latter being a very different product and called *lignocellulose.* By nitric acid it is converted into gun cotton, for an account of which see *Pyroxylinum* and *Collodium.* *Mercerized cotton* is made by treating woven cotton fabrics with concentrated sodium hydroxide solution which so modifies the fiber that a sheen-like silk is produced. This must not be confused, however, with artificial silk which is made by several processes in which cotton or cellulose is taken as the starting point. In one of these the cellulose is converted into a nitroderivative which, after dissolving in suitable solvents to make a thick solution, is drawn out into threads which are subsequently denitrated and made less inflammable by immersing them in alkaline sulphide solution. In another method the cellulose is treated with alkali and carbon disulphide which forms cellulose thiocarbonate or xanthate which when treated with water yields "*viscose,*" a thick tenacious substance capable of being drawn into glossy threads, which is sold as *artificial silk,* and also used as bottle caps.

In the process of purifying cotton a soap is formed through the union of the fatty matter with the alkali, and this is subsequently dissolved out by repeated washings. F. L. Slocum published in 1881 a process for preparing it as follows: Take of the best quality of carded cotton batting any desired quantity, and boil it with a 5 per cent. solution of potassium or sodium hydroxide for one-half hour, or until the cotton is entirely saturated with the solution, and the alkali has saponified all oily matter. Then wash thoroughly, to remove all soap, and nearly all alkali; press out the excess of water, and immerse in a 5 per cent. solution of chlorinated lime for 15 or 20 minutes; again wash, first with a little water, then dip in water acidulated with hydrochloric acid, and thoroughly wash with water; press out the excess of water, and again boil for 15 or 20 minutes in a 5 per cent. solution of potassium or sodium hydroxide; now wash well, dipping in the acidulated water and washing thoroughly with pure water. Afterwards press out and dry quickly.

The amount of loss by this process is practically 10 per cent. A sample of 360 gr. lost, on boiling with alkali and bleaching, 15 gr., or 4.17 per cent., and 270 gr. of this bleached sample lost, on again boiling with an alkali, 14 gr., or

5.18 per cent., a total loss of 9.35 per cent. (*A. J. P.*, 1881, p. 53. See also *Ph. Era.*, 1890, 22.)

Wood Wool.—Under this name Bruns has introduced finely grained, purified wood fiber, such as is used in making paper. It may be medicated like cotton.

The first U. S. P. IX test proves the absence of fatty matter, for if even a small quantity be present the cotton will float in water. Repeated experiments have proved that cotton will take fire and burn spontaneously if impregnated with linseed oil, or some of the other fixed oils, and allowed to stand, whereby the heat of the oxidation of the oil suffices to ignite the matted fibers of the cotton. Raw cotton, analyzed by M. Schunck, was found, independently of cellulose ($C_6H_{10}O_5$)n, of which it chiefly consists, to contain vegetable wax, a fatty acid, coloring matter, pectic acid, and a little of an albuminoid substance. (*J. P. C.*, Sept., 1868, 233.) For medicinal use it should be carded into thin sheets. Air passed through cotton becomes sterile on account of the microscopic organisms being strained out of it; and this fact has been utilized in preserving infusions by placing them in bottles containing corks armed with tubes loosely filled with cotton, and drawing the infusion from a stopcock near the bottom.

Uses.—The use of cotton as a filtering medium and in the preparation of medicated waters has already been alluded to. It is much used in surgery as a dressing for *burns, scalds, blisters,* and *wounds,* in order to prevent the access of pathogenetic germs and to absorb discharges. Cotton batting is often employed to maintain a uniform temperature in parts affected with *acute rheumatic inflammation.* Absorbent cotton has been medicated in various ways and come largely into use. (For *Iodized Cotton,* see page 593.) *Picric Cotton* is prepared by dissolving 0.25 Gm. of picric acid in 25 Gm. of ether, or of 94 per cent. alcohol, and immersing in the solution 10 Gm. of clean cotton, and drying. *Salicylic Cotton* (5 per cent.) may be prepared by Brun's process, by saturating one kilogramme of cotton with 4 liters of a solution of 50 Gm. of salicylic acid, and 20 Gm. of castor oil in 3.930 liters of alcohol. *Benzoic Cotton* is made in the same way, substituting benzoic for salicylic acid. *Chlorinated Cotton.* Pavesi subjects cotton moistened with glycerin, and suspended at the top of a large wide-mouthed bottle, to the action of chlorine vapor, generated by adding sulphuric acid to chlorinated lime. (*N. R.*, July, 1880.) Joseph W. England communicates in *A. J. P.*, 1887, p. 173, practical formulas for preparing the following medicated cottons and gauzes: *Borated Cotton, Benzoated Cotton, Salicylated Cotton, Naphthalinated Cotton, Iodoformized Cotton, Carbolized Cotton, Sublimated Cotton, Carbolized Gauze, Sublimated Gauze, Absorbent Canton Flannel.* For methods of assay of medicated cottons, gauzes, etc., see *Proc. A. Ph. A.*, 1897, 457, 458, 459. See also formulas for the extemporaneous preparation of medicated gauzes, by George M. Beringer, Jr., *A. J. P.*, 1911, p. 178.

Off. Prep.—Pyroxylinum, *Br.;* Gossypium Stypticum, *N. F.*

GRANATUM. U. S.

POMEGRANATE Granat. [Pomegranate Bark]

(grą-nā'tŭm)

"The dried bark of the stems and roots of *Punica Granatum* Linné (Fam. *Punicaceæ*), without the presence or admixture of more than 2 per cent. of wood or other foreign matter. Preserve it in tightly-closed containers." *U. S.*

Granati Cortex, *Br.*, 1898; Pomegranate Bark; Grenadier, *Fr. Cod.;* Ecorce de la Racine de Grenadier (de Balaustier), Ecorce de Granade, *Fr.;* Cortex Granati, *P. G.;* Granatrinde, Granatwurzelrinde, *G.;* Melograno to, Malicorio, Scorza del Melograno ti, *It.;* Granada (Corteza de), *Sp.*

The *pomegranate* is a small tree, attaining in favorable situations the height of twenty feet, with a very unequal trunk, and numerous branches which sometimes bear thorns. The leaves are opposite, petiolate, entire, oblong or lance-shaped, pointed at each end, smooth, shining, and of a bright-green color. The flowers are large, of a rich scarlet color, and stand at the end of the young branches. The petals are roundish and wrinkled, and are inserted into the upper part of the tube of the calyx, which is red, thick, and fleshy. The fruit is a globular berry, about the size of an orange, crowned with the calyx, covered with a reddish-yellow, thick, coriaceous rind, and divided internally into many loculi, which contain an acidulous pulp, and numerous oblong, angular seeds.

This tree grows wild upon both shores of the Mediterranean, in Arabia, Persia, Bengal, China, and Japan, has been introduced into the East and West Indies, and is cultivated in all civilized countries where the climate is sufficiently warm to allow the fruit to ripen. In higher latitudes, where it does not bear fruit, it is raised in gardens and hot houses for the beauty of its flowers, which become double and acquire increased splendor of coloring by cultivation. Doubts have been entertained as to its original country. The name of *Punicum Malum,* applied by the ancients to its fruit, implies that it was abundant at an early age in the vicinity of Carthage. The fruit, for which the plant is cultivated, varies much in size and flavor. It is said to attain greater perfection in the West Indies than in its native country. The edible pulp is red, succulent, pleasantly acid, and sweetish. The flowers were recognized by the Dublin College, and the seeds are official in France. See a paper by J. U. Lloyd in *West. Drug.*, 1897, 202.

The pomegranate may be grown in the United States as far north as Virginia. It is cultivated to some extent in California, and the Gulf States as a garden and hedge plant. The seeds are utilized in the south in making cooling drinks. There are several varieties of the pomegranate. The typical having an acid pulp, and others having a sweet and sub-acid character. There is an East Indian variety which is seedless and is highly prized in India. There are several double-

flowered varieties which do not bear fruit and are largely cultivated in the south and in greenhouses for ornamental purposes.

The *rind of the fruit* is seen in commerce in the form of irregular fragments, hard, dry, brittle, of a yellowish or reddish-brown color externally, paler within, without odor, and of an astringent, slightly bitter taste. It contains a large proportion of tannin, and in countries where the tree abounds, has been employed for tanning leather.

The flowers, sometimes called *balaustines,* are inodorous, have a bitterish, astringent taste, and impart a violet-red color to the saliva. They contain tannic and gallic acids, and were used by the ancients in dyeing.

Properties.—"The stem bark is mostly in somewhat flattened or transversely curved pieces, to some extent in quills, from 2 to 8 cm. in length; bark from 0.5 to 3.5 mm. in thickness; outer surface yellowish to grayish-brown, with grayish patches of foliaceous lichens with their brownish-black apothecia, longitudinally wrinkled, also marked with small, broadly elliptical lenticels and with more or less abraded patches of cork; inner surface light yellow or yellowish-brown, finely striate; fracture short, smooth, inner bark yellowish-green; odor slight; taste astringent, somewhat bitter and nauseous. The root bark is in transversely curved pieces; externally brownish-yellow to dark brown with irregular patches of cork; internally dark yellow, the medullary rays extending nearly to the outer surface. The powder is yellowish-brown to dark brown; calcium oxalate crystals in rosette aggregates, monoclinic prisms or crystal fibers, the individual crystals from 0.01 to 0.018 mm. in diameter; starch grains numerous, spherical, ellipsoidal biconvex, polygonal or irregular, and single or compound, from 0.002 to 0.01 mm. in diameter; fragments of whitish cork with strongly lignified walls; stone cells mostly single, occasionally in small groups, the individual cells from 0.05 to 0.18 mm. in length, the walls being very thick and strongly lamellated; occasional fragments of wood with long wood-fibers from 0.015 to 0.02 mm. in width, the walls being slightly lignified and from 0.003 to 0.008 mm. in thickness and associated with tracheæ possessing simple and bordered pores. Mix 1 Gm. of powdered Pomegranate with 100 mils of distilled water, macerate it with occasional agitation for about an hour and filter; a light yellow filtrate is obtained. Upon the addition of a drop of ferric chloride T.S. to 10 mils of this filtrate a bluish-black precipitate is produced. Upon the addition of from 40 to 50 mils of lime water to another portion of 10 mils of the filtrate, an orange-brown, flocculent precipitate is produced. Pomegranate yields not more than 16 per cent. of ash." *U. S.*

The roots of the pomegranate are hard, heavy, knotty, ligneous, and covered with a bark which is yellowish-gray or ash-gray on the outer surface, and yellow on the inner. The *root bark* occurs in quills or fragments similar to but differing from those of the stem as shown in the official characterization. "The transverse section exhibits numerous fine radial and tangential lines." *Br.* (1898). It has little or no odor, colors the saliva yellow when chewed, and leaves in the mouth an astringent taste without disagreeable bitterness. There is considerable question as to the relative value of the root and stem barks of *granatum.* The drug of commerce usually consists of a mixture of stem and root bark, the former commonly predominating. Granatum is sometimes substituted by the barks of other plants. The principal of these being *Berberis vulgaris,* which is bitter and not astringent; *Buxus sempervirens,* which is also bitter and free from tannin; and *Strychnos Nux Vomica* or false Angostura bark which has a dark inner surface and a very bitter taste. None of these barks have the characteristic checkered appearance of the transverse surface of genuine Granatum.

The bark of the stem of the pomegranate is sold as root bark: for microscopic diagnosis, see *P. J.,* 1873. As the activity of the barks of different portions of the plant is important, represented by the alkaloids the analyses of Stoeder are of interest. His results are: stem and branch bark, in thin quills, 0.612 per cent.; average quills, 0.350 per cent.; thick quills, 0.498 per cent.; root bark from south of Europe, in thick quills, 1.010 per cent.; shaved root bark from Java, 1.326 per cent.; exfoliated bark from dry thick roots of unknown age, 1.240 per cent.; finely rasped wood from these roots, 0.218 per cent. According to the same authority (*Nederl. Tijd. Pharm.,* 1890), of the bark of three varieties of the wild pomegranate recognized and used by the natives of Java, the red-flowered "merah," yielded 2.43 per cent.; the white-flowered, "poetih," yielded 3.75 per cent.; the black-flowered, "hitam," yielded 1.71 per cent.

The infusion of granatum yields a deep-blue precipitate with salts of iron, and a yellowish-white precipitate with solution of gelatin. The inner surface of the bark, steeped in water and then rubbed on paper, produces a yellow stain, which by the contact of ferrous sulphate is rendered blue, and by that of nitric acid acquires a slight rose tint, which soon vanishes. These properties serve to distinguish this bark from those of the box root and barberry. When used, it should be separated from the ligneous portion of the root, as the latter is inert. The bark contains more than 22 per cent. of tannic acid, which Rembold (*Ann. Ch. Ph.,* 143, 285) found to consist for the most part of a peculiar variety, *punico-tannic acid,* $C_{30}H_{16}O_{13}$; when boiled with diluted sulphuric acid it is resolved into *ellagic acid,* $C_{14}H_8O_9$, and sugar. Punico-tannic acid is accompanied by common tannic acid, yielding by means of sulphuric acid, gallic acid, which appears sometimes to pre-exist in the bark. Henry Trimble, however (*A. J. P.,* 1897, 636), as the result of an ultimate analysis of the purified tannin and a study of its reactions, pronounced it to be identical with gallo-

tannic acid. Pomegranate bark also yields a considerable quantity of *mannite,* which was formerly described under the names of *punicin* or *granatin.* The medicinal value of the root, however, is due, according to Tanret (*C. R. A. S.,* lxxxvi, 1270, and lxxxvii, 358), to an alkaloid *pelletierine,* $C_8H_{15}NO$, a dextrogyrate liquid boiling at 195° C. (383° F.), easily soluble in water, alcohol, and ether, and specially so in chloroform. It has strong basic properties and precipitates many metallic salts: 1000 parts of dry bark yielded 4 parts of it.

Tanret (*C. R. A. S.,* lxxxviii, p. 716) announced that he had found three additional volatile bases in the bark, a liquid left-rotating one, a liquid optically inactive one, and a crystallizable inactive one, to which the names of *methylpelletierine,* $C_9H_{17}NO$, and *pseudopelletierine* (*granatonine*), $C_9H_{15}NO$, and *isopelletierine,* have been given. Carl J. Bender (*Ph. Centralh.,* 1885, p. 6) found three bases in pomegranate bark, one crystallizable and two amorphous. He objects to the name pelletierine, and substitutes *punicine.* Wm. F. Junkunz analyzed pomegranate bark, and believed that the alkaloid exists in the bark as a tannate. (*A. J. P.,* 1884.) The old idea that the bark loses activity when kept seems to be negatived by the analysis of De Vrij. (*P. J.,* xxi.) Piccinni isolated a tertiary alkaloid, $C_{10}H_{13}NO$, from pomegranate root bark. (*P. J.,* 1900, 249.) Flückiger stated that methyl pelletierine predominates in the bark of the root and pelletierine in the bark of the overground portions of the plant. For Leger's method of determining total alkaloids, see *P. J.,* 1904, 581. Assay processes for granatum are given in most of the foreign pharmacopœias and these were critically reviewed by Dichgans (*Ph. Ztg.,* 1914, 852), who finds the one in the Swiss Pharmacopœia to be the best.

Uses.—The rind of the pomegranate fruit was formerly recognized by the U. S. Pharmacopœia. It is astringent, and in the form of decoction is sometimes employed in *diarrhea* and *colliquative sweats,* and, more frequently, as an injection in *leucorrhea,* and as a gargle in *sore throat* in the earlier stages, or after the inflammatory action has in some measure subsided. The powdered rind has also been recommended in *intermittent fever.* The flowers have the same medicinal properties and are used for the same purposes. The bark of the root was used by the ancients as a vermifuge, and is recommended in the writings of Avicenna, but was unknown in modern practice until brought into notice by F. Buchanan, who learned its powers in India. The Mahometan physicians of Hindostan consider it a specific against *tænia.* One of these practitioners, having relieved an English gentleman in 1804, was induced to disclose his secret, which was then made public. The French writers prefer the product of the wild pomegranate, growing on the borders of the Mediterranean, to that of the plant cultivated in gardens for ornamental purposes. The bark may be administered in powder or decoction, but the latter form is usually preferred. The decoction is prepared by macerating two ounces of the bruised bark in two pints of water for twenty-four hours, and then boiling to a pint. Of this a wineglassful may be given every half hour, hour, or two hours, until the whole is taken. It often nauseates and vomits, and usually purges. Portions of the worm often come away soon after the last dose. It is recommended to give a dose of castor oil and to diet the patient strictly on the day preceding the administration of the remedy, and, if it should not operate on the bowels, to follow it by castor oil, or an enema. If not successful on the first trial, it should be repeated daily for three or four days, until the worm is discharged. It appears to have been used by the negroes of San Domingo before its introduction into Europe.

Pomegranate owes its anthelmintic powers to the alkaloids, pelletierine and isopelletierine, the mixture of which is official. The efficacy of these tænicides has been abundantly confirmed, and it appears to be established that the tannate is the most effective and the least dangerous form of the remedy,—probably because its insolubility prevents its rapid absorption and enables it to come in prolonged contact with the worm. The experiments of Dujardin-Beaumetz have shown that the alkaloids from pomegranate act upon the higher animals like curare, causing paralysis of the motor nerves without affecting sensation. The same authority asserts that hypodermic injections of six grains produce in man severe vertigo, muscular weakness, and great retinal congestion. Double vision has also been noted, and Galezowski has been led by it to prescribe pelletierine in paralysis of the third and sixth pairs of nerves; he affirms that he has succeeded in affording relief after the failure of potassium iodide and blisters. The proper dose of pelletierine tannate is variously given by authorities. It has been stated to be from one-half to three-quarters of a grain (0.032–0.048 Gm.) (*B. G. T.,* xcvi, xcvii), but others place it as high as eight grains (0.5 Gm.). Commercially, it occurs almost exclusively as a syrupy solution, put up, we believe, under the supervision of its discoverer, each bottle containing a single dose, it is stated, of about five grains (0.32 Gm.). We have seen pronounced temporary general palsy produced in a female adult by this dose. The dose of pomegranate rind and flowers in powder is from twenty to thirty grains (1.3–2.0 Gm.). *Decoctum Granati Corticis* was formerly official in the British Pharm. (1898). The decoction may be prepared in the proportion of four ounces of the bark to twenty fluidounces of water, and given in the dose of half a fluidounce (15 mils). The remedy should always be given after a twelve hours' fast, and be followed in two hours by a brisk cathartic. The seeds are demulcent.

Dose, twenty to thirty grains (1.3–2.0 Gm.).

GRINDELIA. U. S., Br.

GRINDELIA Grindel.

(grĭn-dē'lĭ-ą)

"The dried leaves and flowering tops of *Grindelia camporum* Greene, or *Grindelia cuneifolia* Nuttall, or *Grindelia squarrosa* (Pursh.) Dunal (Fam. *Compositæ*), without the presence or admixture of more than 10 per cent. of stems or other foreign matter." *U. S.* "Grindelia consists of the dried leaves and flowering tops of Grindelia camporum, *Greene*." *Br.*

California Gum-plant; Grindelia, *Fr.*; Grindelie, *G.*

The genus Grindelia includes some twenty-five species, six or eight of which are found in South America and the remainder occurring in the United States west of the Mississippi. They are coarse perennial or biennial herbs, being occasionally shrub-like. Most, if not all, of the species produce a resinous exudation on the stem and leaves and especially on the flower-heads. The leaves are alternate, sessile or clasping and spinulose-dentate. The flowers occur in large terminal heads composed of both discoid and radiate yellow flowers. The ray flowers are pistillate and the involucre is more or less hemispherical, the bracts being imbricated, in several series, being usually subulate-tipped. The drug of the market appears to be derived in large part from *G. camporum* Greene, which is the common "*gum plant*" of California. It occurs abundantly in the inner coast ranges, where it has been collected in quantity in Lake and Napa Counties. It is also common in the foot hills of the Sierra Nevada and is almost the only plant found on the plains in certain regions of the Sacramento Valley. The leaves are oblong or spatulate, sessile or clasping, coarsely serrate and of a pale-green color. The flower-heads are yellow and the involucre consists of several rows of lanceolate acuminate recurved bracts. The achenes are distinctive in this species and are usually biauriculate or more rarely unidentate at the summit.

G. cuneifolia closely resembles *G. camporum*. The leaves are cuneate oblong or linear oblong and either sessile or amplexicaul. It is a marsh plant and is not as glutinous as *G. camporum*. The leaves of this species, in addition to their being cuneiform in shape, are darker green and not so thick as in *G. camporum*. The achenes are compressed and closely resemble those of *G. camporum*.

G. squarrosa is a common plant on the prairies and dry banks of the West. It has been reported as occurring from the Saskatchewan to Minnesota, Texas and California. It is a glabrous, erect, branching herb having linear-oblong or spatulate leaves, which are more or less clasping at the base and sharply spinulose-dentate. It is especially characterized by the bracts of the involucre being linear-lanceolate, subulate tipped and spreading or squarrose at the summit, giving the species its name. The achenes are truncate, those of the outer flowers being usually thicker. The pappus consists of two or three awns.

It was formerly supposed that the drug of commerce was derived from *G. robusta*. The studies of Perrédès (*Proc. A. Ph. A.*, 1906, 370) showed this not to be the case. *G. robusta* is apparently not a very common plant and is distinguished by having cordate-oblong, amplexicaul, coarsely serrate leaves. The involucre is squarrose and leafy at the base. The pappus consists of two awns. At one time both *G. cuneifolia* and *G. camporum* were considered merely as varieties of *G. robusta*.

According to Joseph Beauvais (*A. J. P.*, Feb., 1889), the resin of the leaf of *G. robusta* is contained in epidermal glands, and also in rather large resin-ducts situated in an interior collenchymatous layer.

Properties.—The official description of grindelia is as follows: "Stems with attached branches terminated with resinous flower-buds; stems cylindrical, not exceeding 2 mm. in diameter; light yellow or rose-colored, with alternate leaf-scars, occasionally with basal portions of leaves, sometimes more or less irregularly flexuous and coated with resin, especially at the nodes; leaves usually separate and more or less broken and varying in shape when entire from oblong and lanceolate to oblanceolate-spatulate and cuneate-spatulate, from 1 to 7 cm. in length, mostly sessile or amplexicaul and more or less sharply serrate or evenly spinosely-toothed, pale yellow to yellowish-green, very resinous, somewhat coriaceous and brittle; bracts of flowering branches almost entire and usually more or less spreading; heads more or less resinous, viscid, many-flowered, either conical-urceolate or depressed-urceolate, involucres from 5 to 20 mm. in breadth, composed of numerous imbricated bracts with more or less recurved tips; ray flowers yellow, ligulate and pistillate; disk florets yellow, tubular and perfect; pappus of two or three mostly unequal linear awns about the length of the disk florets; disk achenes more or less ovoid or oblong; more or less compressed or triquetrous, and either biauriculate or broadly unidentate or with a broad truncate corky, thickened summit; odor balsamic; taste aromatic and bitter, resinous. The powder is yellowish-brown; consisting of numerous fibrous fragments made up of tissues of the stem, the most prominent being the tracheæ with annular and spiral thickenings or marked with simple or bordered pores, associated with numerous, narrow, strongly lignified wood-fibers; pith cells more or less tabular and containing a layer of protoplasm in which are embedded numerous spheroidal granules; fragments of epidermis of leaves very characteristic and showing more or less polygonal areas containing large chloroplastids, and the large, colorless, basal cells of the multicellular glandular hairs; pollen grains spherical, about 0.035 mm. in diameter, spinose, and in section showing three pores." *U. S.*

"Stems slender, yellow, smooth. Leaves three to five centimetres long, oblong or spatulate, sessile or amplexicaul, pale green, rigid, brittle, smooth, glabrous; surface minutely dotted; margin coarsely serrate. Flower-heads yellow, hard,

resinous, with several rows of lanceolate-acuminate, recurved bracts. Fruits bi-auriculate or unidentate at the summit, with a pappus consisting of two thick, stiff bristles. All parts more or less resinous. Slightly aromatic odor; taste aromatic and bitter." *Br.*

As it occurs in commerce, grindelia is in the form of the whole dried herb; the stems are about eighteen inches in length, light brownish, very frequently stripped of their leaves, but with some of the floral heads adherent. The brittle leaves are much broken, and, with separate floral heads, are mixed with the stem. The taste is warm, peculiar, and very persistent. Tunmann (*Ph. Zentralh.*, 1908, p. 457) has made an excellent pharmacognostical study of *G. robusta*. Wohn (*Merck's Rep.*, 1910, p. 310) presents the results of a morphological study of *G. squarrosa*. Farwell (*D. C.*, 1907, p. 460) reports having received one of the California "tar weeds," *Hemizouella minima* Gray, for grindelia. The plant is very diminutive in size, but the inflorescence is very glutinous. Perrédès (*P. J.*, 1909, xxix, pp. 596 and 604) gives the results of some experiments in the cultivation of *G. camporum*. The activity of the drug probably resides in the resinous exudation. C. J. Rademaker obtained from it an oil, the odor of which closely resembled that of oil of turpentine, resin, and a crystalline body having an alkaline reaction. (*N. R.*, 1876, p. 205.) W. H. Clark and John L. Fischer (*A. J. P.*, 1888, p. 433) failed to verify all of Rademaker's results, but obtained an alkaline principle to which the name of *grindeline* was given. A. Schneegans (*A. J. P.*, 1892, 369) found in *Grindelia robusta, saponin*, which, he states, is composed of two glucosides; he also found indications of an alkaloid, but believes that its presence is not yet certainly proved. See also *M. R.*, 1898, 394. *Grindelia robusta* is said to contain 0.28 per cent. of a dark-brown essential oil, having a specific gravity of 0.9582 at 15° C. (59° F.), and the optical rotation in alcoholic solution of −8° 08′. It is soluble in ether, amyl alcohol, and chloroform. (*Ph. Ztg.*, 48, 574.)

Uses.—Grindelia is possessed of only feeble physiologic powers, but according to Buffington, when given to the lower animals in very large doses produces narcosis, with dilated pupils, slowing of the action of the heart from stimulation of the inhibitory nerves, and elevation of the blood pressure from stimulation of the vasomotor center. Dobroklowsky has found that it had a primary stimulating and later depressant effect on the isolated frog's heart. He further states that it acts chiefly upon the motor nerves and muscles, but Buffington asserts that it paralyzes first the sensory nerve-trunks, then the sensory side of the spinal cord, and afterwards involves the motor nerve-trunks and cord. Grindelia is used almost solely in the treatment of *bronchial catarrhs*, especially when there is a tendency to *asthma*. Its action is probably simply that of a stimulating expectorant, but some believe it exerts also an antispasmodic influence. It is frequently used in conjunction with stramonium leaves in the preparation of "Asthma powders" or cigarettes. It has been employed with asserted success in *whooping cough*. Its active principles appear to be excreted from the kidneys; hence, after large doses, there are sometimes evidences of renal irritation, and in chronic *catarrh of the bladder* good has been effected by its stimulant influence upon the mucous membrane of the viscus. As a local application, grindelia has been employed with asserted advantage in *burns, vaginitis, genito-urinary catarrh*, etc., applied either in the form of a poultice or in solution. It has considerable use also as a local application in the treatment of *rhus poisoning*. The fluidextract, diluted with water, is employed.

Dose, thirty to forty grains (2.0–2.6 Gm.).

Off. Prep.—Fluidextractum Grindeliæ, *U. S.* (*Br.*).

GUAIACI LIGNUM. Br.

GUAIACUM WOOD

(gwī′ă-cī lĭg′nŭm)

"Guaiacum Wood is the heart-wood of Guaiacum officinale, *Linn.*, or of Guaiacum sanctum, *Linn.*" *Br.* "The heart-wood of *Guaiacum officinale* Linné or of *Guaiacum sanctum* Linné (Fam. *Zygophyllaceæ*)." *N. F.*

Lignum Sanctum (vel Benedictum); Lignum Vitæ; Gayac, *Fr. Cod.*; Bois de Gayac, *Fr.*; Lignum Guajaci, *P. G.*; Guajakholz, Franzosenholz, Pockholz, *G.*; Guajaco, Legno guajaco, *It.*; Guayaco (Leño de), *Sp.*

Guaiacum officinale is a large tree, of a very slow growth. When of full size it is from forty to sixty feet high, with a trunk four or five feet in circumference. The branches are knotted, and covered with an ash-colored striated bark. That of the stem is of a dark-gray color, variegated with greenish or purplish spots. The leaves are opposite, and abruptly pinnate, consisting of two, three, and sometimes four pairs of leaflets, which are obovate, veined, smooth, shining, dark green, from an inch to an inch and a half long, and almost sessile. The flowers are of a rich blue color, stand on long peduncles, and grow to the number of eight or ten at the axils of the upper leaves. The seeds are solitary, hard, and of an oblong shape.

G. sanctum L. is distinguished from *G. officinale* by its five-celled fruit and its oblong or obliquely obovate or sometimes rhomboid-ovate leaflets, six to eight to each leaf. It grows in Cuba, the Bahama Islands and Florida. Its wood is smaller than that of *G. officinale*, and is said by Fée to be paler and less dense.

The commercial supplies are shipped from the Bahama Islands and Florida to London, Hamburg and Havre.

G. officinale grows throughout tropical America, particularly in the Lesser and Greater Antilles, also in Brazil, Venezuela and Colombia. The commercial drug is exported from Port au Prince, Puerto Plata and St. Domingo, also Savanilla (Colombia) and Puerto Cabello (Venezuela). *G. arboreum* of De Candolle has been said to furnish some of the guaiacum wood of commerce.

As imported, guaiac wood is in the shape of logs or billets, covered with thick gray bark, which presents on its inner surface, and upon its edges, when broken, numerous shining crystalline particles. These were supposed by Guibourt to be benzoic acid, by others a resinous exudation from the vessels of the plant; but Otto Berg has determined that they are crystals of calcium sulphate. The billets are used by turners for the fabrication of various instruments and utensils, for which the wood is well adapted by its extreme hardness and density. It is sometimes kept by pharmacists in the state of shavings or raspings, which they obtain from the turners. It is commonly called *lignum vitæ*, a name which obviously originated from its durable properties.

Properties.—Guaiacum wood is hard and heavy. The color of the sap-wood is yellow, that of the older and central layers greenish-brown, that of the shavings a mixture of the two. It is said that when the wood is brought into a state of minute division its color is rendered green by exposure to the air, and bluish-green by the action of nitric acid fumes, and the latter change may be considered as a test of its genuineness. (Duncan.) An easier test is a solution of corrosive sublimate, which, added to the shavings and slightly heated, causes a bluish-green color in the genuine wood. Guaiacum wood is almost without odor unless rubbed or heated, when it becomes odorous. When burned, it emits an agreeable odor. It is bitterish and slightly pungent, but requires to be chewed for some time before the taste is developed.

"Dark greenish-brown, dense, hard; heavier than water. In transverse section, abundant sclerenchymatous fibres, scattered, isolated vessels, and medullary rays one cell wide. Odor, on warming, somewhat aromatic; taste slightly acrid. An alcoholic tincture prepared from the Wood assumes a blue color on the addition of diluted *T. Sol. of ferric chloride.*" *Br.*

The N. F. IV describes it as follows: "Usually in the form of shavings, chips or raspings of a greenish-brown color, heavier than water, entirely free from adhering bark and containing only a few chips or shavings of a whitish color (*sap wood*). Almost odorless except when heated; taste bitter and acrid when chewed for some time. The powder, when examined under the microscope, exhibits numerous fragments of more or less lignified, thick-walled wood fibers, up to 0.028 mm. in width, some with simple, oblique pores; tracheæ from 0.09 to 0.16 mm. in width, some filled with resin; numerous small masses of resin; wood parenchyma and medullary ray cells up to 0.02 mm. in width, with lignified, porous walls and usually containing resin; occasionally tangential views of the medullary rays show an elliptical group of from three to six cells; the resin masses and resinous tissue become bluish-green on the addition of iodine T.S. Place powdered Guaiac Wood in a solution of sodium chloride (1 in 3); the blackish-brown part only will sink and this does not exceed in amount the portion which floats. Shake 10 mils of alcohol with 0.5 Gm. of ground Guaiac Wood for a few seconds and filter the mixture; the filtrate yields a deep blue color with one drop of a solution of ferric chloride (1 in 10). Guaiac Wood yields to alcohol not less than 15 per cent. of extractive. Guaiac Wood yields not more than 3 per cent. of ash." *N. F.*

Guaiac wood contains, according to Trommsdorf, 26 per cent. of resin, and 0.8 of bitter pungent extractive, upon both of which, probably, though chiefly on the former, its medicinal virtues depend. (See *Guaiacum.*) Paetzold (*Schim. Rep.*, 1902, 43) states that the bark of the guaiac tree yields 1 per cent. of a volatile oil, having an exquisite odor. The wood yields its virtues but slightly to water. One pound of the wood afforded to Geiger two ounces of extract.

Uses.—Guaiacum wood possesses no therapeutic powers which are not contained in its resin and the latter is always to be preferred.

Dose, thirty to sixty grains (2.0–3.9 Gm.).

Off. Prep.—Decoctum Sarsaparillæ Compositum, *N. F.*

GUAIACOL. U. S., Br.

GUAIACOL

(guaĭ'ą-cŏl)

"The monomethyl ether [$C_7H_8O_2$ or $C_6H_4(OH)(OCH_3)$ 1:2 = 124.06] of ortho-dihydroxybenzene, obtained from wood-tar creosote or prepared synthetically. Preserve it in well-closed containers, protected from light." *U. S.*

"Guaiacol, $C_7H_8O_2$, may be prepared synthetically or obtained by the fractional distillation of beech tar creosote." *Br.*

Ortho-dioxybenzene-methyl-ester, Methyl-orthodioxybenzene, Methyl-pyrocatechin, Catechol-monomethyl-ether; Gaïacol, *Fr. Cod.*; Guajakol, Brenzcatechin-monomethyl-ester, *G.*; Guajocolo, *It.*; Guayacol, *Sp.*

Preparation.—Guaiacol is the monomethyl ester of the ortho-dioxybenzene known as catechol (pyrocatechin), and can be readily made from this diatomic phenol by methylating with the aid of methyl-sulphuric acid. It is, however, largely obtained from beechwood creosote, of which it constitutes from 60 to 90 per cent. The separation of the diatomic phenols and phenol-ethers from monatomic phenols in a mixture like creosote, is effected in several ways. The compounds formed by baryta with the former are much less soluble than those with the latter, and this is also true of magnesia compounds. Another method is to rub up the creosote with potassium carbonate. Guaiacol and creosol combine to form solid addition compounds, from which the other phenols are washed out with ether or petroleum benzin, when the crystalline mass is decomposed with water and the phenols separated.

Properties.—It is officially described in the United States Pharmacopœia as "a colorless or yellowish, strongly refractive liquid, or a colorless or yellowish, crystalline solid, having an agreeable, aromatic odor. It becomes darker on exposure to light and air. The solid form

when liquefied may remain so for some time, even at a low temperature. One Gm. of Guaiacol dissolves in 53 mils of water and in 0.8 mil of glycerin at 25° C. (77° F.), but separates from the glycerin on the addition of water; miscible with alcohol, chloroform, ether or acetic acid. The specific gravity of liquid Guaiacol is between 1.110 and 1.114 at 25° C. (77° F.). Solid Guaiacol melts at about 28° C. (82.4° F.). Not less than 85 per cent. of Guaiacol distils between 200° and 210° C. (392° and 410° F.). The addition of a drop of ferric chloride T.S. to 10 mils of an alcoholic solution of Guaiacol (1 in 100) produces an immediate blue color, changing to emerald-green, and finally becoming yellowish. Incinerate about 1 Gm. of Guaiacol; not more than 0.1 per cent. of ash remains. Shake 2 mils of liquefied Guaiacol with 4 mils of purified petroleum benzin; the mixture separates on standing into two distinct, clear layers. Permanent turbidity or failure to separate into layers indicates the presence of impurities. One mil of liquefied Guaiacol dissolves in 2 mils of potassium hydroxide solution (15 per cent.), when heated for one minute in boiling water; on cooling, it congeals to a nearly white mass. Much coloration or failure to congeal indicates the presence of impurities. The mass thus obtained forms a clear solution with 20 volumes of distilled water (turbidity indicates *oily hydrocarbons*)." *U. S.*

"A colorless liquid, or colorless crystals melting at about 28° C. (82.4° F.). Characteristic, tarry odor; taste caustic, very pungent. Soluble in 80 parts of *water;* freely soluble in *alcohol* (90 per cent.), in *ether,* in *glycerin,* and in fixed oils. Liquid Guaiacol optically inactive; specific gravity 1.16 to 1.20. Distils between 200° and 205° C. (392°–401° F.). A trace of *T. Sol. of ferric chloride* added to 25 millilitres of a solution (1 in 100) of Guaiacol in *alcohol* (90 per cent.) immediately produces a blue color which changes to emerald-green on the addition of more of the test-solution, and finally becomes yellowish. When liquid Guaiacol is shaken with twice its volume of *petroleum spirit* and allowed to stand, the mixture separates into well-defined layers which do not exhibit permanent turbidity. 1 millilitre of liquid Guaiacol dissolves when warmed with 2 millilitres of an aqueous solution (15 in 100) of *sodium hydroxide;* the nearly white mass which results on cooling yields a clear solution with 25 millilitres of *water* (absence of oily hydrocarbons)." *Br.*

S. Vreven recommended the following method for distinguishing between guaiacol and creosote: A drop of the liquid to be examined, 2 to 3 drops of ether, and 1 or 2 drops each of concentrated nitric and hydrochloric acids are well shaken together in a test tube. The mixture assumes at first a red-brown color, which is particularly evident in the ether layer; but upon spontaneous evaporation, well-formed needle-shaped crystals will separate out if guaiacol is present, the formation of these crystals being facilitated by occasional shaking, whereas in the presence of creosote oily globules only separate. While phenol gives a reaction similar to that of guaiacol, the crystals formed are easily distinguished from the needles produced by the latter. (*Zeit. Oest. Apoth. Ver.,* 1896, 711.)

Uses.—Guaiacol is locally irritant and somewhat anesthetic. Its germicidal power, although inferior to that of creosote, equals or perhaps surpasses phenol. It is absorbed readily, not only from the alimentary canal, but also through the skin. It is eliminated chiefly through the kidneys in combination with sulphuric and glycuronic acids. Although its general physiological action has not been carefully studied, it seems to resemble phenol, although less poisonous. Guaiacol is used internally chiefly as a stimulating expectorant in *phthisis* and *bronchitis.* It has been also largely used by endermic administration as an antipyretic in *pneumonia* and other *fevers,* but is liable to produce dangerous collapse. Locally it is employed for its anesthetic effects in *herpes zoster, eczema, furunculosis,* and similar conditions, and as an antiseptic in *old ulcers,* especially when *tubercular* or *leprous.*

For percutaneous administration from ten to twenty drops are gently rubbed on the abdomen and the surface covered with oiled silk.

Dose, from five to ten minims (0.3–0.6 mil).

Off. Prep.—Petroxolinum Guaiacolis, *N. F.*

GUAIACOLIS CARBONAS. U. S. (Br.)

GUAIACOL CARBONATE Guaiacol. Carb.

(guaĭ'ą-cō-lĭs cär'bo-năs)

"A guaiacol derivative [$(C_7H_7O)_2CO_3$ or $(C_6H_4(OCH_3)O)_2.CO = 274.11$]." *U. S.* "Guaiacol Carbonate, $(C_7H_7O)_2CO_3$, is the carbonic ester of guaiacol. It may be obtained by the interaction of carbonyl chloride with sodium guaiacolate." *Br.*

Guaiacol Carbonas, *Br.,* Duotal; Carbonate de Gaïacol, *Fr.;* Guajacolkarbonat, Kohlensaure-Gaujacyläther, *G.;* Carbonato de guayacol, *Sp.*

Guaiacol carbonate was introduced into the British Pharmacopœia (1914) for the first time.

Properties.—It is officially described as "a crystalline powder, odorless and tasteless or having a slight, aromatic odor and taste. Guaiacol Carbonate is insoluble in water; 1 Gm. dissolves in 60 mils of alcohol, 1 mil of chloroform, and in 18 mils of ether at 25° C. (77° F.); freely soluble in benzene and slightly soluble in glycerin or fixed oils; freely soluble in boiling alcohol. It melts between 83° and 87° C. (181.4° and 188.6° F.). Incinerate 1 Gm. of Guaiacol Carbonate; not more than 0.1 per cent. of ash remains. A saturated alcoholic solution of Guaiacol Carbonate yields no bluish-green color on the addition of ferric chloride T.S. (*free guaiacol*), and is not acid to litmus paper which has been previously moistened with distilled water. One-tenth Gm. of Guaiacol Carbonate dissolves in 2 mils of sulphuric acid without producing more than a faint yellow color (*readily carbonizable impurities*). Heat about 0.5 Gm. of Guaiacol Carbonate for a few minutes with 10 mils of alcoholic potassium hy-

droxide T.S. and cool the mixture; a crystalline precipitate is formed, which effervesces with acids. If the alcohol is evaporated from the filtered liquid, the residue supersaturated with diluted sulphuric acid and shaken out with ether, the separated ether layer, upon spontaneous evaporation of the ether, leaves a residue which responds to the tests for identity under *Guaiacol." U. S.*

"A white crystalline powder, inodorous and almost tasteless. Insoluble in *water;* sparingly soluble in *alcohol* (90 per cent.), the solution being neutral to *litmus.* Melting point 85° to 88° C. (185°–190.4° F.). When the liquid obtained by heating Guaiacol Carbonate with *N/20 solution of sodium hydroxide* is acidified, carbon dioxide is evolved and guaiacol is liberated. A saturated solution in *alcohol* (90 per cent.) does not assume a greenish or bluish color on the addition of *T. Sol. of ferric chloride* (absence of free guaiacol). No appreciable ash." *Br.*

Uses.—Guaiacol carbonate is much used as a substitute for guaiacol on account of its comparative tastelessness and its lack of irritant properties. It is, however, much less active and less effective than is guaiacol, both as a local and systemic drug. The experiments of W. Hesse indicate that when taken internally much of it passes through the alimentary canal unabsorbed.

Dose, from ten to twenty grains (0.65–1.3 Gm.).

GUAIACUM. U. S. (Br.)

GUAIAC Guaiac. [Guaiaci Resina, Pharm. 1890, Guaiac Resin]

(guaĭ'ạ-cŭm)

"The resin of the wood of *Guaiacum officinale* Linné, or of *Guaiacum sanctum* Linné (Fam. *Zygophyllaceæ*)." *U. S.* "Guaiacum Resin is the resin obtained from the stem of Guaiacum officinale, *Linn.,* or of Guaiacum sanctum, *Linn.*" *Br.*

Guaiaci Resina, *Br.,* Guaiacum Resin; Résine de Gayac. *Fr. Cod.;* Resina Guajaci, *P. G.;* Guajak, Guajakharz, *G.;* Resina de guajaco, *It.;* Resina de guayaco, *Sp.*

For a description of *Guaiacum officinale,* see *Guaiaci Lignum,* p. 535.

Guaiac resin was introduced into the London Pharmacopœia in 1677. It exists in the tree as a physiological product filling up the tissues of the wood. It is obtained in several different modes. The most simple is by spontaneous exudation, or by incisions made into the trunk. Another method is by sawing the wood into billets about three feet long, boring them longitudinally with an auger, then placing one end of the billet on the fire, and receiving in a calabash the melted guaiac, which flows out through the hole at the opposite extremity. But the plan probably most frequently pursued is to boil the wood, in the state of chips or sawdust, in a solution of common salt, and skim off the substance which arises to the surface. Guaiac is chiefly produced in the eastern portion of the Island of Haiti, being exported from Port au Prince and Gonaïves. (*Ap.-Ztg.,* xxv, p. 556.) It is estimated that in 1912 about 6000 pounds of guaiac resin were exported to the United States. It is usually in large irregular pieces of various sizes, in which small fragments of bark, sand, and other impurities are mixed with the genuine guaiac, so as to give to the mass a diversified appearance. Sometimes it is found in small roundish homogeneous portions, separate or agglutinated; sometimes in homogeneous masses, prepared by melting and straining the drug in its impure state. It is probable that the guaiac obtained from the billets in the manner above described is of uniform consistence.

Properties.—The masses are irregular or somewhat globular, of a glassy luster and resinous fracture. They are of a deep greenish-brown or dark-olive color on their external surface, and internally wherever the air can penetrate. The predominant hue of those parts not exposed to the air is reddish-brown or hyacinthine, diversified, however, with shades of various colors. The odor is feeble but fragrant, and is rendered stronger by heat. The taste, which is at first scarcely perceptible, becomes acrid after a short period, and a permanent sense of warmth and pungency is left in the mouth and fauces. Guaiac is brittle, and when broken presents a shining glass-like surface, conchoidal or splintery, with smaller fragments more or less translucent. It is readily pulverized, and the powder, at first of a light-gray color, becomes green on exposure to the light. Its sp. gr. varies from 1.2 to 1.23. It softens in the mouth, and melts with a moderate heat. Water dissolves a small proportion of guaiac, not exceeding nine parts in 100, forming an infusion of a greenish-brown color and sweetish taste, which upon evaporation yields a brown substance soluble in hot water and alcohol, but scarcely so in ether. Alcohol takes up the whole, with the exception of impurities. The official requirements are as follows: "In irregular fragments or in large, nearly homogeneous masses, occasionally in more or less rounded or ovoid tears, enclosing fragments of vegetable tissues; externally brown, becoming greenish-gray-brown on exposure, the fractured surface having a glassy luster, the thin pieces being translucent and varying in color from reddish to yellowish-brown; odor balsamic; taste slightly acrid. Guaiac melts between 85° and 90° C. (185° and 194° F.). It is readily soluble in alcohol, ether, chloroform, creosote, and in solutions of the alkalies or in hydrated chloral T.S. It is sparingly soluble in carbon disulphide or benzene and not more than 15 per cent. is insoluble in alcohol; the alcoholic solution, on the addition of an excess of chlorine water or tincture of ferric chloride, becomes blue, changing quickly to green, the color being best seen when the solutions are diluted with an equal volume of water. Macerate the crushed or powdered Guaiac with 4 or 5 times its weight of purified petroleum benzin for three hours and then filter; the filtrate

is colorless, and does not give a green color on the addition of an equal volume of cupric acetate T.S. (*rosin*). The powder is grayish, becoming green on exposure to the air. Guaiac yields not more than 4 per cent. of ash." *U. S.*

"In masses, or sometimes in large more or less rounded tears. Brittle; fracture vitreous; thin splinters transparent, from yellowish-green to reddish-brown. Powdered Resin greyish, but becoming green on exposure to light and air. Odor, on warming, somewhat aromatic; taste slightly acrid. A solution in *alcohol* (90 per cent.) is colored blue by diluted *T. Sol. of ferric chloride.* 1 gramme of the powdered Resin, shaken for five minutes with 5 millilitres of *petroleum spirit,* yields a colorless filtrate which does not become green when shaken with an equal volume of *diluted solution of copper acetate* (absence of colophony). Not more than 10 per cent. insoluble in *alcohol* (90 per cent.). Ash not more than 4 per cent." *Br.*

The tincture is of a deep-brown color, is decomposed by water, and affords blue, green, and brown precipitates with the mineral acids. It is colored blue by nitric acid, by chlorine, and by tincture of ferric chloride, and usually by spirit of nitrous ether, and is similarly changed when treated successively by diluted hydrocyanic acid and solution of copper sulphate. Either in substance or tincture, guaiac gives a blue color to gluten and substances containing it, to mucilage of gum arabic, to milk, and to various freshly cut roots, as to the potato, carrot, and horseradish. This is on account of the fact that oxidizing enzymes or oxidases are present in all of these substances and guaiac resin is one of the most delicate reagents for detecting this class of enzymes. It is soluble also in ether, alkaline solutions, and sulphuric acid. The solution in sulphuric acid is of a rich claret color, deposits, when diluted with water, a lilac precipitate, and, when heated, yields charcoal. Exposed to air and light, guaiac absorbs oxygen and becomes green, and the change takes place rapidly in the sunshine. Schaer states that a good natural guaiac resin is preferable to a resin purified by alcoholic treatment as a reagent, but a solution of resin extracted by chloroform from the wood is the most sensitive of all. Tincture of guaiac has been used for the detection of blood stains, which it does by the blue color produced by it, when in contact with the red coloring matter of blood, in connection with some ozonized substance, especially hydrogen dioxide. R. M. Bertolet (*Am. J. M. S.,* Jan., 1874) has used it to distinguish between the blood of man and other mammals, in which the corpuscles are non-nucleated, from that of other classes, as birds, fishes, and reptiles, which have nucleated corpuscles.

Lücker (*Proc. A. Ph. A.,* 1894, 953), finds in guaiac three acids,—viz., *guaiacic,* $C_{20}H_{24}O_4$, occurring in crystals melting at 86° C. (186.8° F.); *guaiaconic,* $C_{20}H_{24}O_5$, an amorphous body melting at from 81° to 83° C. (177.8°–181.4° F.); and *guaiacinic,* $C_{21}H_{22}O_7$. He considers all three of them to be probably condensation products from tiglic aldehyde with creosol and guaiacol. Döbner has also determined that these three acids form a series of hydroxyl-containing acids which may be represented by the formulas: $C_{20}H_{23}O_3(OH)$, $C_{20}H_{22}O_3(OH)_2$ and $C_{21}H_{19}O_4(OH)_3$. (Tschirch, *Harze und Harzbehälter,* 1900, p. 300.) *Guaiac yellow,* the coloring matter of guaiac resin, was first observed by Pelletier. It crystallizes in pale yellow quadratic octahedra having a bitter taste, but is not a glucoside. Guaiac resin also yields interesting products on dry distillation. First, according to Hlasiwetz, is obtained *guaiacene,* C_5H_8O, at 118° C. (244.4° F.), next *guaiacol,* $C_6H_4\begin{cases}OCH_3\\OH\end{cases}$, being the methyl ether of pyrocatechin, at 205° to 210° C. (401°–410° F.), and with it *kreosol,* $C_6H_3(CH_3)_2OH$, and finally *pyroguaiacin,* $C_{33}H_{44}O_6$ (according to Wiesner, $C_{18}H_{18}O_3$), in pearly scales, melting at 180° C. (356° F.). According to Lieben and Zeisel (*Ber. d. Chem. Ges.,* xiv, p. 932), guaiacene is the aldehyde of tiglic acid, $C_5H_8O_2$, and can be made synthetically from a mixture of acetaldehyde and propionaldehyde. When distilled with zinc dust there is obtained *creosol* (50 per cent. in the case of resin purified by alcohol) and 30 per cent. of a mixture of *toluene, meta-* and *paraxylene,* with a little *pseudocumene* and *guaion,* $C_{12}H_{12}$.

Saponin has been found by E. Paetzold in the bark, the wood, and the natural resin of guaiacum. (*Bull. des Sciences Pharm.,* iii, 407.) According to the experiments of W. Frieboes (*In. Dis.,* Rostock, 1903), this saponin (1 to 1000) forms a frothing solution which is persistent, is an excellent emulsifier, has the power to maintain in solution large proportions of sparingly soluble substances and is innocuous and non-irritant.

The mineral acids are incompatible with the solutions of guaiac.

Adulterations.—This drug is sometimes adulterated with the rosin of the pine. The fraud may be detected by the terebinthinate odor exhaled when the sophisticated guaiac is thrown upon burning coals, as well as by its partial solubility in hot oil of turpentine. This liquid dissolves rosin, but leaves pure guaiac untouched. Amber was said to be another adulterant at one time. Nitric acid affords an excellent test of guaiac. If paper moistened with the tincture be exposed to the fumes of this acid, it speedily becomes blue. Purgotti proposed guaiac resin as a test for copper. (See *A. J. P.,* June, 1880.)

Uses.—Guaiac, like many other resinous substances, is stimulant and alterative. If given to a patient when covered warm in bed, and accompanied with hot drinks, may assist in exciting perspiration, and hence it has been ranked among the diaphoretics. In large doses it purges, and it has been especially commended as a laxative in *chronic rheumatism,* and it is thought by some practitioners to be possessed of emmenagogue powers. It has been given in *chronic rheumatism, gouty affections,* secondary *syphilis, scrofulous diseases,* and *cutaneous eruptions,* but is

of doubtful service. The medicine is given in substance or tincture. The dose of the powder is from ten to thirty grains (0.65–2.0 Gm.), which may be exhibited in pill or bolus, in the shape of an emulsion formed with gum arabic, sugar, and water, or as a syrup. An objection to the form of powder is that it quickly aggregates. Guaiac is sometimes administered in combination with alkalies, with which it readily unites. The ammoniated tincture of guaiac is a preparation of this kind. Several European Pharmacopœias direct a *soap of guaiac,* under the name of *sapo guaiacinus,* to be prepared by diluting solution of potassium hydroxide with twice its weight of water, boiling lightly, then adding guaiac gradually, with continued agitation, so long as it continues to be dissolved, and finally filtering, which was followed by evaporating to the pilular consistence.

T. C. Craig (*A. J. P.,* July, 1880) recommends a *Syrup of Guaiac* made as follows: Powd. Guaiac Resin, 640 grains; Caustic Potassa, 58 grains; White Sugar, 1 lb. (av.); Water, q. s. Dissolve the Potassa in 8 fluidounces of water; moisten the Guaiac with this solution; pack it in a percolator, and gradually pour on the remainder of the solution; when this ceases dropping, add sufficient water to make the percolate measure 8 fluidounces; add the sugar, and dissolve.

Dose, from ten to thirty grains (0.65–2.0 Gm.).

GUARANA. U. S.

GUARANA

(guạ-rā′nạ)

"A dried paste consisting chiefly of the crushed seeds of *Paullinia Cupana* Kunth (Fam. *Sapindaceæ*), yielding not less than 4 per cent. of caffeine." *U. S.*

Paullinia, Brazilian Cocoa, Guarana Bread; Guarana, *Fr. Cod.;* Pasta Guaranæ; Guarana, *G., It.;* Paulinia, Guarana, *Sp.*

There are described of the genus *Paullinia* 121 species, all of them confined in their geographical range to tropical and subtropical South America, except one, which has strayed to Eastern and Western Africa, and two others which are found in Mexico and in the gardens of the Sandwich Islands. The name of the genus was given in honor of Christ. Fred. Paullini, a German medico-botanical writer, who died in 1712.

The *Paullinia Cupana* Kunth is a climbing shrub with alternate compound impari-pinnate leaves, which is native to the Northwestern provinces of Brazil. The flowers are of yellowish color, growing in spicate panicles. The leaves are long petioled, the leaflets being 5 to 6 inches long by 2 or 3 inches wide, and sinuate dentate on the margins. The fruit is ovoid or pyriform and about the size of a grape, and contains 1 to 3 seeds which resemble small horse chestnuts.

It is probable that in the preparation of guarana the seeds of the allied species *P. sorbilis* Martius, are used interchangeably with those of the official species.

The seeds, which look like small horse-chestnuts, are lenticular and almost thorny, and invested with a flesh-colored arillus, which is easily separable when dry. *Guarana* is made exclusively by the Guaranis, a tribe of South America Indians, and probably varies in the details of its preparation, as it certainly does in appearance and quality. The drug appears to be produced almost exclusively from plants cultivated in the region of the lower Madeira and southward. After the seeds are shelled and thoroughly washed they are roasted for about six hours, and their external papery shells are then removed by placing them in sacks and beating them with clubs; or, after the seeds have been broken in a mortar, the coarse powder is mixed with a little water, and then kneaded into a paste, which is shaped into cylindrical or globular masses. The latter are dried, sometimes in the sun, or more usually by the heat of a slow fire so arranged as to avoid smoke. When finished, the masses are of a reddish-brown color, rugose on the surface, very hard, with an irregular fracture, and of a marbled appearance when broken, due to the fragments of the seeds and their black testa embedded in the mass.

Guarana occurs in a number of molded forms, and an excellent collection of these can be found in the Philadelphia Commercial Museum. Stockman (*P. J.,* liii; *P. J.,* lxxxix, p. 685) describes and illustrates some of these interesting forms.

Properties.—It is officially described as follows: "Usually in cylindrical sticks, about 3 to 5 cm. in diameter, externally dark reddish-brown; hard and heavy; fracture uneven, often fissured in the center; internally pale reddish-brown, showing more or less coarse fragments of seeds and occasionally their blackish-brown integuments; odor slight; taste slightly astringent and bitter. The powder is light pinkish-brown; consisting mostly of irregular masses of parenchyma containing more or less altered starch grains; unaltered starch grains occasional, varying from spherical and polygonal to ellipsoidal and broadly ovoid, 0.01 to 0.025 mm. in diameter; occasional fragments with narrow, elongated sclerenchymatous cells; the walls being thick, yellowish and non-lignified. Place on a slide a drop of hydrochloric acid, add about 0.001 Gm. of powdered Guarana, then add a drop of gold chloride T.S. and allow the mixture to stand for a few minutes; beginning at the edge of the mount, crystals of caffeine and gold chloride separate in the form of orthorhombic plates and needles, the latter usually occurring in spheroidal aggregates and finally forming branching groups.

"**Assay.**—Introduce 6 Gm. of Guarana, in No. 60 powder, into a flask and add 120 mils of chloroform and 6 mils of ammonia water. Stopper the flask, shake it frequently for half an hour, then let it stand four hours. Again shake the flask vigorously and when the drug has settled, filter the liquid rapidly through a pledget of purified cotton and collect 100 mils of the filtrate, representing 5 Gm. of Guarana. Evaporate the clear filtrate to dryness and dissolve the residue in weak sulphuric acid with the aid of a gentle heat. When the liquid has cooled, filter it into a separator and wash the container and filter with several small portions of distilled water. Now add ammonia water until the liquid is distinctly alkaline to litmus and shake out the caffeine with chloroform until completely extracted, as shown by testing with iodine T.S. in place of the usual mercuric potassium iodide T.S. Evaporate the united chloroform solutions and dry the residue to constant weight at 80° C. (176° F.). The weight is the amount of caffeine from 5 Gm. of Guarana (see Proximate Assays, Part III)." *U. S.*

Guarana is of a somewhat astringent and bitterish taste, and in this, as well as in its odor, bears some resemblance to chocolate, though not oleaginous. It swells up and softens in water, which partially dissolves it. It is also partly soluble in alcohol. Martius found in it a crystallizable principle, which he named *guaranine*, but which was later proved by Berthemot and Dechastelus to be identical with *caffeine*. Alexander Bennett, in an elaborate series of physiological experiments, confirmed this identity Caffeine may be obtained by microsublimation and Rosenthaler (*B. P. G.*, xxi, p. 532) describes the crystals obtained from guarana by means of pyroanalysis. According to Berthemot and Dechastelus, the caffeine exists in the seeds united with tannic acid, with which it appears to form two compounds, one crystallizable and soluble in water, the other of a resinoid appearance and insoluble. Besides these ingredients the seeds contain free tannic acid, gum, albumen, starch, and a greenish fixed oil. (*J. P. C.*, xxvi, 514.)

M. I. Wilbert (*J. A. Ph. A.*, 1914, 1286) reported a compilation of analyses of guarana comprising 41 samples in which the caffeine content varied from 3.72 to 5.16 per cent.

Rochefontaine and Gusset prepared caffeine by mixing one part of calcined magnesia with five parts of powdered guarana, moistening with water, and, after standing twenty-four hours, exhausting the mass with boiling chloroform, evaporating the chloroform, treating the residue with boiling water, filtering, and evaporating over sulphuric acid. (*A. J. P.*, 1886, p. 248.) F. V. Greene (United States Navy) prefers a process for obtaining caffeine from guarana similar to one proposed by Wayne for its extraction from tea and coffee. See *U. S. D.*, 19th ed., p. 606.

F. V. Greene has shown that the tannic acid from guarana has different properties from that found in other plants, and proposes to call it *paullinitannic acid*. (*A. J. P.*, 1877, 390.) Fournier has found in guarana, besides caffeine tannate, the following principles: gum, starch, an acrid green fixed oil, a concrete volatile oil, an aromatic liquid volatile oil soluble in water with a little alcohol, another liquid volatile oil scarcely soluble in water, a peculiar principle not precisely determined, and tannic acid. (*J. P. C.*, April, 1861, 291.) E. R. Squibb examined commercial guarana, and obtained 4.38 per cent. of alkaloid from good specimens. On account of the uncertainty of the composition of guarana, he recommended physicians to prescribe fluidextract of green coffee in its place. (See *Ephem.*, 1884, 612.)

Uses.—The effects of guarana upon the system are chiefly those of its alkaloid, although it contains enough tannin to have an appreciable influence. It is habitually employed by the Indians, either mixed with articles of diet, as with cassava or chocolate, or in the form of drink, prepared by scraping it, and suspending the powder in sweetened water, precisely as other nations use teas, coffees, etc. It is also considered by the Indians useful in the prevention and cure of bowel complaints. Gavrelle, who was at one time physician to Dom Pedro, in Brazil, and there became acquainted with the virtues of this medicine, called the attention of the profession to it some years since in France. It is now used in medicine almost exclusively to give relief during the paroxysm of *migraine*, and in atonic *chronic diarrhea*, taken three or four times a day.

Dose, of the powder, twenty to sixty grains (1.3–3.9 Gm.); of the fluidextract, twenty to sixty minims (1.3–3.75 mils).

Off. Prep.—Fluidextractum Guaranæ, *U. S.*; Elixir Guaranæ (from Fluidextract), *N. F.*

GUMMI INDICUM. Br.

INDIAN GUM [Ghatti Gum]

(gŭm'mī ĭn'dĭ-cŭm)

"Indian Gum is a gummy exudation from the stem of Anogeissus latifolia, *Wall.*" *Br.*

The genus *Anogeissus* (Fam. *Combretaceæ*) includes four or five different species of tropical trees. Of these *A. latifolia* is widely distributed in Farther India. The tree is large and handsome, and one of the most useful of tropical India. The leaves are broadly elliptical, obtuse at the base and summit. They contain large amounts of tannin and are used in Bombay for tanning. The flowers are axillary and the fruit is 2-winged, being arranged horizontally into dense heads. The gum from this tree is collected in April and is used extensively in calico printing, especially in Lucknow. It is less adhesive than Acacia and is usually used in connection with turmeric with which there is some specific combination.

"In vermiform or rounded tears of varying size, colorless or pale yellow; surface dull, fracture vitreous. Slight odor; taste insipid and

mucilaginous. Entirely soluble in *water,* forming a viscous, adhesive mucilage. Insoluble in *alcohol* (90 per cent.). The aqueous solution is gelatinised by the addition of *alcohol* (90 per cent.), or *solution of lead subacetate;* but it is unaffected by the addition of *T. Sol. of ferric chloride* or of *solution of lead acetate* (distinction from Amrad and certain other gums). It is not colored blue or brown by a small quantity of *N/10 solution of iodine* (absence of starch or commercial dextrin). Ash not more than 4 per cent. In India and the Eastern Divisions of the Empire, Indian Gum may be employed in making the official preparations for which Gum Acacia is directed to be used, one part of the former being taken for every two parts ordered of the latter (see 'Mucilago Gummi Indici')." *Br.*

Uses.—Indian gum is used for the same purposes in pharmacy as acacia. It must not be confounded with the so-called *India Gum* which is only slightly soluble in water. (See p. 3.)

Off. Prep.—Mucilago Gummi Indici, *Br.*

(hæ'mą-tŏx'ȳl-ī lĭg'nŭm)

"Logwood is the heart-wood of Hæmatoxylon campecheanum, *Linn." Br.* "The heart-wood of *Hæmatoxylon campechianum* Linné (Fam. *Leguminosæ*) that has not undergone fermentation." *N. F.*

Hæmatoxylon, *N. F.*; Lignum Campechianum, Lignum Cœruleum; Bois de Campêche ou Bois d'Inde, *Fr. Cod.*; Bois de Sang, *Fr.*; Blauholz, Campecheholz, Blutholz, Kampeschenholz, *G.*

Hæmatoxylon campechianum is a tree of middle size, usually not more than twenty-four feet high, though, under favorable circumstances, it sometimes rises forty or fifty feet. The trunk is often very crooked, and is covered with a dark rough bark. The branches are beset with sharp spines. The sap-wood is yellowish, but the interior layers are of a deep-red color. The leaves are alternate, abruptly pinnate, and composed of three or four pairs of sessile, nearly obcordate, obliquely nerved leaflets. The flowers, which are in axillary spikes or racemes near the ends of the branches, have a brownish-purple calyx and lemon-yellow petals. They exhale an agreeable odor, said to resemble that of the jonquil.

The tree is a native of Campeche, the shores of Honduras Bay, and other parts of tropical America, and has become naturalized in Jamaica. It is cultivated in tropical America and Asia. The wood, which is the part used in medicine, is a valuable article of commerce, and largely employed in dyeing. It comes to us in logs deprived of the sap-wood and having a blackish-brown color externally. It has been estimated that about 400,000,000 pounds of logwood are annually consumed. In 1912 Haiti exported about 83,000,000 pounds of logwood to the United States. (See *A. J. P.,* 1912, p. 86.) According to Louis Siebold, the ground or chipped logwood of commerce is unfit for use as a medicinal agent, because it has been prepared as a dyestuff by being exposed in large moist heaps until its hematoxylin has been converted by oxidation into hematein. As a coloring agent, for commercial purposes, this fermented logwood, according to Siebold, is much superior to the natural wood. An inferior variety of logwood which contains little or no hematoxylin, but a pure yellowish-gray dye is that known as *bastard logwood.* According to the researches of E. S. Earl this bastard logwood is produced by a variety of the species, which, when growing, cannot be distinguished from the ordinary form. (*B. D. A. J.,* i, 31.)

Properties.—Logwood is hard, compact, heavy, of a deep-red color, becoming purplish-black by exposure, internally brown-red, and marked with irregular, concentric circles, splitting irregularly, of a slight peculiar odor, and a sweet, somewhat astringent taste. Logwood is officially described as "Hard, heavy, dull orange to purplish-red externally and reddish-brown internally. In transverse section, alternating yellowish-brown and dark brown wavy tangential lines. In the form of chips or coarse powder, it is free from signs of fermentation, and from green metallic lustre. Slight, agreeable odor; taste sweetish, astringent. Readily imparts a reddish-violet color to *water* made slightly alkaline with *solution of sodium hydroxide." Br.*

The N. F. IV description is as follows: "Usually in small chips, reddish-brown, the freshly cut surface dark yellowish-red; a transverse section of the wood shows medullary rays which are up to four cells wide. Odor faint, agreeable; taste sweetish, astringent. Hematoxylon imparts a yellowish color to water containing a little acid, the color being changed to purple or violet-red by alkalies. The powder is reddish-brown and, when examined under the microscope, exhibits medullary ray cells in one to seven rows; wood fibers, long, with thickened walls; wood parenchyma with occasional crystals of calcium oxalate; tracheæ from 0.09 to 0.17 mm. in width; walls of the cells colored brownish-red, the inner cells containing resin masses. Hematoxylon yields not more than 3.5 per cent. of ash." *N. F.*

Its solution affords precipitates with sulphuric, nitric, hydrochloric, and acetic acids, alum, copper sulphate, lead acetate, and ferrous sulphate, striking a bluish-black color with the last mentioned salt. Precipitates are also produced with it by lime water and gelatin. Chevreul found in logwood a volatile oil, an oleaginous or resinous matter, a brown substance the solution of which is precipitated by gelatin (*tannin*), another brown substance soluble in alcohol but insoluble in water or ether, a nitrogenous substance resembling gluten, free acetic acid, various salts, and a peculiar principle called *hæmatoxylin* or *hæmatin* (which must not be confused with the hæmatin of the blood), on which the coloring properties of the wood depend. This is ob-

tained by digesting the aqueous extract in alcohol, evaporating the tincture until it thickens, then adding a little water, and submitting the liquid to a new but gentle evaporation. Upon allowing it to rest, hematoxylin is deposited in crystals, which may be purified by washing with alcohol and drying. Thus procured, the crystals are shining, of a yellowish-rose color, bitterish, acrid, and slightly astringent to the taste, readily soluble in boiling water, forming an orange-red solution which becomes yellow on cooling, and soluble also in alcohol and ether. According to Erdmann, who obtained hematoxylin by the process of Chevreul, substituting ether for alcohol, its crystals, when quite pure, are colorless, without a tinge of redness; its taste is sweet, like that of licorice, without bitterness or astringency; and it is not of itself a coloring substance, but affords beautiful red, blue, and purple colors, by the joint action of an alkaline base and the oxygen of the air. He obtained from logwood 9 to 12 per cent. of crystallized hematoxylin, to which he gave the formula $C_{16}H_{14}O_6$. It crystallizes with 1 or with 3 molecules of water, and is readily soluble in hot water or alcohol, but sparingly in cold water or in ether. (*J. Pr. Chem.*, xxxvi, p. 205.) By the combined action of ammonia and oxygen dark violet crystalline scales of *hematein*, $C_{16}H_{12}O_6 + 3H_2O$, are produced. They show a fine green hue, which is also very commonly observable on the surface of the logwood chips of commerce. Hematein may again be transformed into hematoxylin by means of nascent hydrogen or of sulphurous acid. Commercial extract of logwood extracted from the wood by boiling water contains both hematoxylin and hematein. Hematoxylin, in alcoholic solution, is used as an indicator in the U. S. P. IX. (See Hematoxylin Test-solution, Part III.)

Uses.—Logwood is a mild astringent, devoid of irritating properties, and well adapted to the treatment of that relaxed condition of bowels which is apt to succeed *cholera infantum*. It is also occasionally used with advantage in ordinary *chronic diarrhea* and *chronic dysentery*. *Hematoxylin* was found by Combemale (*B. M. N.*, xxxiii, 1894) to be very feebly antiseptic, but capable in large doses of producing fatal gastro-enteritis in the lower animals. It is used not only as a dye-stuff but also as a microscopical stain.

Dose, from ten to thirty grains (0.65–1.9 Gm.).

HAMAMELIDIS CORTEX. Br.

HAMAMELIS BARK [Witchhazel Bark]

(hăm-ą-mĕl'ĭ-dĭs cŏr'tĕx)

"Hamamelis Bark is the dried bark of Hamamelis virginiana, *Linn.*" *Br.*

Hamamelidis Cortex, *U. S. VIII*, Witchhazel, Spotted Hazel, Snapping Hazel, Winterbloom; Ecorce de Hamamelis, *Fr. Cod.*; Hamamelis, Zauberhasel, *G.*; Hamamelis, *Sp.*

This bark was deleted from the U. S. P. IX, but retained by the British Pharm., 1914. The U. S. P. VIII definition was as follows: "The bark and twigs of *Hamamelis virginiana* Linné (Fam. *Hamameliadaceæ*)."

Witchhazel is an indigenous shrub, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and often on the banks of streams. It is the only species of the genus found in Eastern North America, occurring from New Brunswick to Minnesota and southward to Florida and Texas. Schneider asserts that it has been introduced into California and that it is extensively cultivated in this locality. It is specifically characterized by its leaves being obovate or oval, wavy-toothed, and somewhat downy when young. The seeds are black and shining externally, white, oily, and farinaceous within, and edible like the hazelnut. It is remarkable for the late appearance of its yellow flowers, which expand in September or October, and continue until the weather becomes very cold in winter. The fruit, which is a nut-like capsule not unlike the hazelnut, ripens in the following summer, and is often mingled on the same plant with the new blossoms.

Properties.—The bark occurs "in curved or channelled pieces about one and a half millimetres thick, and from one-half to two decimetres long, sometimes covered with a silvery-grey or dark-grey scaly cork marked with transverse lenticels, but frequently freed from the cork, and then exhibiting a nearly smooth reddish-brown outer surface. Inner surface pale reddish-pink, and finely striated longitudinally; fracture laminated and coarsely fibrous. In transverse section, a cortex containing prismatic crystals of calcium oxalate, a complete ring of sclerenchymatous cells, and numerous tangentially elongated groups of bast fibres. No marked odor; taste astringent." *Br.*

The twigs are "flexible and tough, of irregular length, not more than 6 Mm. in diameter, branching, or bearing nodes at intervals of 2 to 5 Cm.; externally varying from yellowish-brown to deep purplish-brown, lightly longitudinally wrinkled, and having scattered small circular whitish or pale lenticels; bark occupying about one-fifth of the radius; wood greenish-white, lightly radiate, and exhibiting one to three annual rings; pith centric, small." *U. S. VIII.*

Holm (*Merck's Rep.*, xxi, p. 5) has written an illustrated paper on the morphology of hamamelis.

Walter B. Cheney examined witchhazel bark, and found tannin, resin, extractive, but no indication of an alkaloid or other crystalline principle. (*A. J. P.*, 1886, p. 418.) It contains a trace of volatile oil, however. John Marshall, of the University of Pennsylvania, also found that hamamelis root contains tannic acid and a trace of volatile oil, but no other active substance. (*T. G.*, ii, 295.)

Uses.—The bark of the witchhazel is said to have first attracted attention on account of its

use by the North American Indians as a sedative application to external inflammations. It was many years ago recommended by James Fountain and N. S. Davis (*N. Y. M. J.*, x, 208; *Trans. Amer. Med. Assoc.*, i, 350) in *hemorrhage* of the *lungs* and *stomach*. Professional attention was strongly directed to the remedy on account of the enormous sale of a much vaunted proprietary remedy said to be made by distilling the bark with very dilute alcohol (six per cent.), and used externally for *sprains* and *bruises*, and internally for most of the diseases to which flesh is heir. The pecuniary success of this remedy probably depended in very small part upon the virtues of the witchhazel, which seems to possess no active physiological properties. At least we have injected a very concentrated distillate in large quantities into frogs and into mammals without perceiving any more effects than would be produced by the injection of similar quantities of distilled water, and Guy, in Paris, has reached similar conclusions. This preparation has been so largely used that it has been widely replaced by a similar preparation officially known as *Aqua Hamamelidis*, which see. The fluidextract of the drug is a mild astringent and has been especially recommended in *varicose veins* and *hemorrhoids*. The dose of the fluidextract given ordinarily is a teaspoonful (3.75 mils) four times a day. It may, however, be given in double the quantity with impunity and probably in such doses is an advantageous astringent.

Dose, of leaves or of bark, thirty grains (2 Gm.).

HAMAMELIDIS FOLIA. Br.

HAMAMELIS LEAVES [Hamamelis, U. S. 1890 Witchhazel Leaves]

(hăm-ą-mēl'ĭ-dĭs fō'lĭ-ą)

"Hamamelis Leaves are the fresh or dried leaves of Hamamelis virginiana, *Linn.*" *Br.* "The dried leaves of *Hamamelis virginiana* Linné (Fam. *Hamamelidaceæ*), collected in autumn before the flowering of the plants, and without the presence of more than 10 per cent. of stems or other foreign matter." *N. F.*

Hamamelidis Folia, *N. F.*; Feuilles de Hamamelis, *Fr. Cod.*; Witchhazel, Witch Hazel Leaves.

These leaves were deleted from the U. S. P. IX, but were retained in the British Pharm., 1914, and National Formulary IV.

The National Formulary IV added the following to the U. S. P. VIII definition: "Before the flowering of the plants and without the presence of more than 10 per cent. of stems or other foreign matter."

The British Pharm., 1914, describes the leaves as follows: "Broadly oval in outline, from seven to fifteen centimeters long. Upper surface dark green or brownish-green, under surface paler; apex obtuse, margin sinuate; narrowed towards the base, oblique, slightly cordate, and shortly petiolate. Veins pinnate and prominent on the under surface, where they are furnished with stellate hairs. No marked odor; taste astringent and slightly bitter." *Br.*

The N. F. IV description is as follows: "Petioles from 1 to 1.5 cm. in length; laminæ when entire broadly elliptical or rhomboid-ovate, usually inequilateral, mostly from 8 to 12 cm. in length; summits usually acute, sometimes rounded or acuminate; bases slightly heart-shaped and oblique; margins sinuate or sinuate-dentate; upper surfaces pale or brownish-green, occasionally dark brown with a few stiff, straight hairs; lower surfaces lighter in color, somewhat hairy, midrib and veins prominent. Odor slight; taste astringent, slightly aromatic and bitter. Transverse sections show in addition to the epidermal layers, a palisade layer consisting of a single row of cells and a dorsal pneumatic tissue made up of three to six rows of strongly branching cells; large collateral, fibro-vascular bundles occur in the midrib and petiole, the tracheæ narrow, mostly spiral and associated with numerous narrow, strongly lignified and porous wood fibers; around the phloem occurs a nearly continuous circle of bast fibers, possessing strongly lignified walls; calcium oxalate in monoclinic prisms, from 0.01 to 0.035 mm. in diameter, either in the cells of the mesophyll or in crystal fibers associated with the bast fibers. Under the microscope, surface sections of Hamamelis Leaves show upon the lower surface narrow elliptical stomata, about 0.015 mm. in length and with two to four neighboring cells; from both surfaces, but especially from the under surface, arise stellate hairs composed of from four to twelve cells united at the base, the individual cells being from 0.02 to 0.075 mm. in length, either straight or more or less bent and with very thick walls and narrow lumina, the latter sometimes only apparent in the lower portion of the cells. Hamamelis Leaves yield not more than 6 per cent. of ash." *N. F.*

The microscopical characteristics of the hamamelis leaves have been described by Hans Kramer in *B. P. G.*, xvii, p. 323.

See *Hamamelidis Cortex*.

HEXAMETHYLENAMINA. U. S. (Br.)

HEXAMETHYLENAMINE Hexam. [Hexamethylenetetramine]

(hĕx-ą-mĕ-thȳl-ēn-ą-mī'nȧ)

"A condensation product of ammonia and formaldehyde, hexamethylene-tetramine [$(CH_2)_6N_4 = 140.14$]. Preserve it in well-closed containers." *U. S.* "Hexamine may be obtained by the interaction of ammonia with formic aldehyde. It contains not less than 98 per cent. of pure hexamethylenetetramine, $C_6H_{12}N_4$." *Br.*

Hexamina, *Br.*; Urotropine, Urotropin, Cystogen, Formin, Aminoform, Cystamine, Uritone.

The full name of this compound is hexamethylenetetramine, which was originally used by Nicolaier; the Latin title was shortened upon its admission to the U. S. P. VIII to *Hexamethylenamina,* and in U. S. P. IX abbreviated to "Hexam."; the British Pharm. (1914) adopted the name "Hexamina."

Preparation.—Hexamethylenamine may be made by the gradual addition of 70 parts of stronger ammonia water to 100 parts of a forty per cent. solution of formaldehyde which must be kept well cooled. The ammonia water must be added carefully in small quantities until in slight excess, which is indicated by its odor remaining after the liquid has stood several hours; then ten parts of ammonia water are added and the solution allowed to stand until crystallization is completed. The hexamethylenamine is purified by treatment with animal charcoal and recrystallization.

Properties.—It is officially described as in "colorless, lustrous, odorless crystals, or as a white, crystalline powder. One Gm. of Hexamethylenamine dissolves in 1.5 mils of water, 12.5 mils of alcohol and in 320 mils of ether at 25° C. (77° F.); soluble in chloroform. Its aqueous solution is alkaline to litmus. At about 263° C. (505.4° F.) it sublimes without melting and with partial decomposition, emitting a disagreeable odor. Heat an aqueous solution (1 in 10) with diluted sulphuric acid; it decomposes with the liberation of formaldehyde (recognized by its poor or by its darkening paper moistened with silver ammonium nitrate T.S.). When an aqueous solution (1 in 10) is heated with diluted sulphuric acid and then supersaturated with solution of sodium hydroxide, ammonia is liberated. Incinerate 2 Gm. of Hexamethylenamine; not more than 0.05 per cent. of ash remains. An aqueous solution of Hexamethylenamine (1 in 50) does not become colored or turbid when mixed with an equal volume of hydrogen sulphide T.S. (*heavy metals*). Separate portions of 10 mils each of an aqueous solution of Hexamethylenamine (1 in 50), acidulated with 5 drops of nitric acid, are not rendered turbid by a few drops of barium chloride T.S. (*sulphate*) nor more than slightly opalescent by a few drops of silver nitrate T.S. (*chloride*). Add 1 mil of alkaline mercuric potassium iodide T.S. to 10 mils of an aqueous solution of Hexamethylenamine (1 in 20); no other color is produced than that which results from the addition of the same amount of the reagent to 10 mils of distilled water (*ammonium salts*)." *U. S.*

"Colorless crystals or crystalline powder. Inodorous; taste at first sweetish, afterwards bitter. Soluble in 1.5 parts of *water,* and in 8 parts of *alcohol* (90 per cent.). The aqueous solution is alkaline to *litmus.* When heated to 263° C. (505.4° F.), it sublimes without fusing, and partially decomposes. When heated with *diluted sulphuric acid* formic aldehyde is evolved, and when the solution is cooled and made alkaline with *solution of sodium hydroxide* ammonia is liberated. 0.1 gramme warmed with 5 millilitres of *sulphuric acid* and 0.1 gramme of *salicylic acid* develops a carmine color. A solution of 1 gramme in *water,* mixed with 35 millilitres of *N/1 solution of sulphuric acid,* evaporated on a water-bath until the odor of formaldehyde has disappeared, requires for neutralisation not more than 7 millilitres of *N/1 solution of sodium hydroxide, solution of methyl orange* being used as indicator. No appreciable ash." *Br.*

Hexamethylenamine is slightly hydrolyzed, even by water, with the liberation of ammonia by the following reaction:

$$(CH_2)_6N_4 + 6H_2O = 4NH_3 + 6CH_2O.$$

This decomposition is prevented or diminished by the presence of alkalies and is increased by the presence of acids. Being a rather strong base hexamethylenamine combines with acids to form salts and it has the effect of decomposing salts of alkalies weaker than itself and thus liberates NH_3 from ammonium salts.

It frequently becomes necessary to test for the presence of hexamethylamine in differentiation from formaldehyde. The best test for this purpose is bromine water which gives an orange precipitate when added to aqueous solutions containing even minute traces of hexamethylamine. No precipitate or reaction is produced under these conditions with formaldehyde. This test is applicable directly to urine, but not to body fluids, because of the interfering effect of the proteins therein contained.

If the bromine water test is not directly applicable the fluid is tested for formaldehyde before and after distillation with sulphuric acid. The best test for formaldehyde under such conditions is that of Rimini (*Ann. di Farm.,* 1891, xvii, 97) and is applied as follows: To 10 mils of the fluid to be tested are added in rapid succession, agitating after each addition, the following reagents in the prescribed amounts: 3 drops of a 0.5 per cent. aqueous solution of phenylhydrazine hydrochloride, 2 drops of a 0.5 per cent. aqueous solution of sodium nitroprusside and 3 drops (or a slight excess) of a 15 per cent. aqueous solution of sodium hydroxide. In the presence of formaldehyde even in amounts as small as 1 in 1,000,000, a fugitive green or blue color is produced which quickly changes to yellow and finally to yellowish-red. In the absence of formaldehyde no shade of green or blue is observed when the sodium hydroxide is added.

Uses.—Locally hexamethylenamine is mildly irritant and feebly antiseptic. It is absorbed rapidly from the alimentary tract and circulates in the blood unchanged. Although the greater part is eliminated through the kidneys it has been detected in practically every secretion of the body. After it has passed through the kidney if the urine be, as it normally is, acid in reaction, the hexamethylenamine is slowly broken up with the liberation of formaldehyde. The rapidity of its decomposition appears to be in direct proportion to the degree of acidity

and there is strong evidence that when the urine is alkaline it remains in the bladder unchanged. Although originally introduced as a solvent for uric acid, hexamethylenamine is today used almost exclusively for its antiseptic action, especially in *cystitis.* When the bladder is infected by organisms which cause alkalization of the urine the drug is of little influence —since its effects depend almost entirely on the liberation of formaldehyde—unless the urine can be rendered acid. On the other hand in the cystitis due to typhoid bacillus or whenever the urine is acid, it is probably the most efficient urinary antiseptic we possess. It has also been employed with apparent benefit to prevent infections of the kidney in *scarlatina* and other infectious diseases, although its mode of action in these conditions is not evident.

In 1908 Crowe (*A. I. P. T.,* 1908, xviii, p. 315) demonstrated the appearance of hexamethylenamine in the bile and reported three cases of *cholecystitis* in which the bile became practically sterile after its administration. Although Hanzlik (*J. A. M. A.,* 1914, lxii, p. 295) disputes these conclusions and asserts that on account of the alkalinity of the bile the drug cannot act as an antiseptic in the gall bladder, there is considerable evidence as to its value as a preventative against *gall-stones* and curative of various infections of the bile passages. Miller, in 1911, used it with good results in the treatment of *acute coryza,* and Eisenberg (*J. A. M. A.,* 1912, June 29), in *acute bronchitis.* Despite the theoretical objections which have been urged against this treatment the clinical evidence of its value in those various respiratory infections commonly called *colds,* is too strong to be denied. In our experience, if used within twenty-four hours after the onset of symptoms, about 75 per cent. of the cases can be completely aborted. It has also been suggested for its influence in preventing the growth of germs in the cerebro-spinal fluid, as in *meningitis* and *poliomyelitis,* but its usefulness in these conditions has not been established.

If, as seems at present probable, the value of hexamethylenamine depends upon the liberation of formaldehyde, it is evident that it must be used in sufficiently large doses to form an antiseptic quantity of this reagent. Hinman (*J. A. M. A.,* 1913, lxi, p. 1601), as the result of experimental studies, reaches the conclusion that on account of the fact that some of the drug escapes decomposition, at least forty-five grains (3 Gm.) a day are required in *cystitis.* There are a number of persons who are unable to take such doses on account of the local irritant effect of the drug on the genito-urinary tract. A number of cases of hemorrhagic cystitis have been reported from the use of too large doses of hexamethylenamine.

Not only are there a large number of compounds of hexamethylenamine upon the market, but the official drug is sold under an almost innumerable number of trade names. The compounds of hexamethylenamine are considered in Part II.

An interesting and novel use of hexamethylenamine is afforded by its ready inflammability, and the fact that it burns with a smokeless flame. In the absence of a bunsen burner or an alcohol lamp, a five grain tablet of hexamethylenamine placed upon a metal or other non-inflammable surface and ignited will develop enough heat and for a long enough time to boil a test tube full of liquid, as in making a test for albumen in urine.

Dose, five to twenty grains (0.32–1.3 Gm.).

HIRUDO. Br.

LEECHES

(hĭ-rū′dō)

"Leeches are (1) Hirudo medicinalis, *Linn.,* the Speckled Leech, and (2) Hirudo quinquestriata, *Schmarda,* the Five-striped or Australian Leech." *Br.*

Sangsue médicinale, *Fr. Cod.;* Hirudines, *P. G.;* Blutegel, *G.* Sanguisuga, Mignatta, *It.;* Sanguijuela, *Sp.*

Leeches are highly specialized *Annelides.* This class contains the worms with red blood, having soft retractile bodies composed of numerous segments or rings, breathing generally by means of branchiæ, with a nervous system consisting in a double knotted cord, destitute of feet, and supplying their place by the contractile power of their segments or rings. There are three classes of leeches, depending upon their habits. (1) Temporary parasites which include most of this group of animals and are found in cold seas. (2) A class of nearly permanent parasites which are found in both temperate and tropical regions. (3) A class of of predatory hunters or scavengers which are confined to warm regions. These classes may change from one mode of life to another. Four families are usually distinguished and commonly designated as fish leeches; tortoise and snail leeches; worm leeches; and jawed leeches. The latter include the *Hirudinidæ,* which are distinguished in that they have no proboscis and generally possess three-toothed jaws. The true blood-sucking leeches, the medicinal leech of Europe, belong to this group.

The leech is an aquatic worm with a flattened body, tapering towards each end, and terminating in circular flattened disks, the hinder one being the larger of the two. It swims with a vertical undulating motion, and moves when out of the water by means of these disks or suckers, fastening itself first by one and then by the other, and alternately stretching out and contracting its body. The mouth is placed in the center of the anterior disk, and is furnished with three cartilaginous jaws at the entrance of the alimentary canal. These jaws are lined at their edges with fine sharp teeth, and meet so as to make a triangular incision in the flesh. The head is furnished with small raised points, supposed by some to be eyes. Respiration is carried on through small apertures ranged along the inferior surface. The nervous system consists of a cord extending the whole length, furnished with numerous gan-

glions. The intestinal canal is straight, and terminates in the anus, near the posterior disk. Leeches are hermaphrodite, and mutually impregnate each other. They are oviparous; and the eggs, varying from six to fifteen, are contained in a sort of spongy, slimy cocoon, from half an inch to an inch in diameter. These are deposited near the edge of the water, and hatched by the heat of the sun. The leech is torpid during the winter, and casts off from time to time a thick slimy coating from its skin. It can live a considerable time in sphagnous moss or in moistened earth, and is frequently transported in this manner to great distances without injury.

Savigny has divided the genus *Hirudo* of Linnæus into several genera. The true leech is the *Sanguisuga* of this author, and is characterized by its three lenticular jaws, each armed with two rows of teeth, and by having ten ocular points. Several species are used for medicinal purposes, of which the most common are the gray and the green leech of Europe, both of which are varieties of the *Hirudo medicinalis* of Linnæus, and the *Hirudo decora* of this country.

The British Pharm. (1914) gives the following description: "Body soft, smooth, five centimetres or more long, tapering to each extremity, plano-convex, marked with from ninety to one hundred fine annulations. Anterior extremity terminated by a small sucker surrounding the tri-radiate jaws, the posterior extremity by a large sucker. (1) Speckled Leech: dorsal surface olive-green, with six longitudinal stripes; ventral surface greenish-yellow, with black spots. (2) Five-striped Leech: dorsal surface greenish-brown, with five longitudinal stripes; ventral surface greenish-yellow, not spotted." *Br.*

1. *Hirudo medicinalis* Linn. (*Sanguisuga officinalis* Savigny). *The green* or *gray leech.*—This leech is marked with six longitudinal dorsal ferruginous stripes, the four lateral ones being interrupted or tessellated with black spots. The color of the back varies from a blackish to a grayish-green. The belly in the one variety is of a yellowish-green color, free from spots, and bordered with longitudinal black stripes. In the second variety it is of a green color, bordered and maculated with black. This leech varies from two to four inches in length. It inhabits marshes and running streams, and is abundant throughout Europe. A variety of the leech has come into use in Europe, called in commerce, *African leeches.* They are of a beautiful light-green color, varying to a deep green, and often inclining to red, with black points on the back, and broad streaks of a bright orange yellow, which are black towards the abdomen. They correspond perfectly with the *Sanguisuga interrupta* of Moquin-Tandon. These leeches draw very well. (*P. J.*, x, 38.) The leeches from Algiers, called in French commerce, *dragons* (*Sanguisuga troctena* of Moquin-Tandon), of which considerable numbers have been taken to France, are said by M. A. de Quatrefages, contrary to former opinion, to be quite equal to the European. (*J. P. C.*, 3e sér., xxxiii.)

2. *Macrobdella* (*Hirudo*) *decora* Say, the medicinal leech of America, has a back of a deep pistachio-green color, with three longitudinal rows of square spots. These spots are placed on every fifth ring, and are twenty-two in number. The lateral rows of spots are black, and the middle range of a light brownish-orange color. The belly is of the latter color, variously and irregularly spotted with black. The American leech sometimes attains the length of four or five inches, although its usual length is from two to three. It does not make so large and deep an incision as the European leech, and draws less blood. *Hirudo quinquestriata* Schmarda (*Hirudo australis* Bosisto; *Limnobdella quinquestriata* R. Blanch), the *five-striped* or *Australian leech,* has a dorsal surface greenish-yellow-brown, with five longitudinal stripes, the ventral surface being greenish-yellow and not spotted. The jaws are large, with forty-eight to fifty teeth, the inner being the larger.

The great use made of leeches in the practice of medicine has occasioned them to become a considerable article of commerce. They are collected in Spain, France, Italy, Germany, and Sweden, and carried in large numbers to London and Paris. They are also frequently brought to this country, as the practitioners in some of our large cities use only the foreign leeches, although our own waters furnish an inexhaustible supply. The indigenous leech was formerly much used in the city of Philadelphia.

Attempts were made, in France, on a large scale, to propagate leeches for sale. This was done by means of natural meadows, in which numerous small ponds were made, where the leeches, with certain cautions as to nourishment and preservation, multiplied and grew so rapidly as to become a source of profit. In order that they may propagate, it is necessary that they should be fed on blood, which is given them either by causing animals, as horses, cows, etc., to be driven into the meadows, or by obtaining blood from slaughter houses, and, after depriving it of fibrin by agitation, immersing the animals for a time in it while the blood is yet warm.

The proper preservation of leeches is an object of importance, as they are liable to a great and sudden mortality. They are usually kept in jars, in clear, soft water, which should be changed twice a week in winter and every other day in summer. The jar must be covered with a linen cloth, and placed in a situation not liable to sudden changes of temperature. They will live a long time and continue active and healthy without any other attention than that of frequently changing the water in which they are kept. Derheims has proposed the following excellent method of preserving them. In the bottom of a large basin or trough of marble he places a bed, six or seven inches deep, of a mixture of moss, turf, and fragments of wood. He strews pebbles above, so as to retain them in their place without compressing them

too much or preventing the water from freely penetrating them. At one end of the trough, and about midway of its height, is placed a thin slab of marble or earthenware, pierced with numerous holes, and covered with a bed of moss, which is compressed by a thick layer of pebbles. The reservoir being thus disposed is half filled with water, so that the moss and pebbles on the shelf shall be kept constantly moist. The basin is protected from the light by a linen cover stretched over it. By this arrangement the natural habits of the leech are not counteracted. One of these habits, essential to its health, is that of drawing itself through the moss and roots to clear its body from the slimy coat which forms on its skin and is a principal cause of its disease and death. James Banes recommends that when kept in jars they should be cleansed by means of a whisk of very fine broom or willow, when the water is changed. Lahache, an apothecary at Bruyères, strongly recommends carrageen, or Irish moss (*Chondrus crispus*), as admirably adapted to the habits and wants of the leech, furnishing the animal, he supposes, with nutriment, as it does not die of inanition when thus kept. The water should be renewed in the jars daily. (*J. P. C.*, 4e sér., iii, 128.) Alfred Allchin keeps them in aquaria with growing water-plants and snails, which keep the water pure. For other methods of keeping leeches, also of raising them, see *U. S. D.*, 14th ed., 472.

Uses.—Leeches afford the least painful and in many instances the most effectual means for the local abstraction of blood. They are often applicable to parts which, either from their situation or from their great tenderness when inflamed, do not admit of the use of cups, and in the case of infants are under all circumstances preferable to that instrument. They are indeed a powerful therapeutic agent, and give to the physician, in many instances, a control over disease which he could obtain in no other way.

In applying leeches to the skin, care should be taken to shave off the hair, if there be any, and to have the part well cleansed with soap and water, and afterwards with pure water. If the leech does not bite readily, the skin should be moistened with a little blood, or milk and water. It is said to bite more freely if the skin has been previously reddened by a sinapism and then washed perfectly clean. Sometimes the leech is put into a large quill open at both ends, and applied with the head to the skin until it fastens itself, when the quill is withdrawn. If it be desirable that the leech shall bite in a particular spot, this end may be attained by cutting a small hole in a piece of blotting paper, and then applying this moistened to the skin, so that the hole shall be immediately over the spot from which the blood is to be taken. Leeches continue to draw blood until they are gorged, when they drop off. The quantity of blood which they draw varies with the part to which they are applied, and the degree of inflammation existing in it. From the loose and vascular textures they will abstract more than from those which are firm and compact, and more from an inflamed than from a healthy part. As a very efficient mode of applying leeches, it is recommended, after having moistened the skin with pure warm water, to put the leeches into a tumbler half full of cold water, and by an adroit movement invert it upon the part. The leeches are said to attach themselves so rapidly that it seems to the patient as though they made but a single bite. When they are all attached, the glass is to be carefully removed, the water being absorbed, as it runs off on one side, by a sponge or linen cloths. As a rule, our leechers apply six for every fluidounce of blood. A single European leech will draw from half an ounce to an ounce. The quantity may often be much increased by bathing the wound with warm water. Leeches will continue to suck after their tails are cut off, which is sometimes done, although it is a barbarous practice. They may be separated from the skin at any time by sprinkling a little salt upon them. After they drop off, the same application will make them disgorge the blood they have swallowed. Under the name of *bdellotomy*, a practice has been introduced into Germany, of making a small incision in the side of the leech while drawing. The blood escapes through the wound, and the animal will continue to suck for a long time, so that one will perform the office of many in the quantity of blood taken. The practice of using over again leeches which have been made to disgorge the blood they have sucked is to be condemned on account of the danger of carrying infection from one patient to another. In cases where the bleeding from leech bites continues longer than is desirable, it may be stopped by continued pressure, with the application of lint, by the use of collodium, or by touching the wounds with lunar caustic. A little cotton, impregnated with a saturated solution of alum in boiling hot water, and, after it has become sufficiently cool, but before the alum has begun to crystallize, pressed upon the wound, will often prove effectual. If lunar caustic be applied, the stick must first be brought to a fine point, which is to be inserted in the wound hot. When the part wounded is without a bony basis, pressure may be made by pinching the wound between the fingers. It may sometimes be necessary, in the case of a deep bite, to sew the wound, which is readily done with a single stitch of the needle, that need not penetrate deeper than the cutis.

In 1884 Haycraft showed that the saliva of the leech prevented the coagulation of the blood. This is due to the action of a secondary albumose known as *herudin* (*hirudin* is a commercial name for a preparation manufactured from leech heads the precise nature of which is not revealed). Although Rimann and Wolff found that it required twenty milligrammes to render one hundred grammes of human blood non-coagulable, Satterlee and Hooker found that as small an amount as three and a half milli-

grammes per hundred grammes, caused perceptible retardation of clotting. The anticoagulant properties of leech extract, or its active principle, have been of much value in the physiological laboratory. Leech extract may be prepared according to the following method which is a modification of that suggested by Franz: cut off the leech heads, mince them, rub up with a very fine sand, add to the mass 5 mils of physiological salt solution for each leech head and heat for 20 minutes at a temperature of 100° C. (212° F.), allow to macerate for twelve hours, decant off the liquid, wash the sand several times with physiological salt solution, unite the liquids and filter through cheesecloth. This solution, which is suitable for some laboratory purposes, is not gaged by the quantity of solution, but by the number of leech-heads represented. According to Franz, it requires three leeches per kilo body weight to prevent coagulation of the blood in the dog. Preference to-day, however, is generally given to hirudin. This has been used not only in physiological laboratory, but in clinical medicine for the purpose of preventing clotting during transfusion of blood. Marshall (*J. P. Ex. T.*, 1915, vii, 157) has found that commercial samples of hirudin may be highly toxic, apparently from contamination with some product of putrefaction. (For details of technique and extensive literature on the whole subject see article of Satterlee and Hooker, *J. A. M. A.*, 1914, lxii, p. 1781.) On the theory that *eclampsia* was due to excessive fibrin content of the blood, hirudin has been suggested as a therapeutic measure in this condition.

HOMATROPINÆ HYDROBROMIDUM.

U. S., Br.

HOMATROPINE HYDROBROMIDE Homatrop. Hydrobr. [Homatropine Bromide, Homatropine Hydrobromate]

(hō-măt-rō-pĭ′næ hȳ-drō-brō′mĭ-dŭm)

"The hydrobromide [$C_{16}H_{21}O_3N.HBr = 356.11$] of homatropine, an alkaloid obtained by the condensation of tropine and mandelic acid. Preserve it in well-closed containers, protected from light." *U. S.* "Homatropine Hydrobromide, $C_{16}H_{21}NO_3$,HBr, is the hydrobromide of an alkaloid prepared from tropine." *Br.*

Bromhydrate d'Homatropine, *Fr. Cod.;* Homatropinum hydrobromicum, *P. G.;* Homatropinhydrobromid, Bromwasserstoffsaures Homatropin, Bromwasserstoffsaures Oxytoluyltropein, *G.*

Preparation.—This alkaloidal salt was first admitted to the British Pharmacopœia in the additions of 1890. Homatropine, $C_{16}H_{21}NO_3$, is prepared by evaporating a mixture of tropine, $C_8H_{15}NO$ (obtained through the saponification of hyoscyamine), and *mandelic acid* (phenyl-glycollic), $C_6H_5.CH(OH)COOH$, with diluted hydrochloric acid; mandelic acid may be produced by acting on amygdalin with hydrochloric acid, or synthetically from benzaldehyde and hydrogen cyanide.

Properties.—Homatropine hydrobromide is officially described as follows: "A white, odorless, crystalline powder, or in rhombic prisms. *Great caution must be observed in tasting it, using only very dilute solutions.* Its solution when locally applied dilates the pupil of the eye. One Gm. of Homatropine Hydrobromide dissolves in 6 mils of water, 40 mils of alcohol, and in 420 mils of chloroform at 25° C. (77° F.); also in 12 mils of alcohol at 60° C. (140° F.); insoluble in ether. Its aqueous solution (1 in 20) is neutral to litmus. It melts at about 212° C. (413.6° F.) with partial decomposition. Shake 2 mils of chloroform with 1 mil of an aqueous solution of the salt (1 in 10) to which a few drops of chlorine water have been added; the chloroform assumes a brownish color. When added to solutions of Homatropine Hydrobromide, iodine T.S. produces a brown precipitate; silver nitrate T.S. in similar solutions produces a yellowish-white precipitate insoluble in nitric acid. No weighable ash remains on incinerating 0.1 Gm. of Homatropine Hydrobromide. Separate portions of 1 mil each of an aqueous solution of the salt (1 in 20) are not precipitated by tannic acid T.S.; or, after acidulation with hydrochloric acid, by platinic chloride T.S. (*foreign alkaloids*). Add a slight excess of ammonia water to 1 mil of an aqueous solution of the salt (1 in 100), shake it out with chloroform and evaporate the chloroformic solution to dryness on a water bath. The residue becomes yellow and finally brick-red in color when warmed with about 1.5 mils of a solution made by dissolving 1 Gm. of mercuric chloride in 50 mils of a mixture of 5 volumes of alcohol and 3 volumes of distilled water (distinction from *most other alkaloids except atropine and hyoscyamine*). Evaporate about 0.01 Gm. of Homatropine Hydrobromide, with 5 drops of nitric acid, to dryness in a porcelain dish on a water bath; the residue acquires no violet color on the addition of a few drops of alcoholic potassium hydroxide T.S. (*atropine, hyoscyamine, or hyoscine*)." *U. S.*

"White crystalline powder, or aggregations of minute crystals. Soluble in about 6 parts of *water,* and in about 18 parts of *alcohol* (90 per cent.), the solutions being neutral to *litmus.* Yields the *reactions* characteristic of bromides. An aqueous solution (1 in 100) applied to the eye powerfully dilates the pupil. 1 millilitre of this solution made alkaline with *solution of ammonia,* shaken with *chloroform,* the chloroformic solution being then separated and evaporated, yields a residue which turns first yellow and then brick-red when warmed with 1.5 millilitres of a solution (2 in 100) of *mercuric chloride* in *alcohol* (60 per cent.) When treated with *nitric acid* and *alcoholic solution of potassium hydroxide* as described under 'Atropina,' a reddish-yellow color is produced, not changing to violet (distinction from atropine)." *Br.*

Uses.—Homatropine is used in medicine solely as a mydriatic and cycloplegic. Its effects upon the eye are, like those of atropine, due to a paralyzing action upon the peripheral ending of

the oculo-motor nerve. It has the advantage over atropine in being relatively much less toxic to the general system and of being somewhat quicker in its action. It has in the past been stated that homatropine had no depressant effect upon the pneumogastric nerve, indeed that it slowed the pulse, but Zulick has shown (*J. P. Ex. T.*, 1915, vi, 473) that its effects upon cardiac inhibition are similar in kind to those of atropine, although it requires very large doses to affect the circulation. Occasionally unpleasant symptoms have followed the instillation of homatropine solutions into the eye, but we know of no fatal case of homatropine poisoning.

After the instillation of a 1 per cent. solution the pupil begins to dilate in from seven to twenty minutes and accommodation fails in forty to ninety minutes, while recovery is usually complete in three to four days. For simple dilatation of the pupil a 1 per cent. solution is sufficient, but when it is desired to paralyze accommodation completely a 2 per cent. solution may be employed.

Dose, internally, from one one-hundredth to one-fiftieth of a grain (0.0006–0.0013 Gm.).

Off. Prep.—Lamellæ Homatropinæ, *Br.*

HUMULUS. U. S.

HOPS Humul.

(hū'mŭ-lŭs)

"The carefully dried strobiles of *Humulus Lupulus* Linné (Fam. *Moraceæ*) bearing their glandular trichomes and without the presence or admixture of more than 2 per cent. of stems, leaves or other foreign matter. Preserve it in tightly-closed containers, protected from light." *U. S.*

Lupulus, *Br. Pharm.* 1898; Hop; Strobili Humuli, s. Lupuli; Houblon, *Fr. Cod.*; Hopfen, *G.*; Luppolo, *It.*; Lupulo (Fruto de), Hombrecillo, *Sp.*

Hops, under the title "Lupulus" were deleted from the British Pharm. (1914).

The hop plant is a twining, rough perennial having angular, rough, flexible stems, which twine around neighboring objects in a spiral direction from left to right, and climb to a great height. The leaves are opposite, and stand upon long footstalks. The smaller are sometimes cordate; the larger have three or five lobes; all are serrate, of a deep green color on the upper surface, and, together with the petioles, extremely rough, with minute prickles. At the base of the footstalks are two to four smooth, ovate, reflexed stipules. The flowers are numerous, axillary, and furnished with bracts. The staminate flowers are a yellowish-white, and arranged in panicles; the pistillate, which grow on a separate plant, are pale green, and disposed in solitary, peduncled aments, composed of membranous scales, ovate, acute, and tubular at the base. Each scale bears, near its base, on its inner surface, two flowers, consisting of a roundish compressed ovary, and two styles, with long filiform stigmas. The aments are converted into ovate membranous cones or strobiles, the scales of which contain, each, at its base, two small achenes, surrounded by a yellow, granular powder or the so-called *Lupulin*. Only the pistillate plants are cultivated by the hop growers in Europe, and it is interesting to note that the unfertilized pistillate plants produce strobiles richer in aroma and more plenteous in lupulin. The plants flower in August and the fruits are harvested during September. The hops grown in this country contain a great many achenes, showing that the staminate plants are also cultivated. The strobiles are collected when the scales change from a light golden to a somewhat deeper hue.

The hop plant is a native of North America and Europe. In parts of New England, New York, and Michigan it is extensively cultivated, and most of the hops consumed in the United States is supplied by those districts. England probably produces the largest quantity of hops, with Germany and Austria next in order. The part of the plant used is the fruit or strobiles. These, when fully ripe, are picked, dried by artificial heat, packed in bales, and sent into the market under the name of hops.

By separating the volatile oils and determining its acid and ester value, Rabak (*C. D.*, lxxxv, 376) is able to distinguish American grown from imported hops. He finds that the European hops always show a lower ester value in the volatile oil than do the American.

Hops consists of numerous thin, translucent, veined, leaf-like scales, which are of a pale greenish-yellow color, and contain near the base two small, round, black achenes. They are officially described as follows: "Strobile ovoid-cylindrical, about 3 cm. in length, consisting of a narrow, hairy, flexuous rachis and numerous, imbricated, yellowish-green to pale brown, obliquely-ovate, membranous scales, the base of each with numerous, yellowish-brown, glandular hairs, and frequently infolded on one side, enclosing a subglobular, light brown, very glandular achene; odor strong and characteristic, becoming disagreeable and valerian-like on aging; taste aromatic and bitter. Hops yield not more than 8 per cent. of ash." *U. S.*

Though brittle when quite dry, they are pulverized with great difficulty. Their odor is strong, peculiar and fragrant; their taste very bitter, aromatic, and slightly astringent. Their aroma, bitterness, and astringency are imparted to water by decoction, but the first mentioned property is dissipated by long boiling. The most active part of hops is a substance formed on the surface of the scales, and, in the dried fruit, existing in the state of very small granules. This substance was called *lupulin* by A. W. Ives of New York, by whom its properties were first investigated and made generally known, though it was previously noticed by Sir J. E. Smith of England, and Planche of France. The scales themselves, however, are not destitute of virtues, and contain, as shown by Payen and Chevallier, the same active principles as does lupulin, though in less proportion.

Hops are often subjected in Germany to the fumes of burning sulphur, because of the

supposition that they keep better when thus treated. Besides, by being partially bleached by the process, old hops, which have suffered from time, having become darker, generally spotted, and weaker, assume a brighter appearance, as if fresher, and generally command a better price in the market. To detect the consequent presence of sulphurous acid, the brewers put a silver spoon in a mixture of hops and water, under the impression that it will produce a black stain upon the silver. But this test will answer only when applied within a fortnight after the use of the sulphur. A more delicate method is that of Heidenreich, who puts twenty or thirty strobiles of the hops in a flask with zinc and hydrochloric acid, and passes the hydrogen evolved through solution of lead acetate. If sulphurous acid be present, hydrogen sulphide will be produced, which will occasion a dark precipitate with the solution. But even this plan often fails when the hops have been kept more than three or four weeks. A modification of this test has been proposed by R. Wagner. For the solution of lead acetate used in Heidenreich's method there is to be substituted a solution of sodium nitroprusside, so weak as to have a very light brown color, to which have been added a few drops of solution of potassium hydroxide. If the gas evolved contain the minutest proportion of sulphur, a violet color will be produced when the first bubble passes into the solution; and this will, by a continuance of the process become a magnificent purple. The least trace of sulphurous acid may thus be found, but a few months after the sulphuring of hops none at all can be detected.

Hops are said to be sometimes threshed in order to separate the lupulin, which is sold separately. Their efficiency is thus, no doubt, greatly impaired. Hops thus treated have the scales more or less broken; and any parcel presenting this appearance is to be suspected. Hops often contain a variable quantity of lupulin in consequence of the granules of this substance separating, especially on agitation, and seeking the lower portion of the mass, which thus becomes richer, while the upper is poorer. They should always be examined in reference to the lupulin they contain, and, if nearly or quite destitute of it, should be deemed of inferior value and not be used medicinally.

LUPULIN, N. F. IV (see also Part II).—Lupulin is obtained by rubbing or threshing and sifting the strobiles, of which it constitutes from one-sixth to one-tenth by weight. It is in the state of a yellowish powder, mixed with minute particles of the scales, from which it cannot be entirely freed when procured by a mechanical process. It has the peculiar flavor of hops, and appeared to Lebaillif and Raspail, when examined by the microscope, to consist of glandular hairs filled with a yellow matter. They originate in a cell formed among those of the epidermis, and, when fully developed, secreting a resinous matter. (*J. P. C.*, 3e sér., xxvi.) It is inflammable, and when moderately heated becomes somewhat adhesive. The odor of lupulinic grains resides in the essential oil. This is obtained to the extent of 0.9 per cent. by distilling hops with water. When distilled from the fresh strobiles the oil has a greenish color, but a reddish brown when old hops have been employed. It is devoid of rotatory power, neutral to litmus paper, and gives no remarkable coloration with concentrated sulphuric acid. According to Chapman (*J. Chem. S.*, 1895, 54, 780) the essential oil consists of two terpenes, one $C_{10}H_{16}$, and the other $C_{10}H_{18}$, boiling between 160° and 171° C. (320° and 339.8° F.) and a sesquiterpene called *humulene,* boiling at 263° to 266° C. (505.4°–510.8° F.). This latter makes up almost two-thirds of the oil. There is also a small amount of an oxygenated constituent, probably $C_{10}H_{18}O$. The bitter principle formerly called *lupulin* or *lupulite* was first isolated by Lermer, who called it the *bitter acid of hops* (*Hopfenbittersäure*). It crystallizes in large brittle rhombic prisms, and possesses the peculiar bitter taste of beer. Its composition is $C_{32}H_{50}O_7$. Lupulin consists chiefly of wax (*myricyl palmitate,* according to Lermer) and resins, one of which is crystalline and unites with bases.

Besides the constituents of the glands, hops contain, according to Etti, *lupulo-tannic acid* and *phlobaphene.* The former is a whitish, amorphous mass, soluble in alcohol, hot water, or acetic ether, but not in ether. By heating the *humulo-tannic acid* to 130° C. (266° F.), or by boiling its aqueous or alcoholic solution, it gives off water and is transformed into phlobaphene, a dark-red amorphous substance,

$$2C_{25}H_{24}O_{13} - H_2O = C_{50}H_{46}O_{25}$$

The latter substance, on boiling it with diluted mineral acids, becomes hydrolized, and furnishes glucose and *hop-red,* according to the reaction:

$$C_{50}H_{46}O_{25} + 2H_2O = C_{38}H_{26}O_{15} + 2C_6H_{12}O_6$$

From raw phlobaphene, ether removes the bitter principles of hops, a colorless crystallizable and a brown amorphous resin, besides chlorophyll and essential oil. (*Pharmacographia,* 2d ed.) The existence of a peculiar alkaloid in hops, suggested by Lermer in 1863, and confirmed by Griessmayer, has been denied. A. Chaston Chapman (*P. J.*, 1912, xcii, 878), found cultivated hops to contain from 1.7 to 4 per cent. of nitrogen which is a constituent of the following principles recognized by him in an investigation of the subject: aspartic acid, l-asparagine, choline, betaine, adenine, histidine, hypoxanthine, and arginine, besides an unidentified base, no trace of a morphine-like alkaloid could be detected, although this has been stated by some authorities to be present. Etti found arabic (pectic) acid, phosphates, nitrates, malates, citrates, and also sulphates, chiefly of potassium, to occur in hops. The amount of ash afforded by hops dried at 100° C. (212° F.) would appear to be on an average about 6 to 7 per cent. (U. S. P. IX not more than 8 per cent.) H. Bungener has isolated from hops a bitter crystalline substance, $C_{25}H_{36}O_4$, which is insoluble in water,

but soluble in alcohol and alkaline solutions. He believes it to be identical with Lermer's hop-bitter acid, to be feebly acid, and to possess the character of an aldehyde. (*P. J.*, 1884.)

Uses.—Hops are an aromatic bitter and hence may be useful in *atonic dyspepsia.* By many they are believed to have a sedative effect on the nervous system and are used in *hysteria, restlessness, isomnia,* and the like. Whether this latter action is due to anything more than an effect through the imagination is open to question.

An *infusion* prepared with half an ounce of hops and a pint of boiling water may be given in the dose of four fluidounces (120 mils). The tincture was a British official preparation of hops, but the alcohol probably acts more decidedly upon the system than the hops. The fluidextract of hops of the N. F. IV is superior because of the relatively smaller amount of alcohol. A pillow of hops has proved useful in allaying restlessness and producing sleep in nervous disorders. They should be moistened with water containing a trace of glycerin previously to being placed under the head of the patient, in order to prevent rustling. Fomentations with hops, and cataplasms made by mixing them with some emollient substance, are often beneficial in local pains and tumefactions.

The effects of hops may be obtained conveniently by the use of *lupulin,* which, although at one time much employed as an anaphrodisiac, has fallen into deserved desuetude.

Dose, thirty to ninety grains (2.0–5.8 Gm.).

HYDRARGYRI CHLORIDUM CORROSIVUM. U. S. (Br.)

CORROSIVE MERCURIC CHLORIDE Hydrarg. Chlor. Corr. [Bichloride of Mercury, Corrosive Sublimate, Mercuric Chloride Perchloride of Mercury]

(hȳ-drär′gy-rī ȼhlō′rī-dŭm cŏr-rō-sī′vŭm)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99.5 per cent. of $HgCl_2$ (271.52). Preserve it in well-closed containers." *U. S.* "Mercuric Chloride may be obtained as a sublimate by heating a mixture of mercuric sulphate, sodium chloride, and black oxide of manganese. It contains not less than 98.6 per cent. of pure mercuric chloride, $HgCl_2$." *Br.*

Hydrargyri Perchloridum, *Br.,* Perchloride of Mercury, Sublimatus Corrosivus, Chloruretum (Chloretum) Hydrargyricum, Hydrargyrum Corrosivum Sublimatum, Hydrargyri Bichloridum; Hydrargyrum Muriaticum Corrosivum, Sublimatus Corrosivus, Mercurius Sublimatus Corrosivus; Corrosive Chloride of Mercury, Sublimé corrosif, Chlorure mercurique, *Fr. Cod.;* Deutochlorure de Mercure, *Fr.;* Hydrargyrum Bichloratum, *P. G.;* Quecksilberchlorid, Aetzender Quecksilbersublimat, *G.;* Bicloruro di mercurio, *It.;* Cloruro mercurio, *Sp.*

The former official processes for this salt will be found in the U. S. D., 19th ed., p. 617.

The names given in the two Pharmacopœias to this important chloride do not exactly correspond. It is called *Hydrargyri Chloridum Corrosivum* in the U. S. Pharmacopœia, and *Hydrargyri Perchloridum* in the British. We prefer the former, as indicating, beyond any possibility of mistake, the article intended, as well as its corrosive property. Perchloride and subchloride are hardly sufficiently distinctive, when a mistake may be so serious as that of confounding corrosive sublimate and calomel. Indeed, death has at least in one recorded instance occurred in consequence of this confusion of nomenclature, and our official guides should take especial care to guard against such mistakes. The British Pharmacopœia (1898) uses for the English names mercuric chloride for corrosive sublimate and mercurous chloride for calomel, but these names are not used in prescription writing.

Preparation.—Corrosive sublimate may be made by heating sulphuric acid and the metal together, in a chamber so arranged as to carry off the sulphurous oxide, to form mercuric sulphate; the dry salt obtained is then mixed with sodium chloride, and the mixture sublimed. It is usually made on the large scale, by the direct combination of gaseous chlorine with mercury which is heated almost to the volatilizing point. This process was originally patented by A. T. Thomson, of London, England. It is also sometimes manufactured by dissolving mercuric oxide (red precipitate) in hydrochloric acid, evaporating the solution to dryness, dissolving the dry mass in water, and crystallizing. Here a double decomposition takes place, resulting in the formation of water and the chloride. This method may be used in emergencies for making small amounts.

Properties.—Corrosive mercuric chloride is officially described as in "heavy, colorless, rhombic crystals, or crystalline masses, or as a white powder, odorless, permanent in the air, and having a characteristic and persistent metallic taste. *Great caution should be used in tasting it.* One Gm. of Corrosive Mercuric Chloride dissolves in 13.5 mils of water, 3.8 mils of alcohol, about 12 mils of glycerin, and in 22 mils of ether, at 25° C. (77° F.); also in 2.1 mils of boiling water and 1.6 mils of boiling alcohol. The salt fuses to a colorless liquid at 265° C. (509° F.) and at about 300° C. (572° F.) it volatilizes in dense, white vapors, leaving not more than 0.1 per cent. of residue. An aqueous solution of Corrosive Mercuric Chloride (1 in 20) is acid to litmus, but becomes neutral upon the addition of sodium chloride. Separate portions of an aqueous solution of the salt (1 in 20) yield a white precipitate with ammonia water; a black precipitate with an excess of hydrogen sulphide; a red precipitate, soluble in an excess of the reagent, with potassium iodide T.S.; and a white precipitate, insoluble in nitric acid, with silver nitrate T.S. Not more than 0.5 per cent. of residue remains on dissolving finely powdered Corrosive Mercuric Chloride in ether or alcohol.

"**Assay.**—Dissolve about 0.5 Gm. of Corrosive Mercuric Chloride, previously dried to constant weight in a desiccator over sulphuric

acid and accurately weighed, in 300 mils of cold distilled water to which 1 mil of hydrochloric acid has been added. Pass hydrogen sulphide through the cold solution until saturated and the precipitate of mercuric sulphide readily subsides, leaving a clear supernatant liquid. Collect the precipitate on counterpoised filters, wash it well with cold distilled water and finally with three portions of about 10 mils each of alcohol. Then close the tip of the funnel with a cork stopper, add sufficient carbon tetrachloride to cover the precipitate, cover the funnel with a watch-glass, and allow it to stand for about half an hour. Then drain off the solvent and wash the precipitate with further portions of carbon tetrachloride until after evaporating about 1 mil of the filtrate no visible residue remains. Remove the adhering carbon tetrachloride by washing with several portions of 10 mils each of alcohol and, after drying in the air, transfer to an oven and dry to constant weight at about 110° C. (230° F.). The weight of mercuric sulphide obtained, when multiplied by 1.167, indicates its equivalent in $HgCl_2$, which corresponds in the dried salt to not less than 99.5 per cent. of $HgCl_2$.

"Each gramme of Corrosive Mercuric Chloride, previously dried to constant weight, corresponds to 0.8526 Gm. of mercuric sulphide.

"Corrosive Mercuric Chloride, previously dried to constant weight, may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"Heavy, colorless, crystalline masses, possessing a highly acrid, metallic taste. Soluble in 18 parts of *water,* and in 4 parts of *alcohol* (90 per cent.), or of *ether.* Yields the *reactions* characteristic of mercuric salts and of chlorides. When heated Mercuric Chloride sublimes without decomposition, leaving only a trace of fixed residue. Yields not less than 72.8 or more than 73.8 per cent. of metallic mercury, Hg, when tested by the following process:—Dissolve 0.5 gramme in 20 millilitres of *water* in a tared beaker-flask, add 10 millilitres of *hypophosphorous acid,* or sufficient to reduce the whole of the mercuric chloride present, and heat on a water-bath until the particles of mercury that separate collect at the bottom of the flask. Pour the contents of the flask on a tared filter-paper, wash both the flask and filter-paper successively with *water, alcohol* (90 per cent.), and *ether;* dry over *sulphuric acid,* and weigh the metallic precipitate." *Br.*

Ether is capable of removing corrosive sublimate, to a considerable extent, from its aqueous solution when agitated with it. According to Mialhe, ether will not dissolve it when accompanied by a considerable quantity of mercuric oxide and a chloride of an alkalifiable metal. Sulphuric, nitric, and hydrochloric acids dissolve it without alteration. When heated it melts, and readily sublimes in dense, white, acrid vapors, which condense on cool surfaces, in white, shining needles. Its aqueous solution renders green the syrup of violets, and is precipitated brick-red, becoming yellow, by the fixed alkalies and alkaline earths, and white by ammonia. (See *Hydrargyrum Ammoniatum.*) The former precipitate is mercuric oxide, which has the property of evolving oxygen and of being reduced to metallic globules when exposed to heat. This oxide is formed in the process for preparing *aqua phagedænica,* called also *yellow wash.* (See *Lotio Hydrargyri Flava.*) Corrosive sublimate forms, with ammonium chloride and sodium chloride, compounds which are more soluble than the uncombined mercurial salt. The combination of corrosive sublimate with ammonium chloride was formerly called *sal alembroth,* or *salt of wisdom.* According to F. Hinterberger, corrosive sublimate is capable of combining with quinine and cinchonine. (*Chem. Gaz.,* ix, 211.) By dissolving one part of corrosive sublimate and a hundred parts of sodium chloride in distilled water and evaporating to dryness, a soluble preparation is obtained which does not coagulate albumen. (*A. J. P.,* xliv, 11.) J. F. Brown (*C. D.,* 1896, 425) recommended for dispensing purposes a solution of mercuric chloride of such strength that ten minims contain one grain, made by dissolving ninety-six grains of corrosive sublimate in one and a half ounces avoirdupois of glycerin and six fluidrachms of distilled water by the aid of heat, then cooling the solution and adding distilled water until the solution measures two fluidounces.

Tests.—Pure corrosive chloride of mercury sublimes, when heated, without residue, and its powder is entirely and readily soluble in ether. Consequently, if a portion of any sample should not wholly dissolve in ether, or if it should not evaporate entirely, the presence of some impurity is proved. The U. S. P. IX limiting test is not more than 0.5 per cent. of residue on treatment with ether or alcohol. If calomel be present, and it frequently is, it will not be wholly soluble in water. Arsenic is reported to be a frequent impurity in corrosive sublimate. (See paper by J. Granville Smith, *A. J. P.,* 1877, p. 397.) Corrosive sublimate is incompatible with many of the metals, the alkalies and their carbonates, soap, lime water, tartar emetic, silver nitrate, the lead acetates, the potassium and sodium sulphides, the soluble iodides, and all the sulphydrates. It is decomposed by many vegetable and some animal substances. According to A. T. Thomson, it produces precipitates in infusions or decoctions of chamomile, horseradish, calumba, cinchona, gambir, rhubarb, senna, simaruba, and oak bark. Mialhe and Lepage have shown that corrosive sublimate is slowly converted into calomel by syrup of sarsaparilla and syrup of honey, but is not changed by contact with pure syrup. Samuel Kennedy (*Ph. Rec.,* 1888, p. 201) proved conclusively that when corrosive sublimate was dissolved in compound syrup of sarsaparilla, as frequently prescribed, precipitation invariably occurred. He found that if sodium chloride in quantity equalling that of the mercurial used

were added, precipitation was greatly retarded.

Uses.—Corrosive sublimate is a powerful mercurial and may be used for the various purposes for which the other preparations of this metal are employed. (See page 566.) When administered in large doses it is prone to irritate the stomach and intestines and, therefore, such large quantities of mercury cannot be introduced into the system with this salt as with calomel. It is probably the best of all the preparations of mercury for hypodermic use in *syphilis*. From ten to twenty minims of an 0.5 per cent. solution in distilled water may be thrown deeply into the muscles, preferably of the back. The pain of the injection may be obviated by the previous injection of cocaine. Most careful asepsis is necessary to avoid abscess formation.

It has been employed, especially by intravenous injection with asserted benefit in *septicemia*, especially following child-birth. Stowe (*Chicago Medical Recorder*, 1911, xxxiii, p. 461) injects one-fifth of a grain at a dose.

Externally employed, corrosive sublimate is stimulant, escharotic, and germicidal. The powdered chloride has been used as an escharotic, but is, in general, inferior to silver nitrate or potassium hydroxide. In *onychia maligna*, however, it is employed with great advantage, mixed with an equal weight of zinc sulphate, and sprinkled thickly upon the surface of the ulcer, which is then to be covered with a pledget of lint saturated with tincture of myrrh. The whole diseased surface is thus removed, and the ulcer heals. This practice originated, we believe, with Perkins, of Philadelphia, and was highly recommended by Physick. Geo. B. Wood often employed it with success. A solution of corrosive sublimate in collodion (four parts to thirty) has been used as a caustic, for the destruction of *nævi materni*, and for other purposes. It can be very accurately applied, but its use requires care, as fatal poisoning has followed a single application of the alcoholic solution of corrosive sublimate to a moderate surface of *ringworm*. (*L. L.*, 1871, ii, 413.) It is applied by means of a camel's-hair pencil.

Corrosive sublimate is one of the most powerful of known chemical germicides. Solutions containing one part in twenty thousand are sufficient to destroy the vitality of most non-sporulating bacteria while one in one thousand will kill the most resistant sporulating organisms. According to Koch, one part in three hundred thousand absolutely prevents the multiplication of the *Bacillus anthracis*, while Behring (*D. M. W.*, 1887) finds that as little as one part in a million has a distinctly inhibiting effect. The practical utility of mercuric chloride as a disinfectant is, however, greatly limited by its chemical instability. It has a strong affinity for albumen and, although the precipitate formed is redissolved in an excess of albumen, the disinfectant power of mercury is very much reduced. Moreover, it attacks most metals which are used in surgery and is therefore unsuitable for disinfecting instruments. Nevertheless, because of its convenience as well as its powerful action it is perhaps the most commonly employed germicide for surgical purposes.

The solution of one in one thousand may be used for washing the hands, disinfecting furniture, etc., and is even employed in the disinfecting of *wounds;* usually, however, a much weaker solution than that just mentioned is employed by the surgeon. It is rarely if ever justifiable to use upon a mucous surface or a wound a solution stronger than one in two thousand, and if the solution is to be used freely and continuously, as in washing out the vagina, etc., one in ten thousand is as strong as should be employed; indeed, the employment of a vaginal wash of this strength has been followed by violent poisoning. (See H. C. Wood, Jr., *Am. Med.*, Dec., 1902.) In a number of cases a solution of one part in fifteen hundred used locally by the surgeon has produced death, preceded by constitutional symptoms.

It is essential that the tablets be colored or in some way marked so that the attention may be drawn to their nature, and accidental poisoning prevented. Mercuric chloride tablets are now officially recognized. (See *Toxitabellæ Hydrargyri Chloridi Corrosivi.*)

Poisoning.—Because of the ease with which it is obtained corrosive sublimate is one of the most commonly used poisons for suicidal purposes, and the wide spread employment of tablets of it as antiseptics has led to a number of accidental cases. The symptoms of poisoning by bichloride of mercury generally come on promptly with a metallic taste, burning pain in the gullet and epigastrium, followed by vomiting and purging. The vomitus is first mucous or bilious, but later becomes bloody, the stools also usually contain blood. In many cases there is a profound collapse, as shown by rapid feeble pulse, cold clammy skin, and muscular weakness, even comparatively early in the poisoning. The urine becomes scanty or maybe entirely suppressed, albuminous, and sometimes hemorrhagic. If the patient survives for a few days salivation develops and ulcers appear around the mouth and throat. Death may occur within a few hours of the ingestion of the poison, but may be postponed for nearly a fortnight. On postmortem examination the whole alimentary canal is found the seat of a corrosive inflammation, there is violent nephritis and sometimes protoplasmic degenerations in the internal organs. It is not necessary for the poison to be swallowed in order to produce serious or even fatal results. H. C. Wood, Jr. (*American Medicine*, 1902, iv, p. 1006), has found references to more than 150 cases of poisoning from its use as intra-uterine douches of which a large number ended fatally, and Craig (*J. A. M. A.*, 1906, xlvii, p. 1484) has reported death from the application of an alcoholic solution to the back and arm.

In the treatment of acute poisoning by mercuric chloride, the stomach should be at once evacuated, preferably by means of the stomach

tube or by the hypodermic injection of apomorphine. The most available antidote is some form of albumin, as milk, egg, or hashed meat; according to Taddei, wheat flour may be used, gluten having the same antidotal properties as albumen. As the albuminate of mercury is soluble in an excess of albumen and probably under other conditions, it is important to continue the evacuation of the stomach even after the administration of the antidote. Fantus (*Jour. of Lab. and Clin. Med.*, 1916, i, 879) from an elaborate experimental study reaches the conclusion that the antidotal value of albumin has been greatly overestimated. He recommends a mixture of sodium hypophosphite with sodium acetate. After the evacuation of the stomach and the efforts at neutralizing the local irritant effects of the drug, elimination should be encouraged by the free use of water both by the mouth and hypodermic injection of salt solution. Counter irritation over the kidneys and demulcent drinks are indicated and such other symptoms as arise may be met with appropriate remedies.

Tests for Corrosive Sublimate.—On account of the extreme virulence of this chloride as a poison, the reagents by which it may be detected form a subject of study of the utmost importance, as connected with medico-legal investigations.

If the mixture suspected of containing corrosive sublimate be wholly inorganic the following tests may be used for its detection: A preliminary test for mercury may be made with copper foil and strong hydrochloric acid. (Reinsch's test.) If the foil be darkened or changed it may be dried, placed in a tube of hard glass and heated when mercury will distil and separate in the cooler portions of the tube where it may be recognized by an examination under the microscope which will reveal the characteristic globules of the element. Tests in an aqueous solution of the substance may also be applied with hydrogen sulphide solution, which precipitates black mercuric sulphide; with potassium iodide solution, which cautiously added in just the proper amount precipitates red mercuric iodide; with an alkaline carbonate or hydroxide, which will precipitate the yellow mercuric oxide; and with stannous chloride solution which will reduce mercuric salts to mercurous and will thus give a white precipitate of calomel. The chlorine may be recognized by the customary silver nitrate test.

If any organic matter be present most or all of the foregoing tests will fail and as if ignition be resorted to, the mercury compounds will probably be volatilized, the destruction of the organic matter must be accomplished in the wet way by heating the substance with strong hydrochloric acid, and then cautiously adding powdered potassium chlorate in small portions, continuing the heating until the organic matter is completely destroyed and the dark color which the mixture originally assumed upon heating with the acid, has changed to a clear golden yellow. This solution may then be carefully heated to drive off the free chlorine and the tests as previously described may be applied.

Dose, of corrosive sublimate, from one-fortieth to one-eighth of a grain (0.0015–0.008 Gm.), preferably given after meals, in solution.

HYDRARGYRI CHLORIDUM MITE.
U. S. (Br.)

MILD MERCUROUS CHLORIDE Hydrarg. Chlor. Mit. [Calomel, Mercurous Chloride, Protochloride of Mercury, Subchloride of Mercury]

(hȳ-drär′gy-rī ȼhlō′rī-dŭm mī′tē)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99.6 per cent. of HgCl (236.06). Preserve it in well-closed containers, protected from light." *U. S.* "Mercurous Chloride, HgCl, is obtained as a sublimate by heating a mixture of mercurous sulphate and sodium chloride." *Br.*

Hydrargyri Subchloridum, *Br.*, Calomelas; Hydrargyri Chloridum, Hydrargyrum Chloratum (Muriaticum), Mercurius Dulcis, Chloruretum Hydrargyrosum; Mild Chloride of Mercury, Submuriate of Mercury; Chlorure Mercureux, *Fr. Cod.;* Protochlorure ou Sous-muriate de Mercure, Calomel, *Fr.;* Hydrargyrum Chloratum, *P. G.;* Quecksilberchlorür, *G.;* Protocloruro di mercurio, *It.;* Cloruro mercurioso sublimado, *Sp.*

Very properly, processes for this compound have been omitted from the Pharmacopœias, as it cannot be made by the pharmacist conveniently. For processes of the U. S. P., 1870, and of the Br. Pharm., 1885, with remarks, see *U. S. Dispensatory*, 19th edition, p. 623.

The original method of making calomel was practised at Apothecaries' Hall, London, by taking advantage of the following reaction:

$$HgSO_4 + 2NaCl + Hg = Na_2SO_4 + 2HgCl$$

To bring the calomel into a state of minute division the method of Joseph Jewell, of London, improved by Ossian Henry, is sometimes employed. It consists in causing the calomel in vapor to come in contact with steam in a large receiver, whereby it is condensed into an impalpable powder, and perfectly washed from corrosive sublimate in the same operation. Calomel made by this process, sometimes called Jewell's or Howard's *hydrosublimate of mercury*, is free from all suspicion of containing corrosive sublimate, and is much finer than when obtained by levigation and elutriation. This kind of calomel is included in the French Codex under a distinct name. (*Mercure* (*Protochlorure de*) *par volatilization.*) Soubeiran, of Paris, perfected a process for obtaining calomel as an impalpable powder, by substituting the agency of cold air for that of steam for the purpose of condensing it. A description of his apparatus may be found in the *J. P. C.* (3e sér., ii.), and of the English

apparatus, as described by F. C. Calvert, in the same journal (3e sér., iii). Both these papers were copied into the *A. J. P.* (xv).

Calomel may also be prepared in the dry way by taking four parts of corrosive sublimate and rubbing it up in a mortar with three parts of mercury, after moistening the mass with alcohol. The powder is then dried and sublimed in glass flasks. The powder should be dried quickly before sublimation, so as to drive off any trace of uncombined mercury. A comparative examination of English and American calomel was undertaken separately in 1885 by Bedford and Patch. (See *Proc. A. Ph. A.*, 1885.) While there was no reason for preferring English calomel, none of the samples exhibited more than traces of mercuric chloride. Calomel is also made in the wet way by Wöhler's method by precipitating a solution of corrosive sublimate by a stream of sulphurous acid, taking advantage of a reaction first observed by Vogel. Calomel obtained in the humid way, called *precipitated calomel,* was formerly official with the Dublin College, and was adopted in the French Codex. This form of calomel is a crystalline powder, which is unfit for use until after elaborate levigation and elutriation.

Properties.—When in mass, its form and appearance depend on the shape and temperature of the subliming vessel. In this state it is generally in the form of a white, fibrous, crystalline cake, the interior of which is often studded with shining transparent crystals, having the shape of quadrangular prisms, and a texture somewhat horny and elastic. When the mass is scratched it yields a yellow streak, which is very characteristic. Its sp. gr. is 7.2. Patch found (*Proc. A. Ph. A.*, 1885, p. 477) the sp. gr. of calomel to vary from 6.94 to 7.93, the standard being water at 3.9° C. (39° F.). Powder is the official form of this chloride, in which state it is always kept by pharmacists. The powder has a light buff or ivory color, if obtained by the levigation of sublimed masses; but if condensed at once in the form of an impalpable powder, it is perfectly white. To protect it from the action of the light, it should be kept in a dark place, or in bottles painted black or covered with black paper. By the action of the fixed alkalies or alkaline earths it immediately becomes black, in consequence of the formation of mercurous oxide, reducible by heat to the metallic state. The preparation employed under the name of *lotio nigra,* or *black wash,* as a local application to syphilitic *ulcers,* etc., is made by adding a *drachm* of calomel to a *pint* of lime water. (See *Lotio Nigra.*)

It is officially described as "a white, impalpable powder, becoming yellowish-white on being triturated with strong pressure, and showing only small, isolated crystals when viewed under a lens having a magnifying power of one hundred diameters. It is odorless and tasteless, and permanent in the air. Mild Mercurous Chloride is insoluble in water, alcohol, ether or cold dilute acid. When strongly heated, Mild Mercurous Chloride is volatilized without fusion or the evolution of brown vapors, leaving not more than 0.1 per cent. of residue. The salt is blackened by contact with calcium hydroxide T.S., with solutions of alkali hydroxides or with ammonia water. When heated with an equal weight of dried sodium carbonate (free from chloride) in a dry glass tube, Mild Mercurous Chloride yields a sublimate of metallic mercury. Dissolve the residue in nitric acid and filter; silver nitrate T.S. produces in the filtrate a white, curdy precipitate insoluble in nitric acid. Shake 2 Gm. of the salt with 20 mils of ether, filter, evaporate the filtrate, and add 10 mils of distilled water; not more than a slight opalescence results upon the addition of silver nitrate T.S. to 5 mils of the solution (*mercuric chloride*). Heat 1 Gm. of the salt with potassium hydroxide T.S.; no ammonia is evolved (*ammoniated mercury*).

"**Assay.**—Mix, in a tared flask, about 1 Gm. of Mild Mercurous Chloride, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, with 10 mils of distilled water, add 50 mils of tenth-normal iodine V.S. and 5 Gm. of potassium iodide, dissolved in 10 mils of distilled water, stopper the flask, allow the mixture to stand, with occasional agitation, until complete solution has taken place and estimate the excess of iodine by titration with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows, in the dried salt, not less than 99.6 per cent. of HgCl.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.023606 Gm. of HgCl. Each gramme of Mild Mercurous Chloride, previously dried to constant weight, corresponds to not less than 42.2 mils of tenth-normal iodine V.S.

"Mild Mercurous Chloride, previously dried to constant weight, may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"A heavy dull white powder, sometimes rendered yellowish by prolonged trituration; nearly tasteless. Insoluble in *water,* in *alcohol* (90 per cent.), and in *ether;* soluble in a boiling mixture of *nitric acid* and *hydrochloric acid,* the solution, when diluted with *water,* yielding the *reactions* characteristic of mercuric salts. Volatilises when sufficiently heated, leaving not more than a trace of fixed residue. Warmed with *solution of sodium hydroxide* it becomes black, but does not evolve ammonia (absence of mercuric-ammonium chloride). When 1 gramme is well shaken with 10 millilitres of *water* and filtered, the filtrate is not darkened by *hydrogen sulphide* (absence of mercuric chloride)." *Br.*

An easy method of detecting corrosive sublimate, proposed by Bonnewyn, is to put some of the suspected powder upon a well polished surface of iron, and then moisten it with a drop of alcohol or ether. If the calomel be pure the surface will remain quite unaffected.

while it will be blackened by corrosive sublimate if present in the proportion of only 1 to 50,000. (*J. P. C.*, 1865, 4e sér., ii, 79.) The presence of any soluble chloride whatever in the calomel would be detected by the production of a precipitate by silver nitrate with the washing. Soluble salts of mercury may be detected by rubbing the suspected calomel with ether on a bright surface of copper, when the metal will become amalgamated and exhibit a white stain. When this test shows impurity, the soluble salt present is probably corrosive sublimate. Calomel containing corrosive sublimate acts violently on the bowels, and, when the impurity has been present in considerable amount, has been known to cause death. Besides being incompatible with the alkalies and alkaline earths, calomel is also decomposed by the alkaline carbonates, soaps, sulphydrates, and, according to some authorities, by iron, lead, and copper. By boiling with the alkaline formates it is decomposed, and metallic mercury liberated. (H. Rose, *Annal. der Physik und Chem.*, cvi, 500.)

Calomel should not be given at the same time with nitrohydrochloric acid, for fear of generating corrosive sublimate; death is reported to have followed such a combination. According to the experiments of Deschamps, calomel is decomposed by bitter almonds and by hydrocyanic acid. In the former case corrosive sublimate, mercuric cyanide, and ammonium chloride are formed; in the latter, corrosive sublimate and mercuric cyanide only; hence this writer considers it very dangerous to associate calomel with bitter almonds or hydrocyanic acid in prescription. This conclusion has been confirmed by Mialhe and Prenleloup, and more recently it has been shown by E. Riegel that cherry-laurel water has the power of converting calomel into corrosive sublimate. According to Mialhe calomel is in part converted into corrosive sublimate and metallic mercury by ammonium chloride and by sodium and potassium chlorides, even at the temperature of the body; hence he believes that the conversion may take place in the primæ viæ. Diekman (*Pharm. Era*, xxii, 7) experimented upon this subject and showed that the amount of mercuric chloride thus formed is not over 0.6 per cent. of the calomel taken, and consequently must be considered as negligible.

Uses.—As an alterative calomel may be used for the general properties of the mercurials. (See page 566.) It is relatively non-irritant to mucous membranes and may be given in large doses so that it is possible to bring the system under the general influence of the mercury very rapidly.

Aside from its alterative action, mercurous chloride is used as a cathartic, diuretic, and antiseptic. As a laxative it is slow but thorough in its action, affecting both upper and lower bowels. While the former belief that it was a stimulant to hepatic secretion has been shown to be incorrect, it in some way increases the bile in the intestinal tract, perhaps through an action on the bile passages or perhaps through its antiseptic effect preventing the decomposition of the natural bile. It is therefore preferred in cases where there is an absence of this secretion as shown by light colored stools, and in *biliousness*. It is also a valuable agent to cleanse the intestines in *enteritis* both because of the thoroughness of its effect and of its antiseptic action. When used as a purgative better effects may be obtained with less discomfort by giving it in divided doses, thus a quarter of a grain may be given every half hour until three or four grains have been taken. It is usually advisable to follow it the next day with a saline for the reason that if it should fail to operate sufficient calomel may be absorbed to cause salivation.

The mode of action of calomel as a diuretic is not yet positively determined, but there is abundant evidence that it is one of the most powerful stimulants to the kidney which we possess. According to Fleckseder (*W. K. W.*, 1911, p. 1421), it is especially useful in the severe dropsies of heart disease after the failure of other drugs. An old combination with digitalis and squill, frequently but incorrectly spoken of as *Niemeyer's pill*, is widely employed for this purpose. To obtain its diuretic effect it is usually necessary to give it in large doses. Ordinarily from a quarter to half a grain may be given every two hours until beginning ptyalism, but in emergencies where an immediate effect is desired it may be well to give five grains (0.32 Gm.) at once, repeating every two hours until fifteen grains (0.9 Gm.) have been taken. Purgative action may be guarded against by the simultaneous exhibition of opium.

Although calomel has long been used both externally and internally for its disinfectant properties, the studies of Schamberg and Kolmer (*J. A. M. A.*, 1914, lxii, p. 1950) indicate that its germicidal power has been underestimated. According to these investigators, weight for weight it is equal to the corrosive sublimate. Externally it is used for a dusting powder in various infections of the eye, and in *venereal ulcers*. Internally it is used for its antiseptic action in various types of *enteritis* or *dysentery*. Some commercial cosmetic preparations contain calomel in suspension, and it has always been found difficult or impossible to duplicate these smooth suspensions with commercial calomel, which first forms a curd and then rapidly settles out. F. W. Nitardy (*J. A. Ph. A.*, 1914, p. 965) found it possible to communicate the desired suspending qualities to ordinary calomel by first adding 5 per cent. by volume of mucilage of acacia, which produces a fine suspension, then allowing the calomel to settle out, decanting and discarding the supernatant liquid and replacing it with distilled water. By repeating this operation several times the acacia is all removed but the calomel retains its marked suspending quality.

The *dose* of calomel as an alterative is from one-sixth to one-third of a grain (0.01–0.02 Gm.); as a cathartic, from two to five grains (0.12–0.3 Gm.).

HYDRARGYRI IODIDUM FLAVUM. U. S.

YELLOW MERCUROUS IODIDE Hydrarg. Iod. Flav. [Mercurous Iodide, Protoiodide of Mercury, Yellow Iodide of Mercury]

(hȳ-drär′gy-rī ī-ōd′ī-dŭm flā′vŭm)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99 per cent. of HgI (327.52). Preserve it in well-closed containers, protected from light." *U. S.*

Hydrargyri Iodidum Viride, U. S. P. 1880; Green Iodide of Mercury, Hydrargyri Iodidum, U. S. P. 1850; Iodide of Mercury, Hydrargyrum Iodatum Flavum, Hydrargyri Protoioduretum, Ioduretum Hydrargyrosum; Protiodure de Mercure, Iodure mercureux, *Fr. Cod.;* Gelbes Jodquecksilber, *G.;* Protojoduro di mercurio, *It.;* Yoduro mercurioso, *Sp.*

The U. S. P. IX omitted a process for making yellow mercurous iodide. The U. S. P. VIII process was as follows:

"Mercury, *fifty grammes* [or 1 ounce av., 334 grains]; Nitric Acid, Potassium Iodide, Distilled Water, each, *a sufficient quantity.* Mix *twenty mils* [or 325 minims], each, of Nitric Acid and Distilled Water, and, when the liquid is cold, pour it upon the Mercury contained in a glass beaker. Set the mixture aside in a dark place, and keep it at a temperature between 25° and 30° C. (77° and 86° F.), with occasional agitation, until the reaction ceases and a little mercury still remains undissolved. Separate the crystals of mercurous nitrate, which will have formed, from the mother-liquid, allow them to drain in a glass funnel, and dry them on bibulous paper, in a dark place. When the salt is dry dissolve *forty grammes* [or 1 ounce av., 180 grains] of it in *six hundred and fifty mils* [or 21 fluidounces, 470 minims] of Distilled Water to which *six mils* [or 97 minims] of Nitric Acid have previously been added. Having prepared a solution of *sixteen grammes* [or 247 grains] of Potassium Iodide in *thirty-two mils* [or 1 fluidounce, 39 minims] of Distilled Water, slowly pour the solution of Potassium Iodide into the solution of Mercurous Nitrate, with constant stirring, which should be continued for fifteen minutes, allow the precipitate to subside, decant the supernatant liquid, and wash the precipitate by decantation with ten successive portions of *five hundred mils* [or 16 fluidounces, 435 minims] each of Distilled Water. Finally, transfer the precipitate to a filter, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 40° C. (104° F.), and keep it in dark amber-colored vials, with the least possible exposure to light. Instead of weighing off *forty grammes* [or 1 ounce av., 180 grains] of the Mercurous Nitrate as above directed, the whole of the crystallized salt may be taken and the amount of Potassium Iodide, etc., adjusted to the proportions given above."

The Br. Pharm. dropped this salt at its 1885 revision, and has not restored it.

The process of the U. S. P. VIII differed from that official in 1880 for green iodide of mercury. (See *U. S. Dispensatory,* 19th ed., p. 627.) It is essentially the process recommended by Edward Soetje (*Proc. A. Ph. A.,* 1888, p. 167), the product is the result of double decomposition between mercurous nitrate and potassium iodide, in solution, *yellow* mercurous iodide and potassium nitrate being formed. This method of making mercurous iodide has long been known, but the disadvantage heretofore has been that some mercuric iodide was formed, which contaminated the product; the thorough washing by ten successive portions of distilled water should remove all traces of this impurity. Several other methods of making mercurous iodide have been proposed. (See *U. S. D.,* 19th ed., p. 627.)

George A. Haffa precipitated a solution of mercurous nitrate with potassium iodide, and obtained mercurous iodide of a yellow or green color according to the density of the solution. The solution of mercurous nitrate is prepared by acting upon 15,000 gr. of mercury with a cold mixture of nitric acid (6000 gr.) and water (4000 gr.), placing the vessel in cold water, and stirring the contents constantly until the reaction has entirely ceased; the white crystalline mass, without being separated from the excess of metallic mercury, is then dissolved in water acidulated with nitric acid (1 oz. to the gallon) until the solution measures four pints. For preparing *green mercurous iodide,* six ounces of a solution of mercurous nitrate are mixed with six pints of water, and there is added in a continuous stream, and with constant stirring, a solution of potassium iodide (3 oz. in 54 oz. of water); the precipitate is washed with water, and dried without the aid of heat. *Yellow mercurous iodide* is prepared in the same manner, except that two ounces of solution of mercurous nitrate diluted with water (8 pints) are used with a solution of potassium iodide (1 oz. in 4 pints of water). This salt darkens much more quickly when exposed to the light than that made by the U. S. P. 1880 process. (*A. J. P.,* 1886.) Stomen practically confirms these results. (*Ber. d. Chem. Ges.,* 1887; see also *Ph. Era,* 1888.) From experiments by H. C. Wood, it appears that the green iodide is a mixture of yellow iodide and metallic mercury. By continuing the trituration, the powders become more and more yellow, and at length have only a tinge of green. He infers that pure mercurous iodide is yellow, and that the green color is owing to an admixture of the blue of the mercury with the yellow of the mercurous iodide. (*P. J.,* 1868.) Flückiger (*Pharmaceutische Chemie,* 2d ed., 1888) agrees with this view, and says that by slow sublimation, at a very gentle heat,

the true mercurous iodide can be obtained in small transparent yellow crystals of the quadratic system which are related to the forms of calomel. (See *J. P. C.*, 1894, 67.) Francois's process is essentially the result of the reducing action of aldehyde on iodomercurammonium iodide. (*J. P. C.*, 1894, 67.)

Properties.—It is officially described as "a bright yellow, amorphous powder, odorless and tasteless. By exposure to light it becomes greenish in proportion as it undergoes decomposition into metallic mercury and mercuric iodide. Yellow Mercurous Iodide is almost insoluble in water and wholly insoluble in alcohol or ether. When slowly and moderately heated, it assumes at first an orange and then a red color, becoming yellow again on cooling. When quickly and strongly heated, it is at first partially decomposed into mercury and mercuric iodide, and finally is volatilized, leaving not more than 0.2 per cent. of residue. When heated with an equal weight of dried sodium carbonate, in a dry glass tube, Yellow Mercurous Iodide yields a sublimate of metallic mercury. When Yellow Mercurous Iodide is heated with sulphuric acid and a little manganese dioxide, the vapor of iodine is evolved. When 0.5 Gm. of the salt is thoroughly shaken with 10 mils of alcohol and the mixture filtered, 5 mils of the perfectly clear filtrate is not affected by an equal volume of hydrogen sulphide T.S. (*mercuric iodide*).

"**Assay.**—Transfer to a flask about 1 Gm. of Yellow Mercurous Iodide, previously dried to constant weight in a desiccator over sulphuric acid and accurately weighed, add 50 mils of tenth-normal iodine V.S. and 5 Gm. of potassium iodide, dissolved in 10 mils of distilled water, stopper the flask, and allow the mixture to stand in the tightly-stoppered flask, with occasional agitation, until complete solution has taken place. Then titrate with tenth-normal sodium thiosulphate V.S., using starch T.S. as indicator. It shows, in the dried salt, not less than 99 per cent. of HgI.

"Each mil of tenth-normal iodine V.S. used corresponds to 0.032752 Gm. of HgI. Each gramme of Yellow Mercurous Iodide, previously dried to constant weight, corresponds to not less than 30.2 mils of tenth-normal iodine V.S.

"Yellow Mercurous Iodide, previously dried to constant weight, may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

Its sp. gr. is 7.75. If quickly and cautiously heated, it sublimes in red crystals, which afterwards become yellow. "Gradually heated in a test-tube, it yields a yellow sublimate, which, upon friction, or after cooling, becomes red, while globules of metallic mercury are left in the bottom of the tube." *Br.* 1867.

Uses.—Mercurous iodide is used in advanced *syphilis*. The dose is one-fifth of a grain (0.012 Gm.), gradually increased to two grains (0.13 Gm.). It should never be given at the same time with potassium iodide, which converts it into mercuric iodide and metallic mercury.

Dose, one-fifth of a grain (0.012 Gm.).

HYDRARGYRI IODIDUM RUBRUM
U. S., Br.

RED MERCURIC IODIDE Hydrarg. Iod. Rub. [Biniodide of Mercury, Mercuric Iodide, Red Iodide of Mercury]

(hȳ-drär'gy-rī ī-ōd'ī-dŭm rŭ'brŭm)

"It contains, when dried to constant weight in a desiccator over sulphuric acid, not less than 99 per cent. of HgI_2 (454.44). Preserve it in well-closed containers, protected from light." *U. S.* "Red Mercuric Iodide, HgI_2, is obtained by the interaction of aqueous solutions of mercuric chloride and potassium iodide." *Br.*

Mercurius Iodatus Ruber, Deutoioduretum Hydrargyri, Hydrargyrum Iodatum Rubrum, Ioduretum Hydrargyricum; Deutoiodide of Mercury; Iodure mercurique, *Fr. Cod.*; Deuto-iodure (Bi-iodure) de Mercure, *Fr.*; Hydrargyrum Bijodatum, *P. G.*; Quecksilberjodid, Rothes Jodquecksilber, *G.*; Bijoduro di mercurio, *It.*; Yoduro mercurico, *Sp.*

No process for preparing this salt is given in the U. S. P. IX, nor British Pharm. (1914). The U. S. P. VIII process is appended.

"Corrosive Mercuric Chloride, *forty grammes* [or 1 ounce av., 180 grains]; Potassium Iodide, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *a sufficient quantity*. Dissolve the Corrosive Mercuric Chloride and the Potassium Iodide, each, in *eight hundred mils* [or 27 fluidounces, 24 minims] of Distilled Water, and filter the solutions separately. Pour both solutions, simultaneously and in a thin stream, with constant and very active stirring, into *two thousand mils* [or 67 fluidounces, 5 fluidrachms] of Distilled Water. When the precipitate has subsided, decant the supernatant liquid, collect the precipitate on a filter, and wash it with cold Distilled Water, until the washings give not more than a slight opalescence with silver nitrate test solution. Finally, dry it in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.), and keep it in well-stoppered bottles, protected from light."

In the above process for forming mercuric iodide a double decomposition takes place between corrosive sublimate and potassium iodide. resulting in the formation of potassium chloride which remains in solution, and mercuric iodide which precipitates. The precipitate is soluble in the reacting salts, and hence a loss of part of it is incurred by an excess of either. It is best, however, to have a slight excess of the potassium iodide, which is furnished by the proportion taken in the formula, as then decomposition of the whole of the corrosive sublimate is insured, and any contamination of the mercuric iodide by it prevented; loss by solution in the supernatant liquid is largely obviated by the improvement which was first introduced in the U. S. P. 1890, whereby separate solutions are poured simultaneously into a large volume of water.

For other methods of preparing this salt see *U. S. D.*, 19th ed., p. 629.

Properties.—As obtained by the old Edinburgh process, it is in splendid crimson acicular

crystals. Köhler has found, however, that it crystallizes better from boiling hydrochloric acid. (*Ber. d. Chem. Ges.*, 1879, p. 608.) It also crystallizes well from hot saturated solutions in acetone, glacial acetic acid, absolute alcohol, amyl alcohol, and nitric acid of 1.2 sp. gr., see also *Chem. News*, 1900, 24. When heated the mass becomes yellow at about 150° C. (302° F.), melting at 254° C. (489.2° F.) to a dark yellow liquid, and sublimes at 349° C. (660.2° F.) in yellow rhombic scales, which become red on cooling. Mercuric iodide is a dimorphous substance, having a different crystalline form in its red and yellow states. According to Schiff, it is only in its yellow form that it is soluble in alcohol; hence it is that, when separated by water from its alcoholic solution, it falls in this condition. (*Ann. Ch. Ph.*, cix, 371.) It forms definite compounds with the iodides of the alkali metals. The compound formed with potassium iodide has been used as a medicine. (See *Mercuric Potassium Iodide* T.S. Part III.)

"Red Mercuric Iodide is a scarlet-red, amorphous powder, odorless, nearly tasteless, and permanent in the air. Red Mercuric Iodide is almost insoluble in water; 1 Gm. dissolves in 115 mils of alcohol, 910 mils of chloroform, and in 120 mils of ether at 25° C. (77° F.); also in 20 mils of boiling alcohol; soluble in solutions of the soluble iodides, mercuric chloride, sodium thiosulphate, and hot solutions of the alkali chlorides. When heated to about 150° C. (302° F.) the salt becomes yellow, but again assumes a red color on cooling; upon further heating, it fuses to a dark yellow liquid which, on cooling, forms a yellow, crystalline mass; at higher temperatures it is finally volatilized, leaving not more than 0.2 per cent. of residue. Heat the salt with potassium hydroxide T.S., and add a little sugar of milk; the compound is reduced and metallic mercury is precipitated. Boil about 0.1 Gm. of the salt with 2 mils of potassium hydroxide T.S., filter and supersaturate the filtrate with nitric acid. The liquid becomes yellow from the liberation of iodine which produces a blue color upon the addition of a few drops of starch T.S. Agitate thoroughly about 0.5 Gm. of Red Mercuric Iodide with 10 mils of distilled water and filter; the filtrate does not become more than slightly colored by hydrogen sulphide T.S. (*soluble mercury salts*). Two Gm. of Red Mercuric Iodide dissolves quickly in 100 mils of distilled water, containing 2 Gm. of potassium iodide, without leaving more than 0.004 Gm. of insoluble matter.

Assay.—Red Mercuric Iodide, when previously dried to constant weight in a desiccator over sulphuric acid and assayed by the Electrolytic method (see Part III, Test No. 4) shows not less than 99 per cent. of HgI_2." *U. S.*

"A crystalline powder of a vermilion color, becoming yellow when heated to about 150° C. (302° F.). Almost insoluble in *water*, sparingly soluble in *alcohol* (90 per cent.), freely and entirely soluble in *ether* (absence of mercurous iodide), and in *solution of potassium iodide*. Yields the *reactions* characteristic of mercuric salts and of iodides. Volatilises at a temperature under redness, leaving not more than a trace of fixed residue. When 0.5 gramme is well shaken with 10 millilitres of *water* and filtered, the filtrate is not colored more than slightly brown by *hydrogen sulphide* (limit of mercuric chloride), and does not become more than opalescent on the addition of *solution of silver nitrate* (limit of chlorides)." *Br.*

Uses.—Mercuric iodide resembles corrosive sublimate in its activities and therapeutic uses. Like the chloride it is an intense local irritant and is capable of giving rise to violent gastro-enteritis. It is also an active germicide, although its sparing solubility has to a large extent prevented its practical employment. The double iodide of potassium and mercury has, however, been recommended as a practical disinfectant. As an internal remedy mercuric iodide is employed especially in old obstinate cases of *syphilis*, and those attended with rheumatoid pains, or *diseases of the bones*.

Cazenave considers mercuric iodide to be the best topical application in *lupus*. He applies it in thin layers, every six or eight days, to small portions of the ulcerated surface at a time, in the form of a caustic ointment, made of equal parts of the iodide, oil, and lard. The application produces severe pain, and gives rise to a sharp inflammation, which soon terminates, leaving the ulcer in an improved condition, with a tendency to cicatrize smoothly and on a level with the surrounding skin. A solution of mercuric iodide in olive oil (1 in 5000), which is to be prescribed as an external application, has been prepared by Delacour. (See *J. P. C.*, 1903, 603; 1904, No. 2.)

Dose, one-twentieth to one-twelfth of a grain (0.003–0.005 Gm.).

HYDRARGYRI OXIDUM FLAVUM.
U. S., Br.

YELLOW MERCURIC OXIDE **Hydrarg. Oxid. Flav.**

(hȳ-drär′gy-rī ŏx′ĭ-dŭm flā′vŭm)

"It contains, when dried to constant weight at 150° C. (302° F.), not less than 99.5 per cent. of HgO (216.60). Preserve it in well-closed containers, protected from light." *U. S.*

"Yellow Mercuric Oxide may be obtained by the interaction of aqueous solutions of mercuric chloride and sodium hydroxide. It contains not less than 99.3 per cent. of pure mercuric oxide, HgO." *Br.*

Yellow Oxide of Mercury; Hydrargyrum Oxidatum Flavum vel præcipitatum; Precipitated Oxide of Mercury Mercuric Oxide; Oxyde Mercurique jaune, *Fr. Cod.*; Oxide de Mercure jaune ou précipité, *Fr.*; Hydrargyrum oxydatum via humida paratum, *P. G.*; Präcipitirtes (Gelbes) Quecksilberoxyd, *G.*; Ossido mercurico giallo, *It.*; Oxido mercurico amarillo, *Sp.*

No process is given in the U. S. P. IX or

British Pharm. (1914) for this salt. The U. S. P. VIII process was as follows:

"Corrosive Mercuric Chloride, *one hundred grammes* [or 3 ounces av., 231 grains]; Sodium Hydroxide, *forty grammes* [or 1 ounce av., 180 grains]; Distilled Water, *a sufficient quantity.* Dissolve the Corrosive Mercuric Chloride in *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of warm Distilled Water, and filter the solution. Dissolve the Sodium Hydroxide (which should contain at least 90 per cent. of pure, anhydrous sodium hydroxide) in *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of cold Distilled Water, and into this solution pour gradually, and with constant stirring, the solution of Corrosive Mercuric Chloride. Allow the mixture to stand for an hour at a temperature of about 30° C. (86° F.), stirring frequently. Then decant the supernatant, clear liquid from the precipitate, and wash the latter repeatedly by the addition and decantation of portions of Distilled Water, using *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of Water each time. Collect the precipitate on a strainer, and continue the washing with warm Distilled Water, until a small portion of the washings, when poured on a little mercuric chloride test solution, no longer produces a yellowish turbidity at the line of contact of the two liquids. Then allow the precipitate to drain, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.), and keep it in well-stoppered bottles, protected from light."

The process formerly adopted for this preparation was that of Hoffmann. The United States Pharmacopœia directed the alkaline solution in excess, and the addition of the corrosive sublimate to the alkali. Both these points are important, for if the corrosive sublimate be in excess, brown oxychloride will be formed towards the last of the decomposition, and when the alkali is added to the solution of corrosive sublimate, the same compound will be formed from the first, and is with difficulty decomposed by an excess of alkali. The solution of sodium hydroxide should be as free as possible from carbonate, to prevent the formation of brown mercuric carbonate. The mercuric chloride is precipitated by the sodium hydroxide, sodium chloride being left in solution. The object of the subsequent washing is to remove the sodium chloride and the excess of the alkali. The process was improved in the 1890 revision (and the improvement retained in the 8th Rev.) through the use of a freshly made solution of sodium hydroxide; the official "solution of potassa" used in the U. S. P. 1880 process invariably contained potassium carbonate, except when it was freshly made, and the presence of carbonate gave the mercuric oxide a reddish-brown tint which was very objectionable.

Properties.—The official mercuric oxide is of a yellow color similar to that of the yolk of egg, and is a completely amorphous powder, exhibiting no evidence of crystalline particles even under the microscope. Yellow mercuric oxide differs from the red only by being amorphous and in a much more minute state of division, the red oxide by trituration acquiring an orange and finally a yellow color. In consequence of its different state of aggregation, it is much more quickly acted on by reagents than is the red oxide. Thus, oxalic acid, which acts slowly on the red oxide, combines with the yellow oxide at lower temperatures, producing the white oxalate, and while the latter oxide, in contact with chlorine, gives up oxygen to that element, forming hypochlorous acid and corrosive sublimate, the former exercises scarcely any influence on the gas at common temperatures. It is described in the U. S. Pharmacopœia as "a light orange-yellow, amorphous, heavy, impalpable powder; odorless, and having a somewhat metallic taste; permanent in the air, but turning darker on exposure to light. Yellow Mercuric Oxide is almost insoluble in water; insoluble in alcohol; readily dissolved by diluted hydrochloric or nitric acid, forming colorless solutions. When moistened with hot distilled water, Yellow Mercuric Oxide is not alkaline to litmus. When moderately heated, Yellow Mercuric Oxide assumes a red color. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized, leaving not more than 0.2 per cent. of residue. A solution of 0.5 Gm. of Yellow Mercuric Oxide in 25 mils of either diluted hydrochloric or diluted nitric acid is not more than slightly turbid. Heat 0.5 Gm. of Yellow Mercuric Oxide for two hours in a test tube, on a water bath, with a solution of 1 Gm. of oxalic acid in 10 mils of distilled water and 1 mil of ammonia water, replacing from time to time the water lost by evaporation; it is converted into white or yellowish-white mercuric oxalate (distinction from *red mercuric oxide*).

"Assay.—Dissolve about 0.5 Gm. of Yellow Mercuric Oxide, previously dried to constant weight at 150° C. (302° F.) and accurately weighed, in 10 mils of distilled water, and 5 mils of nitric acid, and further dilute the solution with 150 mils of distilled water. Then add 2 mils of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium sulphocyanate V.S. to the production of a permanent yellowish-red color. It shows, in the dried Oxide, not less than 99.5 per cent. of HgO.

"Each mil of tenth-normal potassium sulphocyanate V.S. used corresponds to 0.01083 Gm. of HgO. Each gramme of Yellow Mercuric Oxide, previously dried to constant weight, corresponds to not less than 91.9 mils of tenth-normal potassium sulphocyanate V.S.

"Yellow Mercuric Oxide, previously dried to constant weight, may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"A yellow powder; insoluble in *water;* readily soluble in *hydrochloric acid,* the solution yielding the *reactions* characteristic of mercuric salts. When 1 gramme is shaken with 5 millilitres of

water for five minutes, the mixture is neutral to *litmus*. When gently heated it assumes a red color. The solution obtained by dissolving 0.5 gramme in 2 millilitres of *nitric acid* and diluting with 20 millilitres of *water* requires not less than 45.8 millilitres of *N/10 solution of ammonium thiocyanate* to produce a permanent pink coloration, *solution of ferric sulphate* being used as indicator. Heated to incipient redness it is resolved into oxygen and the vapor of mercury, leaving not more than 0.5 per cent. of fixed residue." *Br.*

I. Comere explains in a paper in *Répert. de Pharm.*, 1881, 199, the various conditions and modifications in the process necessary to make the oxide vary in color. (*N. R.*, 1882, 149.)

Uses.—The attention which has been paid to the yellow oxide is owing to its peculiar applicability to the local treatment of diseases of the eye, in consequence of its amorphous character. B. Squire of England, was the first to notice publicly this use of the oxide. (*P. J.*, 2d ser., vi, 512.) At present the yellow oxide is very largely used by oculists throughout the world in *conjunctivitis, hordeolum,* and other inflammations of the eye. The red oxide, however carefully it may be triturated, even though in a perfectly impalpable state, still shows under the microscope crystalline particles, which in contact with the conjunctiva cause more or less irritation; it can, therefore, be readily understood that, in the ordinary mode of preparing it for use as an ointment, it may sometimes be productive of serious annoyance. From this objection the yellow oxide is exempt. The yellow oxide is also used largely in various *skin diseases,* notably *eczema* of the external auditory canal.

HYDRARGYRI OXIDUM RUBRUM. U. S., Br.

RED MERCURIC OXIDE Hydrarg. Oxid. Rub. [Red Precipitate]

(hȳ-drär'gy-rī ŏx'ĭ-dŭm rŭ'brŭm)

"It contains, when dried to constant weight at 150° C. (302° F.), not less than 99.5 per cent. of HgO (216.60). Preserve it in well-closed containers, protected from light." *U. S.* "Red Mercuric Oxide may be obtained by heating mercurous nitrate until acid vapors cease to be evolved. Contains not less than 99.3 per cent. of pure mercuric oxide, HgO." *Br.*

Peroxide of Mercury, Red Oxide of Mercury; Hydrargyri Nitrico-oxydum, Mercurius Corrosivus Ruber vel Præcipitatus, Oxydum Hydrargyricum; Oxyde mercurique rouge, *Fr. Cod.;* Deutoxyde ou Péroxyde de Mercure, Précipité rouge, Poudre de Jean de Vigo, *Fr.;* Hydrargyrum Oxydatum, *P. G.;* Quecksilberoxyd, Rother Praecipitat, Quecksilber Præcipitat, Rothes Quecksilberoxyd, *G.;* Ossido mercurico rosso, *It.;* Oxido mercurico rojo, *Sp.*

Neither Pharmacopœia gives at present an official process for this oxide. The U. S. P. 1870 and the British Pharm. (1885) gave the following processes:

"Take of Mercury *thirty-six troyounces;* Nitric Acid *twenty-four troyounces;* Water *two pints.* Dissolve the Mercury, with the aid of a gentle heat, in the Acid and Water previously mixed, and evaporate to dryness. Rub the dry mass into powder, and heat it in a very shallow vessel until red vapors cease to rise." *U. S.* 1870. "Take of Mercury, by weight, *eight ounces* [avoirdupois]; Nitric Acid *four fluidounces and a half* [Imperial measure]; Water *two fluidounces* [Imp. meas.]. Dissolve half the Mercury in the Nitric Acid diluted with the Water, evaporate the solution to dryness, and with the dry salt thus obtained, triturate the remainder of the Mercury until the two are uniformly blended together. Heat the mixture in a porcelain dish, with repeated stirring, until acid vapors cease to be evolved." *Br.* 1885.

In this process the mercury is dissolved by the nitric acid, forming either mercuric nitrate, or a mixture of this with mercurous nitrate. The resulting mass when exposed to a strong heat is decomposed, giving out red nitrous fumes, and assuming successively a yellow, an orange, and a brilliant purple-red color, which becomes orange-red on cooling. These changes are owing to the gradual separation and decomposition of the nitric acid, by the oxygen of which the mercurous oxide, if any be present, is converted into mercuric oxide, while nitrogen dioxide gas escapes, and becomes nitrogen tetroxide on contact with the air. The mercuric oxide is left behind, but in general not quite free from the nitrate, which cannot be wholly decomposed by heat without endangering the decomposition of the oxide itself, and the volatilization of the metal.

The preparation is still frequently called by its older name, *red precipitate.* The name of *red mercuric oxide* is appropriate and more definite.

In the preparation of this mercurial, various circumstances influence the nature of the product, and must be attended to, if it is desired to procure the oxide with that fine bright orange-red color, and shining scaly appearance, usually considered desirable. Among these circumstances is the condition of the mercuric nitrate submitted to calcination. According to Gay-Lussac, it should be employed in the form of small crystalline grains. If previously pulverized, as directed in some of the official processes, it will yield an orange-yellow powder; if it be in the state of large and dense crystals, the oxide will have a deep orange color. Care must be taken that the mercury and acid be free from impurities. It is highly important that sufficient nitric acid be employed fully to saturate the mercury. According to R. Dufass a mercuric oxide which combines the good properties of both red and yellow oxides, without any of their disadvantages, is obtained as follows: 125 Gm. of potassium carbonate and 500 Gm. of water are heated to boiling, and a solution of 100 Gm. of mercuric chloride in 1875 Gm. of water is slowly added under continued boiling. The resultant precipitate, after washing and drying, is obtained as an orange-

yellow crystalline powder. (*Süddeut. Apoth. Ztg.*, 1902, 836.) Payssé, who paid great attention to the manufacture of red precipitate, recommended 70 parts of nitric acid from 34° to 38° Baumé, to 50 parts of mercury. This, however, is an excess of acid. We have been told by a skilful practical chemist of Philadelphia that he has found, by repeated experiment, 7 parts of nitric acid of 35° Baumé to be sufficient fully to saturate 6 parts of mercury. Less will not answer, and more will be useless. It is not necessary that the salt should be removed from the vessel in which it is formed; it is even asserted that the product is always more beautiful when the calcination is performed in the same vessel. A glass flask may be used with a large flat bottom, so that an extended surface may be exposed and all parts heated equally. The metal and acid having been introduced, the flask should be placed in a sand bath, and covered with sand up to the neck. The solution of the mercury should be favored by a gentle heat, which should afterwards be gradually increased till red vapors appear, then maintained as equably as possible until these vapors cease and at last slightly elevated until oxygen gas begins to escape. This may be known by the increased brilliancy with which a taper will burn if placed in the mouth of the flask, or by its rekindling if partially extinguished. Too high a temperature must be carefully avoided, as it decomposes the oxide and volatilizes the mercury. At the close of the operation, the mouth of the vessel should be stopped, and the heat gradually diminished, the flask being still allowed to remain in the sand bath. These last precautions are said to be essential to the fine red color of the preparation. It is best to operate upon a large quantity of materials, as the heat may be thus more uniformly maintained. The former direction of the Br. Ph., to rub a portion of mercury with the nitrate before decomposing it, renders the process more economical, as the nitric acid, which would otherwise be dissipated, is thus employed in oxidizing an additional quantity of the metal. As the process is ordinarily conducted in laboratories, the mercuric nitrate is decomposed in shallow earthen vessels, several of which are placed upon a bed of sand, in the chamber of an oven or furnace, provided with a flue for the escape of the vapors. Each vessel may convently contain ten pounds of the nitrate. There is always loss in the operation thus conducted. Egeling states that this oxide can be prepared by precipitation so that the resulting product cannot be distinguished from that made by ignition. Into a boiling solution of mercuric chloride (1:5) a boiling concentrated solution of potassium hydroxide is poured, until the dark brown color of the oxychloride is changed to a bright red, and the liquid reacts faintly alkaline; this is poured into 20 volumes of boiling water, and the precipitate collected, washed and drained. (*Ph. Ztg.*, 92, 517.) (For a process for *Hydrargyrum præcipitatum per se, precipitate per se,* or *calcined mercury,* all practically identical with red mercuric oxide, see *U. S. D.*, 17th ed., 704.)

Properties.—Red mercuric oxide, well prepared, has a brilliant red color, with a shade of orange, a shining scaly appearance, and an acrid taste. It is very slightly soluble in water, of which Barker found 1000 parts to take up 0.62 of the oxide. Christison found 1 part of the oxide to be dissolved by about 7000 parts of boiling water, and the solution to give a black precipitate with hydrogen sulphide. Tannic acid precipitates metallic mercury from an aqueous solution of the oxide, especially when heated. (Bullock, *Proc. A. Ph. A.*, 1858, p. 306.) It is insoluble in cold alcohol and ether. (*Ibid.*) Nitric and hydrochloric acids dissolve it without effervescence.

"Red Mercuric Oxide occurs as heavy, orange-red, crystalline scales, or as a crystalline powder, acquiring a yellow color when finely divided; odorless and having a somewhat metallic taste, permanent in the air. Red Mercuric Oxide is almost insoluble in water; insoluble in alcohol; readily dissolved by diluted nitric acid, or by hydrochloric acid. When heated to about 400° C. (752° F.), Red Mercuric Oxide becomes dark violet or almost black, but assumes its original color on cooling. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized without leaving more than 0.2 per cent. of residue. A solution of 0.5 Gm. of Red Mercuric Oxide in 25 mils of either hydrochloric or nitric acid is not more than slightly turbid. Heat 0.5 Gm. of Red Mercuric Oxide for two hours, in a test tube on a water bath, with a solution of 1 Gm. of oxalic acid in 10 mils of distilled water and 1 mil of ammonia water, replacing, from time to time, the water lost by evaporation; it will not change color within two hours (distinction from *yellow mercuric oxide*). Mix 1 Gm. of Red Mercuric Oxide with 5 mils of distilled water, add 2 mils of sulphuric acid, cool the mixture and carefully pour upon it 2 mils of ferrous sulphate T.S.; no brown zone develops at the line of contact (*nitrate*).

"Assay.—Dissolve about 0.5 Gm. of Red Mercuric Oxide, previously dried to constant weight at 150° C. (302° F.) and accurately weighed, in 10 mils of distilled water and 5 mils of nitric acid, and further dilute the solution with 150 mils of distilled water. Then add 2 mils of ferric ammonium sulphate T.S., and titrate with tenth-normal potassium sulphocyanate V.S. to the production of a permanent yellowish-red color. It shows, in the dried Oxide, not less than 99.5 per cent. of HgO.

"Each mil of tenth-normal potassium sulphocyanate V.S. used corresponds to 0.01083 Gm. of HgO. Each gramme of Red Mercuric Oxide, previously dried to constant weight, corresponds to not less than 91.9 mils of tenth-normal potassium sulphocyanate V.S.

"Red Mercuric Oxide, previously dried to constant weight, may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"Orange-red powder, or crystalline scales. Insoluble in *water;* soluble in *hydrochloric acid,* the solution yielding the *reactions* characteristic of mercuric salts. Gently heated it becomes dark violet, but resumes its orange-red color on cooling. Heated in a dry test-tube it does not evolve orange fumes (absence of nitrates). Responds to the quantitative test described under 'Hydrargyri Oxidum Flavum.' Heated to incipient redness it is resolved into oxygen and the vapour of mercury, leaving not more than 0.3 per cent. of fixed residue." *Br.*

Uses.—This preparation is too harsh and irregular in its operation for internal use, but is still employed externally as a stimulant and escharotic in the state either of powder or of ointment, although to a great extent supplanted by the yellow oxide. The powder is sprinkled on the surface of *chancres,* and *indolent, flabby,* or *fungous ulcers.* The powder should be finely levigated.

Hydrargyri Oxidum Nigrum, U. S. 1850. *Black Mercurous Oxide.*—This preparation has been dropped from both Pharmacopœias, and is now very rarely used. For a full account of its preparation, uses, and properties, see *U. S. D.,* 14th ed., 1256.

Off. Prep.—Unguentum Hydrargyri Oxidi Rubri, *N. F., Br.*

HYDRARGYRI SALICYLAS. U. S.

MERCURIC SALICYLATE Hydrarg. Salicyl. [Mercuric Subsalicylate]

(hȳ-drär'gy-rī săl-ĭ-cȳ'lăs)

"A compound of mercury and salicylic acid containing not less than 54 per cent. nor more than 59.5 per cent. of Hg. Preserve it in well-closed containers protected from light." *U. S.*

Mercuric salicylate is a compound of more or less varying chemical composition, having the approximate formula:

$$HgC_6H_4OCOO = 336.63.$$

It is neither a normal salicylate nor a true subsalicylate as will be seen by the above formula which shows the mercury replacing both the phenolic and carboxylic hydrogen.

It is usually prepared by effecting a combination between freshly precipitated yellow mercuric oxide and salicylic acid in the presence of moisture and with gentle heating.

It is readily dissolved by solutions of alkalies which form double salts with it and from which solutions it is reprecipitated upon the addition of acids. It is decomposed by strong mineral acids.

This salt was made official in the U. S. P. IX. It is officially described as follows:

"Mercuric Salicylate is a white, slightly yellowish or slightly pinkish powder; odorless and tasteless. Mercuric Salicylate is nearly insoluble in water or alcohol; dissolved by solutions of the fixed alkalies or their carbonates; dissolved by warm solutions of the alkali halides with the formation of double salts. Heat about 1 Gm. of the salt with 10 mils of hydrochloric acid; a solution is obtained from which salicylic acid separates on cooling. A piece of copper foil added to a portion of the filtered solution, nearly neutralized with ammonia water, immediately becomes coated with metallic mercury. To another portion of this solution add a few drops of ferric chloride T.S.; a violet color is produced. Incinerate about 0.5 Gm. of the salt in a porcelain crucible; not more than 0.2 per cent. of residue remains. The salt does not redden moistened blue litmus paper (*free salicylic acid*). No dark color results at once on shaking about 0.1 Gm. of the salt with 5 mils of hydrogen sulphide T.S. (*foreign mercury compounds*). About 0.2 Gm. of the salt dissolves completely in 4 mils of normal sodium hydroxide V.S.

"**Assay.**—Digest about 0.5 Gm. of Mercuric Salicylate, accurately weighed, in 15 mils of sulphuric acid and 10 mils of nitric acid on a water bath until dissolved. Cool the solution, dilute it with 150 mils of distilled water, add 30 mils of solution of hydrogen dioxide and mix well. Now add gradually, with constant stirring, 5 mils of diluted hypophosphorous acid, then 5 Gm. of sodium chloride, dissolved in 20 mils of distilled water, stir thoroughly and allow the mixture to stand until the precipitate has subsided. Filter and wash the precipitate with distilled water. Transfer the precipitate and filter to a flask, add 50 mils of tenth-normal iodine V.S. and 2 Gm. of potassium iodide, agitate the mixture until all of the precipitate has dissolved and titrate the excess of tenth-normal iodine V.S. with tenth-normal sodium thiosulphate V.S. It shows not less than 54 per cent. nor more than 59.5 per cent. of Hg.

"Each mil of tenth-normal iodine V.S. corresponds to 0.02006 Gm. of Hg. Each Gm. of Mercuric Salicylate corresponds to not less than 26.9 mils nor more than 29.7 mils of tenth-normal iodine V.S.

"Mercuric Salicylate may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

Uses.—Mercuric Salicylate is used chiefly in the treatment of *syphilis,* especially by intramuscular injection. The advantages claimed for it are that it is locally non-irritant and that it does not salivate. The first of these is due to its insolubility and the second is an evidence of its slow absorption. Nelson and Anderson (*J. A. M. A.,* 1915, lxv, 1905) reach the conclusion that, although there may be a subsidence of the objective manifestations of *syphilis* under the use of mercuric salicylate, the drug does not exercise a real curative effect. Mercuric salicylate is also used locally for its germicidal effect either as a dusting powder in the strengths of ten per cent., or as an injection in *gonorrhea,* one part of the drug being suspended in 300 of mucilage. It is also said to be a useful local application in *alopecia* of syphilitic origin.

For intramuscular injection a ten per cent. suspension in sterile liquid petrolatum may be employed. Of this ten minims (0.6 mil) may be injected deeply into the muscles of the back or buttocks, under strict asepsis, two or three

times a week. It has also been used by mixing with an equal part of potassium carbonate and dissolving in distilled water.

Dose by mouth, one-twelfth to one-third grain (0.005–0.021 Gm.).

HYDRARGYRUM. U. S., Br.

MERCURY Hydrarg. [Quicksilver]

(hȳ-drär′gy-rŭm)

"It contains not less than 99.5 per cent. of Hg (200.6). Preserve it in strong, well-closed containers." *U. S.* "Mercury is a liquid metal which may be obtained from native mercuric sulphide." *Br.*

Hydrargyrum Vivum, Mercurius Vivus, Argentum Vivum, Mercure Purifié, *Fr. Cod.*; Vif Argent, *Fr.*; Hydrargyrum, *P. G.*; Quecksilber, *G.*; Mercurio, *It., Sp.*

Mercury is found pure, forming an amalgam with silver, in the form of chloride (native calomel), but most abundantly as the sulphide or native cinnabar. Mines of this metal are found at Almaden in Spain, at Idria in Carniola, in the former duchy of Deux-Ponts, in Belluno, a province of Venetia, in Corsica, in the Philippine Islands and China, near Huancavelica in Peru, near Azogue in Colombia, at Durango in Mexico, at Yulgilbar, New South Wales, at New Almaden, New Idria, and other localities in Santa Clara County, California, about sixty-six miles from San Francisco, and in Brewster and other counties in Texas. The most ancient mine is that of Almaden in Spain, which was worked before the Christian era. This mine, and the mines of California, are the most productive at the present day, the Spanish mine yielding about three and a quarter millions of pounds, and the California mines about two-thirds of this amount annually. The ore in all the mines mentioned is cinnabar. The cinnabar from old Almaden is of a dull-red color in mass, of a dull brick-red color when in fine powder, and of the sp. gr. 3.6. That from New Almaden is of a bright-red color, slightly inclining to purple, not so hard as the Spanish ore, of a brilliant vermilion color in powder, and of the sp. gr. 4.4. The California cinnabar is richer in mercury, because purer, than the Spanish, the former yielding about 70 and the latter about 38 per cent. of mercury, according to the analysis of Adam Bealey. The California mine had been long known to the Indians, but its commercial value was first made known about 1843, by a Mexican, named Castillero, who became its first owner. At present it is in the hands of Americans. Ruschenberger has detected selenium in California cinnabar.

Extraction.—Mercury is obtained almost exclusively from the sulphide or native cinnabar. It is extracted by two principal processes. According to one process, the mineral is picked, pounded, and mixed with lime. The mixture is then introduced into cast iron retorts, which are placed in rows, one above the other, in an oblong furnace, and connected with earthenware receivers one-third full of water. Heat being applied, the lime combines with the sulphur, so as to form calcium sulphide and sulphate, while the mercury distils over, and is condensed in the receivers. The other process is practised at Almaden in Spain. Here a square furnace is employed, the floor of which is pierced with many holes, for the passage of the flame from the fireplace beneath. In the upper and lateral part of the furnace, holes are made, communicating with several rows of *aludels*, formed of adapters passing into one another, which terminate in a small chamber that serves both as condenser and receiver. The mineral, having been picked by hand and pulverized, is kneaded with clay, and formed into small masses, which are placed on the floor of the furnace. Heat being applied, the sulphur burns, and the volatilized mercury passes through the aludels to be condensed in the chamber.

Mercury, as found in commerce, is contained in cylindrical wrought iron bottles, called flasks, each containing 75 pounds. The United States production for 1916 was 28,942 flasks mainly in California, the world's production for 1913 is given as 124,654 flasks, Spain, Italy, Austria-Hungary, and the United States being the chief producers. The world's production at present is about 9,500,000 pounds. The exports are made principally to China, Mexico, Chili, and Peru. The chief uses of the metal are in mining silver and gold, in preparing vermilion, in making thermometers and barometers, in silvering looking glasses, and in forming various pharmaceutical compounds.

Properties.—Mercury is "a shining, silver-white metal; liquid at ordinary temperatures and easily divisible into spherical globules. When cooled to about –40° C. (–40° F.), it forms a ductile, malleable mass. It is without odor or taste. Specific gravity: about 13.5 at 25° C. (77° F.). Mercury is insoluble in the ordinary solvents, also in concentrated hydrochloric acid and, at ordinary temperatures, in sulphuric acid, but it dissolves in the latter when boiled with it, and is readily and completely dissolved by nitric acid. At ordinary temperatures Mercury volatilizes very slowly, but more rapidly as the temperature increases, and at about 358° C. (676.4° F.) it boils and is volatilized, yielding not more than 0.02 per cent. of residue. When globules of Mercury are dropped upon white paper, they roll about freely, retaining their globular form, and leaving no streaks or traces. Mercury must be perfectly dry and present a bright surface even after agitation in contact with air.

" Assay.—Dissolve about 0.4 Gm. of Mercury, accurately weighed, in a mixture of 10 mils of distilled water and 10 mils of nitric acid, warm the solution gently until red fumes cease to be evolved and the solution is colorless, and add 150 mils of distilled water. Then add 2 mils of ferric ammonium sulphate T.S. and titrate with tenth-normal potassium sulphocyanate V.S. to the production of a permanent, yellowish-red

color. It shows not less than 99.5 per cent. of Hg.

"Each mil of tenth-normal potassium sulphocyanate V.S. used corresponds to 0.01003 Gm. of Hg. Each gramme of Mercury corresponds to not less than 99.2 mils of tenth-normal potassium sulphocyanate V.S.

"Mercury may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"A silver-white, heavy liquid with a metallic lustre; easily divisible into globules. Readily volatilises when heated, leaving no appreciable fixed residue (absence of metallic and other impurities)." *Br.*

When perfectly pure it undergoes no alteration by the action of air or water, but in its ordinary state suffers a slight tarnish. When heated to near the boiling point, it gradually combines with oxygen, and is converted into mercuric oxide; but at the temperature of ebullition it parts with the oxygen with which it had combined, and is reduced again to the metallic state. It boils at 358° C. (676.4° F.), yielding a colorless vapor, and congeals at –39.4° C. (–39° F.), forming a malleable solid of tin-white color. It is a good conductor of heat, and its specific heat is small. It is not attacked by hydrochloric acid, nor by cold sulphuric acid; but boiling sulphuric acid or cold nitric acid dissolves it, producing mercurous sulphate and mercurous nitrate, respectively, with the liberation, in the former case, of sulphurous acid; in the latter, of nitrogen dioxide. Its combinations are numerous, and many of them constitute important medicines. It forms two series of compounds, the *mercurous* compounds containing the atom Hg^{I}, and the *mercuric* compounds containing the atom Hg^{II}.

Mercury, as it occurs in commerce, is in general sufficiently pure for pharmaceutical purposes. Occasionally it contains foreign metals, as lead, tin, zinc, and bismuth. Brande informs us that in examining large quantities of this metal in the London market he found it in only one instance intentionally adulterated. When impure, the metal has a dull appearance, leaves a trace on white paper, is deficient in due fluidity and mobility, as shown by its not forming perfect globules, is not totally dissipated by heat, and when shaken in a glass bottle coats its sides with a pellicle, or if very impure, deposits a black powder. If agitated with strong sulphuric acid, the adulterating metals become oxidized and dissolved, and thus the mercury may to a limited extent be purified. Lead is detected by shaking the suspected metal with equal parts of acetic acid and water, and then testing the acid by sodium sulphate or potassium iodide. The former will produce a white, the latter a yellow, precipitate, if lead be present. Bismuth is detected by dropping a nitric solution of the mercury, prepared without heat, into distilled water, when bismuth subnitrate will be precipitated. The complete solubility of the metal in nitric acid shows that tin is not present, and, if hydrogen sulphide does not act upon hydrochloric acid previously boiled upon the metal, the absence of contaminating metals is shown. Mercury may be purified by digesting it with a small portion of weak nitric acid, or with a solution of mercuric chloride, whereby all the ordinary contaminating metals will be removed. It may also be purified by distillation. For further details regarding the purification of mercury, see *U. S. D.*, 19th edition, p. 635.

Mercury is detected with great delicacy by Smithson's process, which consists in the use of a plate of tin, lined with one of gold, in the form of a spiral. When immersed in a mercurial solution, this galvanic combination causes the precipitation of the mercury on the gold, which consequently contracts a white stain. In order to be sure that the stain is caused by mercury, the metal must be volatilized in a small tube, so as to obtain a characteristic globule. Danger and Flandin have improved on Smithson's process. (See *Chem. Gaz.*, No. 61, p. 191.) A minute portion of any of the preparations of mercury, either in the solid state or in concentrated solution, being placed on a bright plate of copper, and a drop of a strong solution of potassium iodide added, a silvery characteristic stain will immediately appear on the copper.

For further details regarding the detection of mercury in compounds or preparations containing it, see *Hydrargyri Chloridum Corrosivum.*

It is difficult to accurately weigh small specified quantities of metallic mercury. An ingenious method was suggested by H. Kral, which is as follows: It consists of using a goose quill, into which the necessary quantity of mercury has been weighed. A small hole is then cut immediately above the surface of mercury, and the apparatus is ready for use. By simply immersing it into the bottle containing the mercury, it is filled through the opening, and uniform quantities, sufficiently accurate for practical purposes, are thus easily measured. (*Ph. Centralh.*, 1895, 422, 423.) In pharmaceutical operations a medicine dropper may be used to transfer the mercury.

Uses.—Metallic mercury in bulk is not absorbable, but when in a finely divided condition or in combination as a salt, it is taken up from the alimentary tract. In what form it is absorbed is at present uncertain. There are two widely held views, one that it is converted into an albuminate which is soluble in an excess of protein matter, and the other that it forms in the intestinal tract an oxide which is dissolved by the fatty matters. After its absorption it escapes from the system chiefly through the kidneys, although it has been detected in practically every secretion of the body. The elimination is comparatively slow so that when used over long periods of time it tends to accumulate in the system and may be stored up in the body for long periods. When present in the blood in large amounts it acts as a local irritant to vari-

ous glandular structure and leads to an increased secretion. The salivary glands are usually the most sensitive so that ptyalism is an early symptom of chronic mercurial poisoning, but both the kidney and bowels are frequently affected.

The effects of small quantities of mercury on the bodily functions are not positively known but it appears to act somewhat like arsenic, restraining destructive metabolism and thereby causing a tendency to increase in weight. A stimulating effect upon the blood making organs is often manifest by an increase in the number of red blood cells, but after toxic doses anemia may result apparently through destruction of the bone marrow. After large doses there is also a diminution in the fibrin content of the blood. Whether this latter change is caused by therapeutic quantities is at present uncertain, but the clinical effects seen in conditions attended with fibrinous exudate would lead one to believe that it does.

In the form of blue mass (see page 688) and of calomel (see page 557), mercury is used as a cathartic and in the latter form also as a diuretic. All of the soluble salts appear to be more or less actively germicidal, the bichloride being the most widely employed. In this place will be considered the effects of mercury upon the system which are common to all the preparations used internally.

The most marked constitutional effects from mercury are seen in *syphilis*. Its beneficial action in this affection is due to a direct toxic effect upon the spirochetes which are the cause of the disease. Under full mercurialism the obvious lesions of lues may disappear with great rapidity, but some of the germs remain hidden, so to speak, in the internal organs, especially in the central nervous system, and it is usually essential that the administration of mercury be continued for from one to two years. The generally accepted mode of using the metal is to give it in ascending doses until a mild degree of ptyalism is produced, then withdraw the metal for a few days to allow the system to clear itself of the excess and give it in doses just below that which caused salivation. In inflammatory diseases of the serous membranes, as *pleurisy, meningitis,* and *iritis,* especially when there is fibrinous exudate, mercury is often of the utmost value. In similar conditions involving mucous membranes—especially *enteritis*—while it appears to exercise more or less antiphlogistic action, its effects are much less striking.

The first observable signs of mercury inducing ptyalism are a coppery taste in the mouth, a slight soreness of the gums, and an unpleasant sensation in the sockets of the teeth when the jaws are firmly closed. Shortly afterwards the gums begin to swell, a line of whitish matter is seen along their edges, and the breath is infected with a peculiar and very disagreeable odor, called the mercurial fetor. The saliva at the same time becomes increased in quantity and more viscid, and, if the affection proceed, the gums, tongue, throat, and face become much swollen; ulcerations attack the lining membrane of the mouth and fauces; the jaws become excessively painful; the tongue is coated with a thick whitish fur, and the saliva flows in streams from the mouth.

If the use of the metal be persisted in, as was formerly sometimes the custom, the devitalized tissue affording a favorable place for bacterial growth, extensive necrosis may follow. In the treatment of *ptyalism* it should be remembered that the inflammation of the salivary glands is the result of an effort at excretion and those drugs, such as potassium iodide, which tend to hasten the elimination of the metal will aggravate the symptoms. The most important element of the treatment is local cleanliness. Antiseptic and astringent mouth washes should be frequently used and ulcerated spots may be touched with solutions of silver nitrate. If the flow of saliva is excessive full doses of atropine may be given.

In the foregoing observations we have described the ordinary effects of mercury, but occasionally, in peculiar constitutions, its operation is quite different, being productive of a dangerous disturbance of the vital functions. Pearson gave a detailed account of this occasional peculiarity in the operation of mercury, in his work on venereal diseases. The symptoms which characterize it are a small and frequent pulse, anxiety about the præcordia, pale and contracted countenance, great nervous agitation, and alarming debility. Their appearance is the signal for discontinuing the mercury, as a further perseverance with it might be attended with fatal consequences. Mercury occasionally produces a peculiar eruption of the skin, which is described by writers under the various names of *hydrargyria, eczema mercuriale,* and *lepra mercurialis.* Those who work in mercury, and are, therefore, exposed to its vapor, such as looking-glass silverers, and quicksilver miners, are injured seriously in their health, and not unfrequently affected with shaking palsy, attended with vertigo and other cerebral disorders. The miners are often salivated.

Many plants, exposed to the influence of the vapor spontaneously rising from mercury in confined air, perish in a few days, while if sulphur be placed by the side of the metal no effect of the kind is experienced. (Boussingault, *J. P. C.,* Sept., 1867, p. 176.) A probable inference from this fact is that workmen necessarily exposed to the vapor of mercury might be protected by the presence of sulphur in sufficient quantity.

Mercury has in the past been given in the metallic state, in the quantity of a pound or two, in *obstruction of the bowels,* to act by its weight; but the practice is of doubtful advantage.

HYDRARGYRUM AMMONIATUM.
U. S., Br.

AMMONIATED MERCURY Hydrarg. Ammon. [White Precipitate]

(hȳ-drär′gy-rŭm ąm-mō-nī-ā′tŭm)

"It contains mercurammonium chloride [$HgNH_2Cl = 252.09$] corresponding to not less than 78 per cent. nor more than 80 per cent. of Hg. Preserve it in well-closed containers, protected from light." *U. S.*

Hydrargyri Præcipitatum Album; Hydrargyrum Amidatobichloratum (ammoniato-muriaticum), Mercurius Præcipitatus Albus; Hydrargyri Ammonio-Chloridum; Ammoniochloride of Mercury, Mercuric Ammonium Chloride; Mercuric amido-chloride; Chloramidure de Mercure, Oxychlorure Ammoniacal de Mercure, Lait Mercuriel, Mercure Précipité Blanc, *Fr.;* Hydrargyrum praecipitatum album, *P. G.;* Weisser Quecksilberpräcipitat, Quecksilber-Chloridamid, *G.;* Cloramiduro di mercurio, *It.*

"Mercuric Chloride, 60 *grammes;* Solution of Ammonia, 80 *millilitres;* Distilled Water, *a sufficient quantity.* Dissolve the Mercuric Chloride in *twelve hundred millilitres* of Distilled Water with the aid of heat; pour the liquid into the Solution of Ammonia diluted with *four hundred millilitres* of Distilled Water, constantly stirring; collect the precipitate on a filter; wash it with *two hundred and fifty millilitres* of Distilled Water, and dry at a temperature not exceeding 30° C. (86° F.)." *Br.*

No process was recognized by the U. S. P. IX, but the U. S. P. VIII process was as follows:

"Corrosive Mercuric Chloride, in powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Ammonia Water, Distilled Water, each, *a sufficient quantity.* Dissolve the Corrosive Mercuric Chloride in *two thousand mils* [or 67 fluidounces, 5 fluidrachms] of warm Distilled Water, filter the solution, and allow it to cool. Pour the filtered liquid gradually, and with constant stirring, into *one hundred and fifty mils* [or 5 fluidounces, 35 minims] of Ammonia Water, taking care that the latter shall remain in slight excess. Collect the precipitate on a filter, and, when the liquid has drained from it as much as possible, wash it with a mixture of *four hundred mils* [or 13 fluidounces, 252 minims] of Distilled Water and *twenty mils* [325 minims] of Ammonia Water. Finally, dry the precipitate between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.), and keep it in well-stoppered bottles, protected from light."

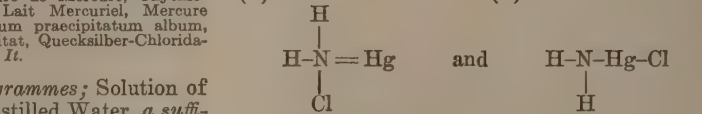
The British Pharmacopœia directs the preparation of white precipitate by precipitating a solution of mercuric chloride by ammonia. When ammonia, in slight excess, is added to a cold solution of mercuric chloride, ammonium chloride is formed in solution, and the white precipitate of the Pharmacopœias thrown down. The precipitate is usually washed with distilled water until the washings cease to give evidence of the presence of a chloride by producing a precipitate with silver nitrate acidulated with nitric acid. The white precipitate forms according to the following reaction:

$$HgCl_2 + 2NH_3 = NH_4Cl + NH_2HgCl$$

In other words, one molecule of the mercuric chloride reacts with two of the ammonia, and yields one molecule of ammonium chloride and one of *mercur-ammonium chloride,* or white precipitate. The commercial varieties have at times differed somewhat from the present official preparation in composition, the formula being $N_2H_5HgCl_2$ (or *Mercur-diammonium chloride*). (See paper by F. X. Moerk, *A. J. P.,* 1888.)

Of the two possible formulas illustrated by the following:

(1) (2)



Saha and Choudberry (*Ztschr. Anorg. Chem.,* 1914, 86, 225) concluded that the second formula is the only tenable one, agreeing with certain experiments by which derivatives were formed.

Properties.—"Ammoniated Mercury occurs as white, pulverulent pieces, or as a white, amorphous powder, without odor, and having an earthy, afterwards styptic and metallic taste; permanent in the air. Ammoniated Mercury is insoluble in water or alcohol. By prolonged washing with water it is gradually decomposed, assuming a yellow color, and becoming converted into a basic salt. Readily dissolved by warm hydrochloric, nitric, or acetic acid, and by a cold solution of ammonium carbonate. Also completely dissolved by a cold solution of sodium thiosulphate, with the evolution of ammonia; when this solution is heated for a short time, red mercuric sulphide is separated, which, on protracted boiling, turns black. At a temperature below a red heat, Ammoniated Mercury is decomposed without fusion, and at a red heat it is volatilized without leaving more than 0.2 per cent. of residue. When heated with potassium hydroxide T.S., the salt turns yellow, and evolves ammonia. A solution of the salt in diluted nitric acid yields with potassium iodide T.S. a red precipitate soluble in an excess of the reagent. With silver nitrate T.S. its nitric acid solution yields a white precipitate. The salt is completely soluble in hydrochloric acid (*mercurous salts*) without effervescence (*carbonates*)." *U. S.*

"**Assay.**—Dissolve about 0.5 Gm. of Ammoniated Mercury, accurately weighed, in 2 mils of hydrochloric acid and 10 mils of distilled water, warming gently until solution is effected, then dilute with 300 mils of distilled water and proceed as directed under *Hydrargyri Chloridum Corrosivum,* page 552, beginning with the word

'Pass' on line 6 of the Assay. The weight of mercuric sulphide obtained when multiplied by 0.862 indicates its equivalent in mercury (Hg) which corresponds to not less than 78 per cent. nor more than 80 per cent. of Hg.

"Each gramme of Ammoniated Mercury corresponds to not less than 0.9047 Gm. nor more than 0.9279 Gm. of mercuric sulphide.

"Ammoniated Mercury may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"A white, heavy, tasteless powder; insoluble in *alcohol* (90 per cent.) or *ether;* slowly decomposed by *water*. Digested with *solution of sodium hydroxide* it evolves ammonia, acquiring a pale yellow color, and the liquid, filtered and acidified with *nitric acid,* yields a white precipitate with *solution of silver nitrate*. Boiled with *solution of stannous chloride* it becomes grey, and yields globules of metallic mercury. Volatilises without fusing when sufficiently heated, leaving no appreciable fixed residue. When 0.3 gramme is triturated in a glass mortar with a few drops of *water,* and transferred to a flask with the aid of 40 millilitres of *water,* the mortar being finally rinsed with a solution of 2 grammes of *potassium iodide* in 10 millilitres of *water* and the rinsings added to the contents of the flask, then, the flask being securely closed and rotated frequently until solution is complete, the liquid thus obtained requires for neutralisation not less than 22.5 millilitres of *N/10 solution of hydrochloric acid, solution of methyl orange* being used as indicator (presence of not less than 94.5 per cent. of mercuric-ammonium chloride, NH_2HgCl)." *Br.*

Adulteration with white lead, chalk, or calcium sulphate may be detected by exposing a sample to a strong red heat, when these impurities will remain. Should starch be mixed with it, a charred residue will be obtained on the application of heat. Lead or starch may be found by digesting it with acetic acid, and testing the acetic solution with the compound solution of iodine, which will give a yellow precipitate if lead and a blue one if starch be present. The absence of mercurous compounds is shown by its not being blackened when rubbed with lime water.

Uses.—Ammoniated mercury is used only as an external application. It is a valuable remedy in parasitic skin diseases, such as *ringworm* or *favus,* and is also employed for destruction of *lice*. Mercur-diammonium chloride is said to produce an ointment more translucent and less white than the genuine, and more apt to become yellow on being kept. (J. Borland, *P. J.*, Dec., 1867, p. 262.)

Ammoniated mercury has been swallowed by mistake. It is highly poisonous, producing gastric pain, nausea, and purging. For recovery after taking half a drachm, see *L. L.,* July 4, 1857. The remedies employed were an emetic of zinc sulphate and milk.

Off. Prep.—Unguentum Hydrargyri Ammoniati, *U. S., Br.*

HYDRARGYRUM CUM CRETA.
U. S., Br.

MERCURY WITH CHALK Hydrarg. c. Cret.

(hȳ-drär'gy-rŭm cŭm crē'tą)

"It contains not less than 37 per cent. nor more than 39 per cent. of Hg." *U. S.*

Gray Powder; Æthiops Cretaceus; Mercure avec la Craie, Poudre de Mercure crayeux, *Fr.;* Quecksilber mit Kreide, *G.*

* "Mercury, *thirty-eight grammes* [or 1 ounce av., 150 grains]; Clarified Honey, *ten grammes* [or 154 grains]; Prepared Chalk, *fifty-seven grammes* [or 2 ounces av., 5 grains]; Water, *a sufficient quantity,* to make *one hundred grammes* [or 3 ounces av., 231 grains]. Weigh the mercury and clarified honey successively into a strong bottle of the capacity of *one hundred mils* [or 3 fluidounces, 183 minims], and add *two mils* [or 32 minims] of water. Cork the bottle, and shake it for about half an hour at a time, until the aggregate time of shaking reaches ten hours, or until the globules of mercury are no longer visible under a lens magnifying *four diameters*. The shaking may be more conveniently performed by mechanical means. Rub the prepared chalk with water, in a mortar, to a thick, creamy paste, and, having added the contents of the bottle, wash out the last portions with a little water, triturate the whole to a uniform mixture. Finally, dry the mixture, first between ample layers of bibulous paper, and afterwards in a dish at the ordinary temperature, until it weighs *one hundred grammes* [or 3 ounces av., 231 grains]. Then reduce it to a uniform powder, without trituration, and keep it in well-closed containers, protected from light." *U. S.*

"Mercury, 20 *grammes;* Prepared Chalk, 40 *grammes*. Triturate together in a porcelain mortar until the mixture acquires a uniform grey color and metallic globules cease to be visible to the naked eye." *Br.*

Dr. E. R. Squibb suggested the present official method of making mercury with chalk. The process is termed "succussion." When mercury is triturated with certain dry and pulverulent substances, such as chalk or magnesia, it gradually loses its fluidity and metallic luster and becomes a dark-gray powder. A similar change takes place when it is rubbed with viscid or greasy substances, such as honey or lard. The globules disappear, so as in some instances not to be visible even through a good lens, and the mercury is said to be *extinguished*. It was formerly thought that the metal was oxidized in the process. At present the change is generally ascribed to the mechanical division of the metal, which in this state is supposed to be capable of acting on the system with greater energy. There is good reason, however, to believe that in this, as in all the analogous preparations of mercury in which the metal is extinguished by trituration, a very small portion is converted into mercurous oxide, while by far the greater part remains in the metallic state.

Mercury with chalk is officially described in

the U. S. P. IX as "a light gray, rather damp powder, free from grittiness, without odor, and having a slightly sweet taste. Digest 0.1 Gm. of the powder with 20 mils of warm acetic acid; the chalk dissolves with effervescence, and a residue of finely divided mercury is left. On filtering this mixture, the filtrate becomes not more than slightly opalescent on the addition of a few drops of hydrochloric acid (*mercurous oxide*). Digest 0.1 Gm. of the powder with 20 mils of warm diluted hydrochloric acid and filter; the filtrate is not rendered more than slightly brown by hydrogen sulphide T.S. (*mercuric oxide*).

"**Assay.**—Dissolve about 1 Gm. of Mercury with Chalk, accurately weighed, in a mixture of 10 mils of distilled water and 10 mils of nitric acid and heat it on a water bath until red fumes cease to be evolved and the liquid becomes colorless. Then add 150 mils of distilled water and 2 mils of ferric ammonium sulphate T.S. and titrate the solution with tenth-normal potassium sulphocyanate V.S. It shows not less than 37 per cent. nor more than 39 per cent. of Hg.

"Each mil of tenth-normal potassium sulphocyanate V.S. used corresponds to 0.01003 Gm. of Hg. Each gramme of Mercury with Chalk corresponds to not less than 36.9 mils nor more than 38.9 mils of tenth-normal potassium sulphocyanate V.S.

"Mercury with Chalk may also be assayed by the Electrolytic method (see Part III, Test No. 4)." *U. S.*

"A light-grey powder, free from grittiness; tends to aggregate into minute globules. Insoluble in *water;* partially dissolved by *diluted hydrochloric acid,* the residual mercury being left in a finely divided state; the filtered liquid does not yield any white or grey precipitate on the addition of *solution of stannous chloride* (absence of mercuric compounds)." *Br.*

Robert B. Matter suggests an improved process for its preparation whereby labor and time are saved. It is as follows: "Mix twelve parts of finely powdered gum arabic with twelve parts of prepared chalk, triturate with sufficient water to form a rather thin paste, add thirty-eight parts of mercury, and continue the trituration until the globules of mercury have disappeared. Now add thirty-eight parts of finely powdered prepared chalk and sufficient water to form a thin paste, triturate, and when all the globules of mercury have disappeared, place the mortar in a hot water bath. The mixture distributed around the sides of the mortar will dry rapidly, when it can be easily scraped out, powdered in a clean mortar, passed through bolting cloth, or a fine sieve, and finally rubbed lightly in a clean dry mortar; 8 ounces may be made by this process in an hour." (*A. J. P.*, 1886, 119.)

Many modifications of the earlier processes suggested for the manufacture of this important preparation have appeared from time to time (see *U. S. D.*, 19th ed., p. 639), but the present official process is entirely satisfactory.

As found in commerce, mercury with chalk, instead of being the mild preparation intended, sometimes acts very harshly, causing vomiting, gastric pains, etc. This has been ascribed to the presence of antimony or arsenic, which, however, must be rare; the ordinary cause of the harshness is no doubt mercuric oxide, produced in minute proportion either during the trituration, or by the spontaneous change which occurs with time, mercurous oxide becoming mercuric oxide by the influence of light. The only sure method to guard against such results is to test the preparation carefully before dispensing it. (See *A. J. P.*, 1878, p. 325.) If the mercury contained in it be volatilized by heat, and the remaining chalk be dissolved by diluted acetic acid, the solution should not be colored by hydrogen sulphide. The presence of any probable metallic impurity may be detected in this way. To detect mercuric oxide, a portion of the powder may be treated with diluted hydrochloric acid with a moderate heat, and the solution tested by stannous chloride, which, if there be any mercuric oxide present, will cause a precipitation of metallic mercury as a black powder.

Uses.—Mercury with chalk is a very mild mercurial, similar in its properties to the blue mass, but much weaker. It is sometimes used as an alterative, particularly in the complaints of children attended with deficient biliary secretion, indicated by white or clay-colored stools. The chalk is antacid, and, though in small quantity, may sometimes be a useful accompaniment of the mercury in *diarrhea.* Eight grains of the U. S. preparation contain about three grains of mercury. It should not be given in pill with substances which become hard on keeping, as the contraction of the mass presses together the particles of mercury, which in time appear in globules in the interior of the pill.

Dose, as an alterative, one to three grains (0.06–0.2 Gm.); as a laxative, ten to twenty grains (0.65–1.3 Gm.).

HYDRASTINA. U. S.

HYDRASTINE

(hȳ-drăs-tĭ'nạ)

"An alkaloid [$C_{21}H_{21}O_6N = 383.18$] obtained from hydrastis or prepared synthetically. Preserve it in well-closed containers, protected from light." *U. S.*

Hydrastine, *Fr. Cod.;* Hydrastin, *G.*

Hydrastine may be obtained by exhausting the powdered root as far as possible with water by percolation, adding hydrochloric acid to the infusion so as to precipitate the berberine in the form of hydrochloride, and treating the mother liquor with solution of ammonia in slight excess. The hydrastine is precipitated, in an impure state, and may be purified by repeated solution in boiling alcohol, which deposits it in crystals on cooling. A little animal charcoal may be used towards the close of the process, in order to deprive the crystals completely of color. To Mahla, of Chicago, and Perrins, of London, is due the credit of having investigated this alka-

loid. The name hydrastine must not be confused with the similar name of the eclectic preparation called *hydrastin,* which is an almost inert preparation made by collecting, washing, and drying the precipitate produced by pouring a concentrated alcoholic solution of the drug into a large volume of water.

Properties.—"Hydrastine occurs in white to creamy white, glistening prisms or as a white, micro-crystalline powder; permanent in the air. Hydrastine is almost insoluble in water; 1 Gm. is soluble in 170 mils of alcohol, 1.4 mils of chloroform, and in 175 mils of ether at 25° C. (77° F.); also in 22 mils of alcohol at 60° C. (140° F.); freely soluble in benzene. Its saturated alcoholic solution is alkaline to litmus. It melts at about 131° C. (267.8° F.). Sulphuric acid produces a yellow color when added to Hydrastine; on heating the mixture, a purple color develops. Sulphuric acid containing 0.005 Gm. of molybdic acid in each mil gives with Hydrastine a green color, changing to olive-green and then to brown; nitric acid yields a reddish-yellow color; sulphuric acid containing 0.005 Gm. of selenous acid in each mil gives a light green color, changing to brown. No weighable ash remains on incinerating 0.1 Gm. of Hydrastine. A solution of about 0.1 Gm. of Hydrastine in 10 mils of diluted sulphuric acid shows no blue fluorescence (*hydrastinine*), but, on the gradual addition of potassium permanganate T.S., avoiding excess, a blue fluorescence develops. An aqueous solution of Hydrastine (1 in 20), made with the aid of a slight excess of diluted hydrochloric acid, is not reddened by chlorine water (*berberine*)." *U. S.*

Uses.—Hydrastine is an active alkaloid which is slowly absorbed and probably eliminated by the kidneys and lower bowel unchanged. When given to the lower animals it primarily stimulates the spinal motor cord, causing tetanic convulsions, with heightened reflexes, followed, if the dose has been large enough, by loss of reflex activity, and motor paralysis, which are probably in part due to depression of the motor centers, and are certainly, at least in part, the outcome of depression of the motor nerves and also of the muscles themselves. Death may occur in a convulsion from cramp-asphyxia, or later from simultaneous paralysis of the respiratory center and of the peripheral apparatus. The arterial pressure is first elevated and secondarily depressed; the first rise of pressure is probably due to the stimulation of the heart muscle, increasing the output of force, and of both the vasomotor centers and the muscle fibers in the arteriole coats, causing contraction of the blood vessels; the fall of pressure is the result of a direct paralytic action exerted upon the muscle fibers in the heart and in the arterioles. Hydrastine notably increases intestinal peristalsis, and, according to Fellner (*Arch. f. Gyn.,* 1906, lxviii), uterine contractions. It would seem to be a universal muscle poison, which acts upon both striated and non-striated muscle fibers in heart, arterioles, intestines, uterus, and generally throughout the body, its first stimulant action being followed by marked depression. Hydrastine has been shown by Fellner and Slavatinski to have a distinct ecbolic action, and premature labor is asserted to have been caused by its hypodermic administration. In practical medicine it is chiefly employed for the arrest of uterine hemorrhage, and in ordinary *menorrhagia.* When a prompt action is desired, a soluble salt like the hydrochloride should be administered hypodermically.

Dose, of pure hydrastine, one-sixth to one-half grain (0.01–0.032 Gm.).

HYDRASTINÆ HYDROCHLORIDUM. U. S.

HYDRASTINE HYDROCHLORIDE Hydrastin. Hydrochl. [Hydrastine Chloride]

(hȳ-drăs-tī'næ hȳ-drọ-ȼhlō'rī-dŭm)

"The hydrochloride [$C_{21}H_{21}O_6N.HCl$ = 419.65] of the alkaloid hydrastine. Preserve it in well-closed containers, protected from light." *U. S.*

Hydrastine hydrochloride was introduced in the U. S. P. IX to provide a soluble form of the alkaloid hydrastine.

"Hydrastine Hydrochloride occurs as a white to creamy-white powder, odorless, and hygroscopic. Hydrastine Hydrochloride is very soluble in water and in alcohol; slightly soluble in chloroform; very slightly soluble in ether. An aqueous solution of the salt (1 in 20) is neutral or only slightly acid to litmus. An aqueous solution of the salt (1 in 20) yields with silver nitrate T.S. a white precipitate, insoluble in nitric acid. In other respects the salt responds to the tests for identity and purity under *Hydrastina,* omitting the melting point." *U. S.*

Dose, one-sixth to one-half of a grain (0.01–0.03 Gm.).

Off. Prep.—Liquor Hydrastinæ Compositus, *N. F.*

HYDRASTININÆ HYDROCHLORIDUM. U. S.

HYDRASTININE HYDROCHLORIDE Hydrastinin. Hydrochl. [Hydrastininæ Hydrochloras, Pharm. 1890, Hydrastinine Hydrochlorate, Hydrastinine Chloride]

(hȳ-drăs-tī-nī'næ hȳ-drọ-ȼhlō'rī-dŭm)

"The hydrochloride [$C_{11}H_{11}O_2N.HCl$ = 225.57] of hydrastinine, an alkaloid obtained by the oxidation of hydrastine. Preserve it in well-closed containers, protected from light." *U. S.*

Hydrastininum hydrochloridum, *P. G.;* Hydrastininhydrochlorid, Salzsaures Hydrastinin, *G.*

Preparation.—*Hydrastinine* is an artificial alkaloid, produced by acting on hydrastine, the alkaloid from hydrastis, with oxidizing agents. When manganese dioxide and sulphuric acid are used together, or when platinic chloride is employed, hydrastinine and *opianic acid* are the products. Hydrastinine is also manufactured synthetically from berberine, from safrol, and from heliotropine.

Properties.—Hydrastinine hydrochloride is officially described as in "light yellowish needles, or as a yellowish-white, crystalline powder without odor. One Gm. of Hydrastinine Hydrochloride dissolves in 195 mils of chloroform, and in 1820 mils of ether at 25° C. (77° F.); very soluble in water and alcohol. Its aqueous solution (1 in 20) is neutral to litmus and shows a blue fluorescence, especially when highly diluted. It melts at about 210° C. (410° F.) with partial decomposition. In an aqueous solution of the salt (1 in 20), potassium dichromate T.S. produces a precipitate which redissolves if gently heated, but on cooling the solution it separates again in glistening needles. Silver nitrate T.S. produces in an aqueous solution of the salt a white precipitate, insoluble in nitric acid. No weighable ash remains on incinerating 0.1 Gm. of Hydrastinine Hydrochloride. In an aqueous solution of the salt (1 in 20) bromine T.S. produces a yellow precipitate, which is completely soluble in ammonia water, producing an almost colorless solution (*hydrastine*). Add a few drops of ammonia water to 1 mil of an aqueous solution of Hydrastinine Hydrochloride (1 in 20); no turbidity is produced (*foreign alkaloids*). Add slowly 4 or 5 drops of a solution of sodium hydroxide (1 in 7) to a solution of 0.2 Gm. of the salt in 3 mils of distilled water; each drop causes a milky turbidity, which disappears again on shaking (*foreign alkaloids*). From this solution, after standing for some time, pure white hydrastinine separates, and the supernatant fluid is almost colorless." *U. S.*

Uses.—Hydrastinine is, when given in large enough amount, a powerful depressant to the whole motor tract, affecting the psycho-motor centers of the cerebral cortex, the motor nerve, and the muscle itself. In the present state of our knowledge it is uncertain whether the depression is or is not preceded by a brief period of excitation, but it is almost certain that there is a primary stimulation of the muscles. The alkaloid slows the action of the heart but increases the force of the beat, and markedly augments the blood pressure, contracting actively the blood vessels by stimulating both the vasomotor centers and the muscles in the walls of the arterioles. In the toxic dose it finally paralyzes respiration, although there is reason for believing that in the beginning it stimulates the function. Death occurs from asphyxia, to which is usually ascribed the final fall of the arterial pressure.

It has a direct stimulant action upon the uterus. According to Kehrer (*Monatsschr. Geburtsh. u. Gynäk.*, 1907, xvi, p. 709), it rivals in the certainty of its effect the best preparations of ergot. It would seem that it is a universal muscle poison, primarily stimulant in its action, and that in this way it affects the heart, the arterioles, and the uterus. According to von Bunge, it markedly increases peristalsis, so that even the intestines do not escape its muscular action.

Hydrastinine was originally recommended by Falck in the treatment of *menorrhagia, metrorrhagia, dysmenorrhea,* and even *endometritis.* The testimony as to its value in all forms of uterine hemorrhage seems to be conclusive, and it is affirmed by many gynæcologists that it has a pronounced alterative influence upon the mucous membrane of the uterus. From our own experience we are convinced that it has value as a cardiac tonic, not equal in power or certainty of action to digitalis, but often useful as a substitute for that drug, especially in minor cases of heart failure. Its sedative action on the central nervous system, conjoined with its stimulating influence upon the circulation and its pronounced effects upon the genital system, make it a very valuable remedy in the treatment of feeble women of hysterical temperament, with tendency to uterine fluxes.

Dose, usually employed, from three-fourths of a grain to one and a half grains (0.048–0.096 Gm.) every three to six hours, but probably larger doses might often be used with advantage, since no ill effects have been as yet recorded as being produced by it. The salt may be given hypodermically.

HYDRASTIS. U. S. (Br.)

HYDRASTIS [Golden Seal]

(hȳ-drăs'tĭs)

"The dried rhizome and roots of *Hydrastis canadensis* Linné (Fam. *Ranunculaceæ*), without the presence or admixture of more than 2 per cent. of the stems, leaves or other foreign matter and yielding not less than 2.5 per cent. of the ether-soluble alkaloids of Hydrastis." *U. S.* "Hydrastis Rhizome is the dried rhizome and roots of Hydrastis canadensis, *Linn.*" *Br.*

Hydrastis Rhizoma, *Br.;* Hydrastis Rhizome; Rhizoma Hydrastis; Golden Seal, Yellow Root, Yellow Puccoon, Orange Root, Indian Dye, Indian Turmeric, Ohio Turmeric; Indian Paint, Ground Raspberry, Eye Root, Eye balm, Yellow Eye, Jaundice Root; Hydrastis, *Fr. Cod.;* Racine d'Hydrastis du Canada, Sceau d'or, *Fr.;* Canadische Gelbwurzel, Gelbes Blutkraut, *G.;* Idraste, *It.;* Hidrastis del Canada (Rhizoma de), *Sp.*

Hydrastis canadensis is a small, herbaceous, perennial plant, with a thick, fleshy, yellow rhizome, from which numerous long roots arise, and an erect, simple, pubescent stem, from six inches to a foot in height. There are usually but two leaves, which are unequal, one sessile at the top of the stem, the other attached to the stem a short distance below by a thick roundish footstalk, causing the stem to appear as if bifurcate near the summit. The leaves are pubescent, roundish-cordate, with from three to seven, but generally five, lobes, which are pointed and unequally serrate. A solitary flower stands upon a peduncle rising from the basis of the upper leaf. It is without corolla, but with a greenish-white calyx, the sepals of which closely resemble petals, and are very caducous, falling very soon after the flower has expanded. The fruit is a globose, compound, red or crimson berry, half an inch or more in diameter, composed of many fleshy carpels, each tipped with a short curved beak, and containing one or rarely two seeds. The

plant grows in moist, rich woodlands in most parts of the United States, and at one time abundantly in the North and West. The fruit bears a close resemblance to the raspberry, but is not edible. The root is the part used. The Indians employed it for staining and dyeing yellow under the name of *yellow puccoon*, and it is said to impart a rich and permanent yellow, and with indigo a fine green, to wool, silk, and cotton. There is but one other species of *Hydrastis* known—viz., *H. jezoensis* Sieb. et Zucc., which is found in Northern Japan.

Enormous quantities of hydrastis are consumed. It is estimated that between 200,000 and 300,000 pounds of the drug are annually used in medicine. As the natural supplies are becoming limited many experiments in the cultivation of hydrastis have been made. It can be grown from cuttings of the rhizome and from seed. It furthermore can be grown with the natural shade of the woodlands or by means of artificial shade. The important articles on the cultivation of hydrastis are the following: John Uri Lloyd, *Proc. A. Ph. A.*, 1905, p. 307, and in *A. Ph. A.*, vol. i, p. 5; Alice Henkel and G. Fred Klugh, *Circ. No. 6, Bureau of Plant Industry, U. S. Department of Agriculture;* J. C. Baldwin, *A. J. P.*, 1913, p. 147. Most of the commercial supplies are obtained from the Ohio Valley. The States producing hydrastis are West Virginia, Ohio, Kentucky and Indiana. The chief market being Cincinnati.

Properties.—The fresh rhizome is juicy, and loses much of its weight in drying. The drug is officially described as "rhizome horizontal or oblique, sub-cylindrical and usually more or less flexuous, from 1 to 5 cm. in length and from 2 to 7 mm. in diameter, occasionally with stem-bases; externally yellowish or grayish-brown, marked by numerous stem-scars and more or less annulate from scars of bud-scales, otherwise deeply longitudinally wrinkled; on the under and lateral portions arise numerous, long, filiform roots which are easily detached; fracture short, waxy; internally of a deep yellow color and consisting mostly of parenchyma enclosing an interrupted circle of small fibro-vascular bundles; odor distinctive; taste, bitter. Macerate the drug for a short time in water until it is softened, then make sections and mount them directly in sulphuric acid and examine under the microscope; in a short time numerous acicular or rod-shaped crystals separate, some attaining a length of 0.2 mm. The powder is brownish-yellow; starch grains numerous, from 0.002 to 0.015 mm. in diameter, mostly single, nearly spherical, and either free or in the parenchyma cells; fragments with the tissues of the fibro-vascular bundles mostly associated with starch-bearing parenchyma; tracheæ with simple and bordered pores and occasionally spiral thickenings, and associated with short sclerenchymatous fibers possessing thin walls with simple pores; occasional fragments of tabular cork cells with reddish-brown walls." *U. S.*

"Rhizome tortuous, simple or branched, from ten to forty millimetres long and from three to ten millimetres thick; yellowish-brown, becoming darker by age. On the upper surface, short ascending branches usually terminated by cup-shaped scars; on the lower surface and sides numerous thin, brittle roots. Fracture clean, resinous; fractured surface brownish-yellow or greenish-yellow. In transverse section, a ring of bright yellow, somewhat distant, wood-bundles. Slight but characteristic odor; taste bitter. Ash not more than 11 per cent." *Br.*

The color of the rhizome, though yellow in the recent root, becomes a dark yellowish-brown by age; that of the rootlets and the interior of the root is yellow, and that of the powder still more so.

Holm gives a valuable illustrated article on the morphology of the hydrastis plant in *Merck's Rep.*, xxii, p. 202. (See also *Chem. Zeit.*, 1894, p. 134.) Rosenthaler has extended his studies of microsublimates to that of hydrastis and finds that the pyroanalytical sublimate of hydrastis gives general alkaloidal reaction and a characteristic reaction with sulphuric acid. (*Apoth. Zeit.*, xxviii, p. 991.) Owing to the high price of hydrastis the quality of the commercial article has steadily deteriorated in recent years, and Lloyd asserts that every drug native to the soil which resembles this rhizome, either in fiber or in color, has been known to be mixed with it. (*Pharm. Rev.*, xxiii, p. 330.)

"**Assay.**—Introduce 10 Gm. of Hydrastis, in No. 60 powder, into a 250 mil flask and add 100 mils of ether and proceed as directed under *Belladonnæ Radix*, page 222, fourth line of the Assay, beginning with the word "Stopper." Modify the process there given by using 50 mils of the ether solution, representing 5 Gm. of Hydrastis, to complete the assay. Use ether instead of chloroform for the final shaking out of the alkaloids, and dry the residue to constant weight at 100° C. (212° F.) instead of titrating. The weight is the amount of ether-soluble alkaloids from 5 Gm. of Hydrastis." *U. S.*

The medicine imparts its virtues and coloring matters to water and alcohol. Examined by Alfred B. Durand of Philadelphia, it was found to contain albumen, starch, fatty matter, resin, yellow coloring matter, sugar, lignin, and various salts. He also discovered a peculiar nitrogenous, crystallizable substance, for which he proposed the name of *hydrastine*. (*A. J. P.*, 1851, p. 112.) It was also found that the root contained another alkaloid, to which it owes its yellow color. F. Mahla first ascertained that this alkaloid of hydrastis was *berberine*. (*Am. J. S.*, Jan., 1862, p. 43.) It exists in large proportion in hydrastis, constituting, according to Perrins, nearly 4 per cent. For a valuable paper by J. U. Lloyd on the preparation of salts of berberine, see *A. J. P.*, 1879, p. 11. Lerre's process based on Lloyd's for preparing hydrastine and berberine will be found in the *U. S. D.*, 19th ed., p. 643.

Wilhelm (*P. J.*, 1888, 325) furnishes a process for obtaining the alkaloids from hydrastis as follows. The extract obtained by treating the coarsely powdered root with water acidified with acetic acid at 37.8° C. (100° F.) is evap-

orated to a syrup and excess of diluted sulphuric acid added, when berberine sulphate separates. The filtrate neutralized with ammonia water gives a precipitate containing much hydrastine; this is separated, and on adding ammonia water in excess to the filtrate a further precipitate is produced, which contains *canadine.* Both precipitates, boiled with ethyl acetate, give solutions which, on cooling, deposit hydrastine in large crystals, somewhat colored, but rendered pure by recrystallization. The crystals from the second ammonia precipitate are much purer than those from the first; by slow evaporation of the ethyl acetate solution they can be obtained as large as walnuts.

A substance obtained by the precipitation of an infusion of the root by hydrochloric acid has been for some time known and used by the "Eclectics," under the name of *hydrastin;* it consists of a small proportion of hydrastine, with berberine and resin, and the reader must be cautious not to confound this substance with the alkaloid to which the name properly belongs. Perrins obtained 1.5 per cent. of the eclectic principle from the root, and, having given five grains of it to a rabbit without any other effect than a slight uneasiness which soon ceased, concluded justly that it was not poisonous.

Canadine ($C_{20}H_{21}NO_4$) was extracted by E. Schmidt; it occurs in the form of brilliant, small, white nodules, melting at 134° C. (273.2° F.). When canadine is dissolved in alcohol and treated with iodine, berberine hydriodide (which is yellow in color) is formed. Canadine was believed to be identical with dihydromethylberberine (*Ph. Post,* 1892, 230), and the formula $C_{21}H_{21}NO_4$ was given to it. E. Schmidt, however (*A. Pharm.,* 1894, 136–154), has found that its true formula is $C_{20}H_{21}NO_4$, and, owing to the fact that iodine forms with it berberine hydriodide, he believes that canadine is a *tetrahydroberberine.* Schmidt also obtained, as an additional product of the iodine reaction, the hydriodide of another base, which he believes is intermediate between berberine and canadine. For a process for isolating canadine, see *Proc. A. Ph. A.,* 1894, 1103. The alkaloid discovered by A. K. Hale, and obtained later by Burt and by Lerchen, and which was named *xanthopuccine,* is now considered to be identical with canadine. For processes for making hydrastine and berberine, see *D. C.,* 1897, 34. It is probable, from the odor of hydrastis, that besides the two alkaloids here mentioned it contains also an active volatile principle, but this has not yet been isolated.

LaWall (*Proc. Pa. Ph. A.,* 1912, p. 142) made separate assays of the rhizome and rootlets from a 98-pound lot of the drug. There was present 45.5 pounds of rhizome and 48 pounds of rootlets, the balance being dirt and waste. The rhizomes assayed 2.48 per cent. of hydrastine and the rootlets 1.38 per cent. The average of the entire lot was 1.92 per cent.

Uses.—Hydrastis owes its virtues almost entirely to hydrastine, the alkaloid berberine, aside from some effect as a bitter, being practically inert. It has enjoyed a widespread reputation as a local remedy in various forms of *catarrh,* such as *rhinitis, gastritis, vaginitis,* and *urethritis.*

In chronic or subacute *inflammations* of the *colon* and *rectum* injections of hydrastis are often of great service, and it has been used in *hemorrhoids* with asserted excellent results.

The strength of the local application of hydrastis to be used in various diseases of the mucous membrane varies from five to twenty-five per cent. of the fluidextract. In *gonorrhea* from forty to eighty minims (2.5–5.0 mils) of the fluidextract, may be used to the fluidounce (30 mils). In *hemorrhoids* from two to four drachms to the fluidounce may be used. The glycerite is not so useful a local preparation as the fluidextract diluted with water, a deposit of the insoluble resinous substance upon the mucous membrane and its constant prolonged influence being important.

The general action of hydrastis upon the system and internal uses are the same as those of hydrastine (see p. 571).

It is essential to recognize the differences, medicinally, between the preparations of hydrastis. The so-called *hydrastin* of commerce is really an impure body, containing berberine, canadine, hydrastine, and probably some resin. The *dose* of this hydrastin is from five to ten grains (0.32–0.65 Gm.).

There is some reason for believing that *berberine* has a special action upon the gastro-intestinal tract. Marfori has, however, found that even in large therapeutic dose it is without perceptible influence upon the circulation or the nervous system. When, therefore, a preparation of hydrastis is to be used for effects other than a local action on the gastro-intestinal or other mucous membrane, a salt of the pure alkaloid hydrastine should be used.

According to the studies of Falck and Guenste, berberine causes in dogs and rabbits restlessness, convulsive tremblings, hurried respiration, and diarrhea, followed, if the dose has been large enough, by decrease of the breathing rate, widespread paralysis, dyspnea, convulsions, and death. In man as yet no serious symptoms have been recorded as produced by it. Buchner is stated to have taken nearly twenty grains without causing anything more serious than a loose stool. Marek (*W. M. W.,* 1911, 2146) has presented evidence that it possesses valuable oxytocic properties, and is useful in *delayed labor.* It has been employed in internal medicine as a simple bitter, in doses of from two to five grains (0.13–0.32 Gm.).

Hydroberberine (Canadine), whose molecule contains four atoms of hydrogen more than the molecule of berberine, is said by Marfori to differ from berberine physiologically; it produces in moderate dose an increase in the blood pressure by stimulating the vasomotor center in the medulla. *Opianic, hydrastinic,* and *berberinic acids* are said by the same authority to be almost inert physiologically, except that they are feebly antiseptic. (*T. G.,* 1890.)

For a physiological study of the *methylamine* derivatives of hydrastine (*hydrastine methylamine*), see *V. A. P. A.*, cxlii, 1895.

Dose, of hydrastis, fifteen to thirty grains (1–2 Gm.).

HYOSCYAMINÆ HYDROBROMIDUM. U. S.

HYOSCYAMINE HYDROBROMIDE Hyoscyamin. Hydrobr. [Hyoscyaminæ Hydrobromas, Pharm. 1890, Hyoscyamine Hydrobromate, Hyoscyamine Bromide]

(hȳ-ǫs-cȳ-ą-mĭ'næ hȳ-drǫ-brō'mĭ-dŭm)

"The hydrobromide [$C_{17}H_{23}O_3N.HBr = 370.12$] of hyoscyamine, an alkaloid obtained from hyoscyamus and other plants of the *Solanaceæ*. Preserve it in well-closed containers, protected from light." *U. S.*

Hyoscyaminum Hydrobromicum; Bromhydrat d'Hyoscyamine, *Fr.;* Hyoscyaminhydrobromid, Bromwasserstoffsaures Hyoscyamin, *G.*

For discussion of the properties of hyoscyamine, see *Hyoscyaminæ Sulphas.*

Preparation.—This salt may be made by dissolving 10 Gm. of hyoscyamine in 11 Gm. of hydrobromic acid (25 per cent.), evaporating and crystallizing.

Properties.—Hyoscyamine hydrobromide is officially described in the United States Pharmacopœia IX as in "white, prismatic crystals without odor. It is deliquescent on exposure to the air. *Great caution must be observed in tasting it, using only a very dilute solution.* It dilates the pupil of the eye. One Gm. of Hyoscyamine Hydrobromide dissolves in 2.5 mils of alcohol, 1.7 mils of chloroform, and in 2260 mils of ether at 25° C. (77° F.); very soluble in water. Its aqueous solution (1 in 20) is neutral to litmus, and is strongly lævorotatory. It melts at about 152° C. (305.6° F.). Silver nitrate T.S., when added to an aqueous solution of the salt, yields a yellowish-white precipitate which is insoluble in nitric acid. Shake 2 mils of chloroform with 1 mil of an aqueous solution of the salt (1 in 10) to which a few drops of chlorine water have been added; the chloroform assumes a brownish color. Add about 0.01 Gm. of the salt to 5 drops of nitric acid, and evaporate to dryness in a porcelain dish; the residue yields a violet color upon the addition of alcoholic potassium hydroxide T.S. Gold chloride T.S., when added to an aqueous solution of the salt (1 in 20), yields a precipitate which, when recrystallized from a small quantity of boiling distilled water, acidulated with hydrochloric acid, is deposited on cooling in minute, lustrous, golden-yellow scales (difference from *atropine and scopolamine*). Platinic chloride T.S. does not form a precipitate in aqueous solutions of the salt (1 in 20) (difference from *most alkaloids*). No weighable ash remains on incinerating 0.1 Gm. of Hyoscyamine Hydrobromide. About 0.05 Gm. of the salt dissolved in 1 mil of sulphuric acid gives not more than a faint yellow color (*carbonizable impurities*)." *U. S.*

Uses.—The medicinal properties and the dose of this salt of hyoscyamine are precisely those of the sulphate, to which it is preferred by some.

Dose, one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.).

HYOSCYAMINÆ SULPHAS. Br.

HYOSCYAMINE SULPHATE

(hȳ-ǫs-cȳ-ą-mĭ'næ sŭl'phăs)

"Hyoscyamine Sulphate, $(C_{17}H_{23}O_3N)_2,H_2SO_4,2H_2O$, is the sulphate of an alkaloid, hyoscyamine, obtained from various plants belonging to the natural order Solanaceæ." *Br.*

Sulfate d'Hyoscyamine, *Fr.;* Hyoscyaminum Sulfuricum, Schwefelsaures Hyoscyamin, Hyoscyaminsulfat, *G.*

Hyoscyamine sulphate was deleted from the U. S. P. IX, but retained by the British Pharm. (1914).

Although Brandes announced the existence of an alkaloid in the seeds of *Hyoscyamus niger,* the process which he used to obtain it was not successful in other hands. The credit of first isolating the alkaloid *hyoscyamine* from the plant must be given to Geiger and Hesse, who obtained it as long ago as 1833. Höhn and Reichardt's process, in which the seed is used as the source, is as follows. They treat hyoscyamus seed first with ether to separate fatty matter, then with alcohol acidulated with a few drops of sulphuric acid, and afterwards distil the alcoholic solution. The aqueous residue is to be neutralized with sodium hydroxide, and the liquid precipitated by a solution of tannin. The precipitate, having been placed on a porcelain plate to dry, is mixed while yet moist with an excess of lime, and then exhausted by strong alcohol. The alcoholic solution is treated with sulphuric acid, then with sodium hydroxide, and finally with ether, which dissolves the liberated hyoscyamine. By distilling off the ether a colorless oleaginous liquid is left, which at length solidifies.

These investigators originally gave to hyoscyamine the formula $C_{15}H_{23}O_3N$, but Ladenburg later showed by a study of its decomposition products that it is isomeric with atropine, $C_{17}H_{23}O_3N$. Ladenburg made the most complete study of atropine and hyoscyamine that we have, and has established their relations to each other in a clear light. According to him (*Ber. d. Chem. Ges.,* xiii, pp. 251, 909, and 1549), hyoscyamus contains two alkaloids, a crystalline one, to which the name of *hyoscyamine* is given, and an amorphous one, which remains in the mother liquor after the removal of the crystallizable alkaloid, for which he proposed the name *hyoscine,* but which is now believed to be identical with scopolamine. Hyoscyamine treated with boiling baryta water assimilates a molecule of water and splits up into what were

called *hyoscinic acid,* $C_9H_{10}O_3$, and *hyoscine,* $C_8H_{15}ON$, but which Ladenburg showed to be identical with the decomposition products of atropine, *tropic acid* and *tropine.* Hyoscyamine is to-day regarded as a stereo-isomer of atropine, from which it differs in certain physical properties, notably in that it is lævorotatory to polarized light, while atropine is optically inert.

Hyoscyamine crystallizes in colorless, transparent, silky needles, fusing at 108.5° C. (227.3° F.), is inodorous, of an acrid, disagreeable taste, slightly soluble in water, very soluble in alcohol and ether, and volatilizable with little change if carefully distilled. It is quickly altered by contact with water and an alkali, and when heated with potassium or sodium hydroxide is completely decomposed, with the disengagement of ammonia. It neutralizes the acids, forming crystallizable salts, and is precipitated by infusion of galls. The alkaloid and its salts are very poisonous, and the smallest quantity, introduced into the eye, produces dilatation of the pupil, which continues long.

Hyoscine was first known in commerce as *amorphous hyoscyamine.* The best salts, according to Edlefsen, to prepare and dispense are the *hydrobromide* and *hydriodide,* the former of which is the one most frequently used. Hyoscine hydriodide crystallizes from water, in which it is only moderately soluble, in small, hemihedral prisms, which mostly have a slight yellowish color. (See *Scopolominæ Hydrobromidum.*)

The double gold chloride, $C_{17}H_{21}O_4NHCl + AuCl_3$, is less soluble than the corresponding gold salt of hyoscyamine, and so serves to separate them when together.

Properties.—The British Pharmacopœia describes hyoscyamine sulphate as "a deliquescent crystalline powder. Soluble in 0.5 part of *water.* Melting point from 203° to 204° C. (397.4°–399.2° F.). Yields the *reaction* characteristic of sulphates. When treated with *nitric acid* and *alcoholic solution of potassium hydroxide,* as described under 'Atropina,' a violet coloration is produced. 0.05 gramme, dissolved in 5 millilitres of *water* acidified with *hydrochloric acid,* yields with *solution of auric chloride* a yellow precipitate which, recrystallised from *water* acidified with *hydrochloric acid,* forms brilliant golden-yellow scales melting, when dried, at 165° C. (329° F.). Dissolves in *sulphuric acid* without coloration. No appreciable ash." *Br.*

Uses.—The physiological effects of hyoscyamine are qualitatively the same as those of its isomer atropine, although there is some difference quantitatively. Atropine, as pointed out on page 221, is regarded as a mixture of dextro and lævorotatory alkaloids. Cushny (*J. P.,* 1903, xxx, p. 177) has shown that the lævorotatory substance (hyoscyamine) is relatively more active in its paralyzing effect on nerve endings and less active in its stimulant action upon the central nervous system. Like atropine, hyoscyamine checks secretion by paralyzing the terminals of nerves to the various glands, dilates the pupil by paralyzing the ends of the oculomotor nerve, and increases the pulse rate by paralyzing the pneumogastrics. The rise in blood pressure is comparatively small after hyoscyamine because it exercises but a feeble influence on the vasomotor center, similarly it causes but little increase in the respiration and shows less tendency to cause delirium. The former belief that hyoscyamine possessed narcotic properties was doubtless due to its contamination with scopolamine; there is no convincing evidence that chemically pure hyoscyamine has a depressant action upon the cerebrum. Clinically, hyoscyamine may be substituted for atropine wherever the action on peripheral nerves is desirable, as for instance, to check excessive secretion, to dilate the pupil, or to allay intestinal spasm.

Dose, one two-hundredth to one one-hundredth of a grain (0.0003–0.0006 Gm.).

HYOSCYAMUS. U. S. (Br.)

HYOSCYAMUS Hyosc. [Henbane, Hyoscyami Folium P. I.]

(hȳ-ǫs-cȳ'ą-mŭs)

"The dried leaves or fruiting tops of *Hyoscyamus niger* Linné (Fam. *Solanaceæ*), yielding not less than 0.065 per cent. of the alkaloids of Hyoscyamus." *U. S.* "Hyoscyamus Leaves are the leaves of Hyoscyamus niger, *Linn.,* collected from the flowering plants, and dried." *Br.*

Hyoscyami Folia, *Br.;* Hyoscyamus Leaves, Henbane Leaves, Black Henbane; Stinking Nightshade, Insane Root, Poison Tobacco; Jusquiame noire, *Fr. Cod.;* Belene, Chenile, *Fr.;* Herba Hyoscyami, *P. G.;* Bilsenkraut, Bilsenkrautblätter, *G.;* Giusquiamo, *It.;* Beleno, *Sp.*

There are about eleven species of the genus *Hyoscyamus* known; these are distributed from the Canary Islands over Europe and Northern Africa to Asia.

Hyoscyamus niger, or *henbane,* is usually a biennial plant, with a long, tapering, whitish, fleshy, somewhat branching root, not unlike that of parsley, for which it has been eaten by mistake, with poisonous effects. The stem, which rises in the second year, is erect, branching, from one to four feet high, and thickly furnished with leaves. These are large, oblong-ovate, deeply sinuated with pointed segments, undulated, soft to the touch, and at their base embrace the stem. The upper leaves are generally entire. Both the stem and leaves are hairy, viscid, and of a sea-green color. The flowers form long, one-sided, leafy spikes, which terminate the branches, and hang downward. They are composed of a calyx with five pointed divisions, a funnel-shaped corolla, with five unequal, obtuse segments at the border, five stamens inserted into the tube of the corolla, and a pistil with a blunt, round stigma. The corolla is of an obscure yellow color, beautifully variegated with purple veins. The fruit is a globular two-celled capsule, covered with a lid, invested with the persistent calyx, and contains numerous small seeds, which are discharged by the horizontal separation of the lid. The whole plant has a rank, offensive odor.

H. niger is susceptible of considerable diversity of character, causing varieties which have by some been considered as distinct species. Thus, the plant is sometimes annual, the stem simple, smaller, and less downy than in the biennial plant, the leaves shorter and less hairy and viscid, and the flowers often yellow without the purple streaks.

The plant is found in the northern and eastern sections of the United States, occupying waste grounds in the older settlements, particularly cemeteries, old gardens, and the foundations of ruined houses. It is, not, however, a native of this country, having been introduced from Europe. In Great Britain, and on the continent of Europe, it grows abundantly along the roads, around villages, amidst rubbish, and in uncultivated places. Both varieties were formerly cultivated in England, but at present the biennial is chiefly or solely grown. The annual plant flowers in July or August, the biennial in May or June. For an account of the cultivation of the biennial variety of Hitchin, England, see *P. J.*, Feb., 1860.

Mitlacher, in connection with other plants, has carried on a series of experiments on the cultivation of Hyoscyamus and reports on the results of his work in *Ph. Post*, 1911, p. 390 and *Zeit. Oest. Apoth. Ver.*, 1912, p. 401. Hyoscyamus has been successfully grown in the testing gardens of the Bureau of Plant Industry. There is usually some difficulty in growing hyoscyamus owing to its destruction by insects (*A. J. P.*, 1912, p. 551), but Newcomb was very successful with his experiments in Minneapolis. (*A. J. P.*, 1914, p. 531.) Schneider also has pointed out that henbane thrives well in California and says that it no doubt will do well in the Coast valleys. (*Pac. Pharm.*, iii, p. 192.) Peckolt reports that *Hyoscyamus niger* grows wild in portions of Brazil. (*B. P. G.*, xix, p. 33.) Chevalier has shown that by cultivation the alkaloidal content of hyoscyamus can be increased to 0.286 per cent. of total alkaloids. (*C. R. A. S.*, 1910, p. 344.)

H. albus, so named from the whiteness of its flowers, is used in France indiscriminately with the former species, with which it appears to be identical in medicinal properties. *Hyoscyamus muticus* L., of Egypt, i said to grow luxuriantly in the temperate zone and to produce a very much larger proportion of total alkaloids than does the official English plant, although the relative proportions of hyoscine and hyoscyamine are not the same. It appeared in the London market in the form of broken stalks with a few capsular fruits and traces of leaves and may become an important source of the alkaloids to the manufacturers.

Properties.—All parts of *Hyoscyamus niger* are active. The official description of the plant is as follows: "Usually much wrinkled, with numerous stems and with the flowering or fruiting tops intermixed; leaves when entire attaining a length of 25 cm., a breadth of 10 cm., ovate or ovate-oblong, very inequilateral, the lower with short petioles, the upper sessile, summits acute, margins coarsely and angularly 1- to 4-toothed or lobed; grayish-green, glandular-hairy, particularly on the lower surfaces; flowers nearly sessile with an urn-shaped, unequally 5-toothed calyx and a campanulate corolla which in the fresh state is of a yellowish color; fruit a 2-locular pyxis, and enclosed in a large urn-shaped calyx with 5 acute teeth; odor heavy, distinctive; taste somewhat bitter and acrid. Stems from 3 to 10 cm. in length and from 2 to 5 mm. in thickness, nearly cylindrical or somewhat compressed, longitudinally wrinkled and hairy. The powder is grayish-green; under the microscope, it exhibits calcium oxalate crystals usually in the form of 4- to 6-sided, isolated prisms, sometimes in twins, from 0.015 to 0.025 mm. in length, also occurring in spherical aggregates either isolated or attached to the prismatic crystals, sometimes in rosette aggregates, 0.02 mm. in diameter, and occasionally in sphenoidal micro-crystals; hairs numerous, of two kinds; the non-glandular from 2 to 10 cells in length, the glandular with a 1- to many-celled head and a 1- to 4-celled stalk; fragments of epidermis with broadly elliptical stomata from 0.03 to 0.035 mm. in length and with 3 to 4 neighboring cells; fragments of tracheæ with simple or bordered pores and spiral or reticulate thickenings, also associated with sclerenchymatous fibers having thin porous walls and showing little or no lignification; pollen grains, nearly smooth and from 0.035 to 0.05 mm. in diameter. The presence of the leaves of *Hyoscyamus muticus* Linné in either the crude or powdered Hyoscyamus may be determined by the characteristic, branching, non-glandular hairs occurring on both the stems and leaves of that species. Hyoscyamus yields not more than 30 per cent. of ash." *U. S.*

"Pale green, varying in length but seldom exceeding twenty-five centimetres; mostly sessile; exstipulate, triangular-ovate or ovate-oblong, acute, undulated, irregularly toothed, sinuate or pinnatifid, with conspicuous midrib. On both surfaces, but particularly on the under surface and near the veins, long uniserial hairs terminating in pluricellular glands. In the mesophyll prismatic and cluster-crystals of calcium oxalate." *Br.*

Much of the efficacy of hyoscyamus depends upon the time at which it is gathered. The leaves should be collected soon after the plant has flowered. In the biennial plant, those of the second year are preferred to those of the first. The latter, according to Houlton, are less clammy and fetid, yield less extractive, and are medicinally much less efficient. It is said that the plant is sometimes destroyed by severe winters in England, and that no leaves of the second year's growth are then obtainable. This is, perhaps, one of the causes of the great uncertainty of the medicine as found in commerce. The root also is said to be much more poisonous in the second year than in the first.

"Assay.—Introduce 30 Gm. of Hyoscyamus, in No. 60 powder, into a 500 mil flask and add 300 mils of a mixture of 1 volume of chloroform and 2 volumes of ether. Stopper the flask,

shake it well, and allow it to stand for ten minutes; then add 5 mils of ammonia water and shake the flask vigorously every ten minutes during two hours. Now add 40 mils of distilled water, again shake the flask and when the drug has settled decant 200 mils of the solution, representing 20 Gm. of Hyoscyamus, and proceed as directed under *Belladonnæ Radix*, page 222, beginning with the word 'Filter' on twelfth line of the Assay. Before titration treat the residue twice with 5 mils of ether and evaporate to dryness each time. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the total alkaloids of Hyoscyamus." *U. S. IX.*

The recent leaves have, when bruised, a strong, disagreeable, narcotic odor, somewhat like that of tobacco. Their taste is mucilaginous and very slightly acrid. When dried, they have little odor or taste. Thrown upon the fire, they burn with a crackling noise, as if they contained a nitrate, and at the same time emit a strong odor.

Much of the henbane of commerce is taken from the plant in the first year of its growth. The drug of the market is very variable, frequently containing an excess of sand and the leaves of other species of hyoscyamus. A few years ago, it was admixed with *H. muticus*, a plant growing in Egypt. The latter is readily determined by the presence of characteristic branching non-glandular hairs which are found on both the stems and leaves. (See *A. J. P.*, 1908, p. 361 and Kraemer's *"Scientific and Applied Pharmacognosy."*)

Hyoscyamus is completely extracted by diluted alcohol. The aqueous infusion is of a pale-yellow color, insipid, with the narcotic odor of the plant. The leaves were analyzed by Lindbergsen, who obtained from them a narcotic principle. They contain a large proportion of potassium nitrate, F. Mahla having obtained, as nearly as he could estimate from his experiments, 2 per cent. of that salt. (*A. J. P.*, 1859, p. 402.) The seeds are very small, roundish, compressed, somewhat kidney-shaped, a little wrinkled, of a gray or yellowish-gray color, of the odor of the plant, and of an oleaginous, bitterish taste. Geiger and Hesse (1833) were the first to demonstrate the existence of an alkaloid in hyoscyamus. Ladenburg stated in 1880 that there are two alkaloids in the plant,—one crystallizable, *hyoscyamine*, and the other amorphous, *hyoscine* (scopolamine, p. 985). (See *Hyoscyaminæ Sulphas*, p. 575.) Höhn (*Ann. Ch. Ph.*, 157, 98) obtained from the seeds a bitter principle which proved to be a glucoside. He calls it *hyoscypicrin*, and gives it the formula $C_{27}H_{52}O_{14}$.

From experiments made by Hirtz upon the relative medicinal power of extracts from the seeds and from the leaves, he inferred that the former had ten times the strength of the latter. Henbane leaves yield, by destructive distillation, a very poisonous empyreumatic oil.

Uses.—Hyoscyamus combines the therapeutic actions of its two alkaloids, hyoscyamine and scopolamine. Because of the presence of the former it tends to check secretion and to relax spasm of the involuntary muscles, while through the narcotic effects of its scopolamine it lessens pain and exercises a slight somnifacient action. Its most important use is in relief of painful spasmodic affections of the unstriped muscle, as in *lead colic* and *irritable bladder*. It is also employed to allay nervous irritation, as in various forms of *hysteria* or *irritable cough*, but is inferior to scopolamine for these purposes. Externally cataplasms or fomentations of the fresh leaves have been employed to allay pain in *cancerous ulcers* and *hemorrhoids*, but its employment for this purpose is of doubtful advantage.

Hyoscyamus is preferably given in the form of the fluidextract or tincture. The inspissated juice of the fresh leaves (*Extractum hyoscyami viride*, Br.) is exceedingly variable in its operation and is not to be recommended.

Dose, of the leaves, two to five grains (0.13–0.32 Gm.).

HYPOPHYSIS SICCA. U. S.

DESICCATED HYPOPHYSIS Hypophysis Sic. [Desiccated Pituitary Body]

(hȳ-pŏph'-ȳ-sĭs sĭc'cą)

"The posterior lobe obtained from the pituitary body of cattle, cleaned, dried, and powdered." *U. S.*

The *Hypophysis cerebri*, or *pituitary body*, is a small bean-shaped body found within the skull in the depression known as the *sella turcica* or pituitary fossa. Its longest diameter is in the transverse direction and it consists of two distinct portions enclosed together in a connective-tissue capsule. The smaller, or anterior lobe, is composed of nerve cells similar to the gray matter of the brain and continuous with the *infundibulum* which forms a portion of the floor of the third ventricle of the brain. The *posterior lobe*, which is much larger, is made up of glandular epithelium and contains here and there collections of colloid material homologous to that found in the thyroid body. In the human being the pituitary body measures about 12 mm. transversely, 7 mm. longitudinally and 5 mm. vertically, and weighs from five to twenty grains. In cattle the organ has a weight of two or three drachms (7.7–11.6 Gm.). When dried it loses approximately three-fourths of its weight. In commerce it appears as "a yellowish or grayish, amorphous powder, having a characteristic odor. It is only partially soluble in water." *U. S.*

Because of our ignorance of the active principle of the hypophysis it is at present impossible to devise a process for chemical assay.

Of the various physiological tests which have been suggested, the only one which offers any promise of proving practically useful is that based upon the stimulant action on the uterus. This method has been favorably reported on by Heidelberg, Pittenger and Vanderkleed (*J. A. Ph. A.*, 1914, iii, p. 808), and by Roth (*Hygienic Laboratory Bull.* No. 100, November, 1914.) The method used is precisely the same as the isolated uterus test for ergot. (See p. 426.) For a standard Roth recommends *histamine*, which is generally efficient in the proportions of one to twenty million, but Heidelberg, Pittenger, and Vanderkleed prefer a standard solution of the pituitary body itself.

Uses.—The precise function of this body in normal animals is not known, although its removal causes profound alterations in the bodily function, prominent among which are overgrowth of the bones and deposit of fat. According to Cushny (*J. A. M. A.*, 1909, liii) the destruction of the anterior lobe is accompanied with glycosuria and subnormal temperature. Feeding the pituitary to normal animals causes an increase in the output of nitrogen, phosphorus, and lime. Because of the loss of the last two elements many writers have concluded that it hastens the bony catabolism.

In 1899 Schafer and Vincent (*J. P.*, 1899, xxv, 87) discovered that the injection of an aqueous extract of the hypophysis into the vein caused a rise of blood pressure rivalling that brought about by suprarenal extract in height and surpassing it in duration. The theory which was at one time advanced that the action of pituitary extract was similar to that of the suprarenal extract has been shown to be erroneous. The pressor principle is found only in the posterior lobe of the hypophysis, but the present evidence indicates that the anterior lobe is more important in its nutritive effects than the posterior.

The physiological effects of the posterior lobe of the pituitary body are stimulation of all the unstriped muscles, and increased secretion of the kidney and probably of the mammary glands. Among those muscles affected by the drug which are of importance from the standpoint of its clinical use, may be mentioned the circulatory, uterine, and intestinal muscles. The stimulant action upon the blood vessels is shown by the increase in arterial pressure which is apparently of purely vascular origin (Wiggers, *A. J. M. S.*, 1911, cxli, 142); the heart is not made up of unstriped muscle and does not appear to be stimulated by the drug. Repeated doses, even if intervals of an hour or two are allowed to elapse between their exhibition, do not produce the same degree of rise as the primary injection; indeed after a sufficient number of doses the drug exercises a depressor rather than a pressor influence. As was first shown by Ott and Scott (*Monthly Cyclopedia and Med. Bull.*, August, 1909), the extract of hypophysis is one of the most powerful and certain stimulants for the uterine muscle that we possess. While it does increase the tonus of this muscle it seems to be especially efficient to increase the vigor of individual contractions. The increase in the flow of urine seems to be the result of direct action upon the renal epithelium, for although the renal arteries are generally relatively dilated by the drug, Hoskins and Means (*J. P. Ex. T.*, 1913, iv, p. 435) have shown that there is no constant relation between the dilation of the renal artery and the degree of diuresis. It is probable, therefore, that the local widening of the vessels in the kidney is the result and not the cause of the increased functional activity of this organ, and the diuretic action is of the same type as that of caffeine.

The most common use of the hypophysis at present is as a uterine stimulant especially during *labor*. Although it is a very valuable drug in this condition when used circumspectly, there is no doubt that it is capable of doing great harm and has been greatly abused. While it seems less liable than ergot to cause tetanic spasm of the womb and there is therefore less danger of asphyxiation of the child (see Quigley, *J. A. M. A.*, 1915, lxiv, p. 1222), there have been reported several cases of rupture of the uterus from its injudicious use. Before the head has passed the pelvic outlet its use in general should be avoided, although occasional circumstances may indicate its use at an earlier stage. For the treatment of *postpartum hemorrhage* it has the great disadvantage that its effects last only from one to two hours and there appears to be a tendency towards secondary relaxation. The promptness of its action, however, renders it in some cases superior to ergot; the two drugs may often be exhibited simultaneously, the pituitary for its primary, quick effect and the ergot to maintain the action. It has also been used to control *menorrhagia* and *metrorrhagia*. The effect of the extract of hypophysis on blood pressure suggests its use for the treatment of *surgical shock*. Musser (*A. J. M. S.*, 1913, cxlvi, p. 208) has shown that even when exhibited by the mouth it causes a marked rise in blood pressure in human beings. There have been, however, comparatively few clinical reports of its use as a circulatory stimulant. As an intestinal stimulant it has been highly lauded by many surgeons for the prevention or treatment of post-operative paralysis of the bowel. As a diuretic, although classed by physiologists as one of the most potent stimulants to the kidney, it has failed to achieve wide popularity. The enormous increase in the secretion of milk which has followed its exhibition has naturally suggested its use as a lacteal stimulant both in human beings and also animals, but the present evidence seems to be that the primary stimulation is followed by a compensatory diminution of glandular activity. Among other conditions for which it has been recommended may be mentioned *Graves's disease, hay fever, rickets, acromegaly,* and *tetany*. Its value in these conditions, if it has any, is probably dependent upon its influence over the nutritive processes and the whole gland is preferable. When, however, the effect upon the in-

voluntary muscles is desired, whether of the uterus or arteries, we believe that the extract of the posterior lobe is to be preferred, since the anterior portion of the hypophysis has no effect upon these muscles and may exercise undesirable influences on the metabolism.

Dose, from one-half to three grains (0.032–0.2 Gm.).

Apozèmes, Tisanes, Infusions, *Fr.;* Infusa, *P. G.;* Infusionen, Aufgüsse, *G.;* Infusi, *It.;* Infusiones, *Sp.*

These are aqueous solutions obtained by treating with water (without the aid of ebullition), vegetable products only partially soluble in that liquid. The water employed may be hot or cold, according to the objects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance and macerating the mixture in a tightly closed vessel until the liquid cools. The soluble principles are thus extracted more rapidly, and, as a rule, in a larger proportion, than at a lower temperature. Some principles, moreover, are dissolved in this manner which are nearly or quite insoluble in cold water. A prolonged application of heat is in some instances desirable, and this may be effected by placing the vessel near the fire. Cold water is preferred when the active principle is highly volatile, when it is injured by heat, or when any substance of difficult solubility at a low temperature exists in the vegetable, which it is desirable to avoid in the infusion. A longer continuance of the maceration is necessary in this case, and in warm weather there is sometimes danger that spontaneous decomposition may commence before the process is completed. When a strong infusion is required, the process of *percolation* may be advantageously resorted to. The water employed should be free from saline impurities which frequently produce precipitates and render the infusion turbid. Fresh river, rain, or distilled water is usually preferable to water pumped from wells or obtained from springs, except when the latter are known to produce water which will not react with any of the constituents of the infusion.

The substance to be acted on should be sliced or bruised, or in the state of powder, but this last condition is seldom requisite, unless when percolation is employed, and is always inconvenient, as it requires that the infusion should be filtered through paper in order completely to separate the undissolved portion. In other cases it is sufficient to strain it through fine linen or muslin. When percolation is resorted to, the substance should be more or less finely powdered. The United States Pharmacopœia furnishes a general formula for infusions, which is to be used when the proportions are not specified. In the U. S. P., 1880, the strength of such infusions was fixed at 10 per cent. Experience has shown, however, that this was too strong for general purposes, and in the U. S. Pharmacopœia of 1890 and the Eighth and Ninth Revision, 5 per cent. has been chosen as the limit.

General Formula for Infusions, U. S. P. IX.

"Infusions must be *freshly made from the drugs,* and, when the strength of Infusions is not otherwise directed, they are to be prepared by the following general formula: The Drug, coarsely comminuted, *fifty grammes* [or 1 ounce av., 334 grains]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Introduce the substance into a suitable vessel provided with a cover, pour upon it *one thousand mils* [or 33 fluidounces, 6½ fluidrachms] of boiling water, cover the vessel tightly, and allow it to stand for half an hour. Then strain with expression, and pass enough water through the strainer to make the Infusion measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. If the activity of the Infusion is affected by heat, cold water only should be used.

"*Caution.*—The strength of Infusions of potent or very active drugs should be specially directed by the physician." *U. S.*

Infusions are usually prepared in glazed earthenware or porcelain vessels fitted with covers. Brande suggests the use of clean metallic vessels, which, when finely polished, retain the heat for a longer time, but they are more liable to chemical alterations, and may sometimes injuriously affect the preparation. Vessels of block-tin are generally well adapted for the purpose.

As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. In this country they are usually prepared in the patient's home, and the propriety of their introduction into the Pharmacopœia has been doubted, but it is desirable to have certain fixed standards for the regulation of the medical practitioner, and it is always preferable to direct infusions from the apothecary, for whose guidance official formulas are necessary. Physicians would, indeed, find an advantage in more frequently directing them to be prepared by the pharmacist, instead of leaving their preparation to the carelessness or want of skill of attendants upon the sick. Infusions may be kept during hot weather, and for many months, by straining them *while hot,* and pouring them at once into bottles provided with accurately ground stoppers. The bottle must be brim-full, the stopper being made to displace its bulk of the fluid. A common bottle with a cork stopper may be used, if the softened cork be forced into the full bottle, tied down, and at once dipped into hot sealing wax. The hotter the liquid and the freer from the air the better will the infusion keep. Sterilization of infusions by heating them to the boiling point, then preserving in bottles which have been kept hot to destroy germs, and stoppered with steril-

ized cotton, is effective, particularly if the bottles have a stopcock near the bottom to draw the infusion when wanted. Alméns has proposed a very efficient method of preserving infusions. (*A. J. P.*, April, 1875.) It is as follows: The infusion or decoction is heated for some time in a water bath at 100° C. (212° F.), and the bottle is then fitted with a tight cork, through which a glass tube passes lightly filled with cotton wool. The cork has a second opening, through which a glass tube passes nearly to the bottom of the bottle; this tube is bent at a sharp angle and has fitted to it a piece of india rubber tubing, to which a pinchcock is attached, by means of which the contents may be drawn as wanted. By making very concentrated infusions, as suggested by Donovan, with a mixture of three parts of water and one part of alcohol, they may be long kept, and when used can be diluted with water to the proper strength. Thus, if made four times as strong as the official infusion, they may be diluted with three measures of water. The proportion of alcohol would thus be very small, but it might still be medicinally injurious, and infusions should not be prepared in this way unless with the cognizance of the prescriber.

Battley, of London, introduced a set of preparations, which he called *inspissated infusions*, the advantages of which are that the virtues are extracted by cold water, are not injured by heat used in the evaporation, are in a concentrated state, and are not impaired by time. To prepare them he macerated the material, coarsely powdered, bruised, or finely sliced, in twice its weight of cold distilled water, pressing the solid matter into the liquid repeatedly by a rammer or the hand; then allowed the liquid to drain out, or expressed it in the case of highly absorbent substances, and repeated the process, with an amount of water equal to that which had been separated, until the strength was exhausted. Four or six hours of maceration were usually sufficient. The infusion is then to be concentrated by evaporation, at a temperature not exceeding 71.1° C. (160° F.) to the sp. gr. 1.200, and as much alcohol is to be added as will make its sp. gr. 1.100. These preparations are very analogous to the *fluidextracts* already considered. As a rule, it would probably be preferable to prepare infusions by the process of percolation.

The inspissated infusions must be diluted when administered. The presence of alcohol, though in small quantity, would sometimes be a serious objection. (*P. J.*, x, 129.) *Concentrated infusions* of the strength of 50 per cent. were introduced into the British Pharmacopœia (1898); they are mostly made by percolation, and were termed "Liquors." This certainly led to confusion in nomenclature, and it is difficult to understand why they were not called concentrated infusions, particularly as their almost universal use is for making ordinary infusions by diluting with water. They were dropped from the British Pharm. 1914.

INFUSUM ALSTONIÆ. Br.

INFUSION OF ALSTONIA

(ĭn-fū'sŭm ăl-stōn'ĭ-ą)

"Alstonia, bruised, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for half an hour; strain while hot." *Br.*

See *Alstonia*, page 119.

Dose, one-half to one fluidounce (15–30 mils).

INFUSUM AURANTII. Br.

INFUSION OF ORANGE PEEL

(ĭn-fū'sŭm âu-răn'tĭ-ī)

Tisane d'Ecorce d'Orange, *Fr.;* Pomeranzenschalenaufguss, *G.*

"Dried Bitter-Orange Peel, cut small, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

A grateful stomachic.

Dose, from one-half to one fluidounce (15–30 mils).

INFUSUM AURANTII COMPOSITUM. Br.

COMPOUND INFUSION OF ORANGE PEEL

(ĭn-fū'sŭm âu-răn'tĭ-ī cŏm-pŏs'ĭ-tŭm)

Tisane d'Ecorce d'Orange composée, *Fr.;* Pomeranzen und Citronenschalenaufguss, G.

"Dried Bitter-Orange Peel, cut small, 25 *grammes;* Lemon Peel, cut small, 10 *grammes;* Cloves, bruised, 5 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

A grateful stomachic in the *dose* of from one-half to one fluidounce (15–30 mils).

INFUSUM BUCHU. Br.

INFUSION OF BUCHU

(ĭn-fū'sŭm bū'ȼhū)

Infusum Diosmæ, s. Barosmæ; Tisane de Buchu, *Fr. Cod.;* Buchuaufguss, *G.*

"Buchu Leaves, freshly broken, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

It has the odor, taste, and medicinal virtues of the leaves, and affords a convenient method of administering the medicine.

Dose, from one to two fluidounces (30–60 mils).

INFUSUM CALUMBÆ. Br.

INFUSION OF CALUMBA

(ĭn-fū'sŭm cą-lŭm'bæ)

Infusion of Columbo; Tisane de Columbo, *Fr.;* Kolombo-Infusion, Kolomboaufguss, *G.;* Infusion de Colombo, *Sp.*

"Calumba Root, cut small, 50 *grammes;* Distilled Water, cold, 1000 *millilitres.* Infuse in a covered vessel for half an hour; strain." *Br.*

The *infusion of calumba* is likely to spoil very quickly, especially in warm weather. Ca-

lumba contains starch and albumen. Cold water extracts the latter without the former; hot water the former with comparatively little of the latter, which is partially coagulated by the heat. Both starch and albumen are liable to spontaneous change, but the former is much the more permanent of the two. Hence it is, according to Greenish, that the hot infusion keeps best. Indeed, he ascribes the change which takes place in the starch of the hot infusion chiefly to the agency of a little albumen which has escaped coagulation. According to these views, the best plan of preparing infusion of calumba is to exhaust the root with cold water, by which the starch is left behind, and then to heat the infusion to the boiling point in order to coagulate the albumen. (*A. J. P.*, xviii, 141; from *P. J.*) Upon comparing specimens of the cold and hot infusion, we have not found the results of Greenish fully confirmed. The cold infusion appeared to keep better than the hot. Nevertheless the plan of preparing the infusion above proposed is probably the best. The infusion of calumba is not colored by salts of iron, and may be conveniently administered in connection with them.

Dose, one fluidounce (30 mils), three or four times a day.

INFUSUM CARYOPHYLLI. Br.

INFUSION OF CLOVES

(ĭn-fū'zŭm căr-ŷ-o-phŷl'lī)

Tisane de Girofle, *Fr.;* Gewürznelken-Infusion, Gewürznelkenaufguss, *G.*

"Cloves, bruised, 25 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

The infusion of cloves affords precipitates with lime water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (Phillips.)

Dose, one fluidounce (30 mils).

INFUSUM CASCARILLÆ. Br.

INFUSION OF CASCARILLA

(ĭn-fū'zŭm căs-ca-rĭl'læ)

Tisane de Cascarille, *Fr.;* Kaskarillaufguss, *G.*

"Cascarilla, in No. 10 powder, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

This infusion affords precipitates with lime water, infusion of galls, silver nitrate, lead acetate and subacetate, zinc sulphate, and ferrous sulphate.

Dose, one fluidounce (30 mils).

INFUSUM CHIRATÆ. Br.

INFUSION OF CHIRETTA

(ĭn-fū'zŭm ch-rā'tæ)

Tisane de Chirette, *Fr.;* Chirettaufguss, *G.*

"Chiretta, cut small, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

Dose, from one-half to one fluidounce (15–30 mils).

INFUSUM CINCHONÆ ACIDUM. Br.

ACID INFUSION OF CINCHONA

(ĭn-fū'zŭm cĭn-ch-nō'næ ăc'ĭ-dŭm)

Infusion of Yellow Bark; Infusion of Calisaya Bark; Tisane de Quinquina jaune, *Fr.;* Kalisaya-Rindenaufguss, *G.*

"Red Cinchona Bark, in No. 40 powder, 50.0 *grammes;* Aromatic Sulphuric Acid, 12.5 *millilitres;* Distilled Water, boiling, 1000.0 *millilitres.* Mix the Red Cinchona Bark with the Distilled Water in a covered vessel; add the Aromatic Sulphuric Acid; infuse for one hour; strain while hot." *Br.*

Though the infusion with boiling water is more quickly prepared than the infusion with cold water, and therefore better adapted to cases of emergency, yet the former is a more elegant preparation, not turbid like the latter, and at least equally efficient. We therefore prefer the process of the U. S. Pharmacopœia, 1890, provided it be skilfully conducted. (See *U. S. Dispensatory,* 19th ed., p. 654.)

The U. S., 1890, infusion is an efficient preparation. Water extracts from bark quinine and cinchonine kinates, but leaves behind the compounds which these principles form with the cincho-tannic acid. The simple infusion, therefore, is rather feeble. But the addition of the acid insures the solution of all or nearly all the active matter. It would be best to macerate the bark with the acidulated water some time before it is introduced into the percolator. The infusion of cinchona, made without acid, affords precipitates with the alkalies, alkaline carbonates, and alkaline earths; the soluble salts of iron, zinc, and silver; corrosive mercuric chloride, arsenic trioxide, and tartar emetic; gelatinous solutions; and various vegetable infusions and decoctions, as those of galls, chamomile, calumba, cascarilla, horseradish, cloves, catechu, orange peel, digitalis, senna, rhubarb, valerian, and simaruba. In some instances the precipitate occurs immediately, in others not for several hours. The loss of few, however, of these substances by precipitation diminishes the efficacy of the infusion, as they do not affect the active principles. The alkalies, alkaline earths, and vegetable astringents are really incompatible. As gallic, tartaric, and oxalic acids form salts with quinine of somewhat difficult solubility, the neutral and soluble gallates, tartrates, and oxalates produce in the infusion slight precipitates of corresponding salts of the alkaloids, but these are redissolved by an excess of the acid. Antimony and potassium tartrate does not precipitate the alkaloids. Solutions of iodine are incompatible, forming with the alkaloids insoluble compounds. For an account of the chemical reactions of the infusions of different varieties of cinchona bark, see *A. J. P.*, ix, 128. The simple infusion of cin-

chona may be advantageously administered in cases which require tonic treatment but do not call for the full powers of the bark. The acid infusion has all the powers of cinchona itself.

Dose, one fluidounce (30 mils).

INFUSUM DIGITALIS. U. S., Br.

INFUSION OF DIGITALIS Inf. Digit.

(ĭn-fū'zŭm dĭg-ĭ-tā'lĭs)

Infusion of Foxglove; Tisane de Digitale, *Fr.;* Fingerhutaufguss, Digitalisaufguss, *G.;* Infusion de digital, *Sp.*

* "Digitalis, bruised, *fifteen grammes* [or 231 grains]; Cinnamon Water, *one hundred and fifty mils* [or 5 fluidounces, 35 minims]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Pour *five hundred mils* [or 16 fluidounces, 435 minims] of boiling water upon the digitalis, contained in a suitable vessel, and allow it to macerate for one hour. Then strain, add the cinnamon water to the strained liquid, and pass enough water through the residue on the strainer to make the product measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Mix well. *Infusion of Digitalis must be freshly prepared from the leaves."* *U. S.*

"Digitalis Leaves, in No. 20 powder, 7 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

This infusion is a valuable preparation and has been the subject of much discussion. The U. S. P. IX process has been improved by the deletion of alcohol, which was added for the purpose of preserving the infusion, which it did only partially. The present process, U. S. P. IX, is simple and satisfactory provided that great care is used in the selection of the digitalis.

The *infusion of digitalis* if prepared properly represents thoroughly the therapeutic activities of the drug. There is a belief among many clinicians that it is more actively diuretic than the tincture, but this idea is probably due to the fact that it is usually given in proportionately larger dose. According to Focke (*A. Pharm.,* ccxlix, p. 323) water will extract about 85 per cent. of the activity of digitalis leaves. As the infusion of digitalis deteriorates rapidly it is essential that it be freshly prepared for each order. It should also be made strictly according to the pharmacopœial process, the custom sometimes indulged in by careless pharmacists of diluting the fluidextract cannot be too severely condemned.

Dose of the U. S. infusion, one to four fluidrachms (3.75-15 mils). The British infusion is much weaker and may be given in doses of two to six fluidrachms (7.5–22.5 mils).

INFUSUM ERGOTÆ. Br.

INFUSION OF ERGOT

(ĭn-fū'zŭm ẹr'gọ-tæ)

Tisane de Seigle ergoté, *Fr.;* Mutterkornaufguss, *G.*

"Ergot, freshly crushed, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

Dose, two fluidounces (60 mils).

INFUSUM GENTIANÆ COMPOSITUM. Br.

COMPOUND INFUSION OF GENTIAN

(ĭn-fū'zŭm gĕn-tī-ā'næ cọm-pŏz'ĭ-tŭm)

Tisane de Gentiane composée, *Fr.;* Enzianaufguss, *G.*

"Gentian Root, thinly sliced, 12.5 *grammes;* Dried Bitter-Orange Peel, cut small, 12.5 grammes; Lemon Peel, cut small, 25.0 *grammes;* Distilled Water, boiling, 1000.0 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

The National Formulary IV introduced compound infusion of gentian which differs very slightly from that official in the U. S. P. 1870. (See *N. F.,* Part III.)

It has been the custom with some physicians to prescribe a concentrated infusion made with one-fourth the quantity of menstruum directed by the formula of U. S. P. 1870. This permits the use of a valuable tonic with the presence of but a trifling amount of alcohol. This concentrated preparation keeps well, and it may be diluted with the right quantity of the proper menstruum by the pharmacist to make the infusion of U. S. P. 1870. The use of the alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very prone to spoil. The alcohol has, however, been abandoned by the British Pharmacopœia, and lemon peel substituted.

Dose, one fluidounce (30 mils), repeated three or four times a day.

INFUSUM KRAMERIÆ. Br.

INFUSION OF KRAMERIA

(ĭn-fū'zŭm krą-mē'rĭ-æ)

Infusion of Rhatany; Tisane de Ratanhia, *Fr.;* Ratanhiawurzelaufguss, *G.*

"Krameria Root, bruised, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

The *infusion of rhatany* is undoubtedly most efficient when prepared from the root in a state of moderately coarse powder by the mode of percolation with cold water, as directed in the U. S. process of 1870.

Dose, of the infusion, from one to two fluidounces (30–60 mils).

INFUSUM QUASSIÆ. Br.

INFUSION OF QUASSIA

(ĭn-fū'zŭm quäs'sĭ-æ)

Tisane de Quassie, *Fr.;* Quassiaaufguss, *G.;* Infusion de cuasia amarga, *Sp.*

"Quassia Wood, rasped, 10 *grammes;* Distilled Water, cold, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain." *Br.*

Boiling water may be employed when it is desirable to obtain the preparation quickly, but

cold water affords a clearer infusion. The fifteen minutes maceration directed in the British Pharmacopœia, considering that cold water is used, appears to us to be too short for the exhaustion of the wood.

Dose, two fluidounces (60 mils), three or four times a day.

INFUSUM RHEI. Br.

INFUSION OF RHUBARB

(ĭn-fū'zŭm rhē'ī)

Tisane de Rhubarbe, *Fr.;* Rhabarberaufguss, *G.;* Infuso di rabarbaro, *It.;* Infusion de ruibarbo, *Sp.*

"Rhubarb, in thin slices, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

In order that the rhubarb may be exhausted, it should be digested with the water near the source of heat, at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamom, fennel seed, or nutmeg, which improves the taste of the infusion and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connection with the rhubarb.

This infusion may be given as a laxative, and is occasionally used as a vehicle for tonic, antacid, or more active cathartic medicines. The stronger acids and most metallic solutions are incompatible with it.

Dose, one to two fluidounces (30–60 mils).

INFUSUM ROSÆ ACIDUM. Br.

ACID INFUSION OF ROSES

(ĭn-fū'zŭm rō'zæ aç'ĭ-dŭm)

Infusum Rosæ Compositum, *N. F.;* Compound Infusion of Rose; Acid Infusion of Rose; Tisane de Rose composée, *Fr;* Saurer Rosenaufguss, *G.*

"Red-Rose Petals, dried and broken, 25.0 *grammes;* Diluted Sulphuric Acid, 12.5 *millilitres;* Distilled Water, boiling, 1000.0 *millilitres.* Add the Diluted Sulphuric Acid to the Distilled Water; infuse the Red-Rose Petals in the mixture in a covered vessel for fifteen minutes; strain while hot." *Br.*

The formula of the U. S. P. 1870 is preferable to that of the Br. Pharm. on account of the presence of sugar. It is unfortunate, in our opinion, that this elegant infusion was not reinstated at the last revision of the U. S. Pharmacopœia. We append the formula of the U. S. P. 1870: "Take of Red Rose [dried petals] *half a troyounce;* Diluted Sulphuric Acid *three fluidrachms;* Sugar [refined], in coarse powder, *a troyounce and a half;* Boiling Water *two pints and a half.* Pour the Water upon the Rose in a covered glass or porcelain vessel; add the Acid, and macerate for half an hour. Lastly, dissolve the Sugar in the liquid, and strain." *U. S.* The process for this infusion in the N. F. IV is practically the same. (See Part III.)

The red rose serves little other purpose than to impart a fine red color and a slight rose and astringent flavor to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. According to J. B. Barnes, one part of glycerin added to eight or nine parts of infusion of rose increases greatly its brightness and transparency. It is refrigerant and astringent, and affords a useful and not unpleasant drink in *hemorrhages* and *colliquative sweats.* It is much used by British practitioners as a vehicle for saline medicines, particularly magnesium sulphate, the taste of which it serves to cover. It is also employed as a gargle, usually in connection with acids, nitre, alum, or tincture of Cayenne pepper.

Dose, two fluidounces (60 mils).

INFUSUM SCOPARII. Br.

INFUSION OF BROOM

(ĭn-fū'zŭm scǫ-pā'rī-ī)

Tisane de Genêt à balais, *Fr.;* Besenginsteraufguss, *G.*

"Broom Tops, dried and bruised, 100 grammes; Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

This preparation has been introduced in place of the Decoction of Broom of the British Pharmacopœia of 1885. Water thoroughly extracts the virtues of broom, and the large quantity of water in each dose aids the diuretic action.

Dose, from one to two fluidounces (30–60 mils).

INFUSUM SENEGÆ. Br.

INFUSION OF SENEGA

(ĭn-fū'zŭm sĕn'ę-gæ)

Tisane de Polygale de Virginie, *Fr.;* Senegaaufguss, *G.*

"Senega Root, in No. 10 powder, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for half an hour; strain while hot." *Br.*

Dose, one fluidounce (30 mils).

INFUSUM SENNÆ. Br.

INFUSION OF SENNA

(ĭn-fū'zŭm sĕn'næ)

Senna Tea; Tisane de Séné, *Fr.;* Sennaaufguss, *G.*

"Senna Leaves, 100 *grammes;* Ginger, sliced, 5 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

We prefer the coriander of the U. S. P. 1870 to the ginger of the British. The infusion deposits, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency; it should, therefore, not be made in large quantities. It is customary to prescribe with it manna and some one of the saline cathartics, which increase its efficacy and render it less painful in its operation. (See *Infusum Sennæ Compositum.*) The cold infusion, especially if made by percolation from the coarsely powdered leaves, while probably not inferior in strength to that prepared with boil-

ing water, is said to be less unpleasant to the taste.

Dose, two fluidounces (60 mils).

Off. Prep.—Mistura Sennæ Composita, *Br.*

INFUSUM SENNÆ COMPOSITUM. U. S.

COMPOUND INFUSION OF SENNA Inf. Senn. Co.

(ĭn-fū'zŭm sĕn'næ cŏm-pŏz'ĭ-tŭm)

Tisane de Séné composée, *Fr.;* Infusum Sennæ Compositum, *P. G.;* Wiener Trank, Sennaaufguss, *G.;* Infuso di sena con manna, *It.*

* "Senna, *sixty grammes* [or 2 ounces av., 51 grains]; Manna, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Magnesium Sulphate, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Fennel, bruised, *twenty grammes* [or 309 grains]; Water, *a sufficient quantity,* to make *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. Pour *eight hundred mils* [or 27 fluidounces, 24 minims] of boiling water upon the senna, manna, and fennel contained in a suitable vessel, and allow the mixture to macerate for half an hour. Then strain, express and dissolve the magnesium sulphate in the Infusion, and again strain. Lastly, add enough water through the strainer to make the Infusion measure *one thousand mils* [or 33 fluidounces, 6½ fluidrachms]. This preparation must not be dispensed unless it has been recently prepared." *U. S.* (See *Mistura Sennæ Composita, Br.*)

This preparation is used in Europe and to some extent in this country. The synonym, "*Black Draught,*" has been deleted from the U. S. P. IX because of the similarity in name to "*Black Drop*" (Acetum Opii), death having resulted through the confusion in names. The taste is bitter and nauseous and the infusion is now rarely employed.

Dose, four fluidounces (120 mils).

INFUSUM UVÆ URSI. Br.

INFUSION OF BEARBERRY

(ĭn-fū'zŭm ū'væ ûr'sī)

Tisane d'Uva Ursi, *Fr.;* Bärentraubenblätteraufguss, *G.*

"Bearberry Leaves, bruised, 50 *grammes;* Distilled Water, boiling, 1000 *millilitres.* Infuse in a covered vessel for fifteen minutes; strain while hot." *Br.*

Dose, from one to two fluidounces (30–60 mils), three or four times a day.

INJECTIO APOMORPHINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF APOMORPHINE

(ĭn-jĕc'tĭ-ō ăp-ọ-mör-fĭn'næ hŷ-pọ-dẹr'mĭ-cą)

Injection hypodermique d'Apomorphine, *Fr.;* Subcutane Apomorphineinspritzung, *G.*

"Apomorphine Hydrochloride, 1 *gramme;* Diluted Hydrochloric Acid, 1 *millilitre;* Distilled Water, recently boiled and cooled, sufficient to produce 100 *millilitres.* Mix the Diluted Hydrochloric Acid with fifty millilitres of the Distilled Water; dissolve the Apomorphine Hydrochloride in the mixture, and add sufficient of the Distilled Water to produce the required volume. This Injection should be recently prepared. 100 millilitres contain 1 gramme of Apomorphine Hydrochloride; 110 minims contain 1 grain." *Br.*

Dose, by subcutaneous injection, from two to eight minims (0.12–0.5 mil).

INJECTIO COCAINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF COCAINE

(ĭn-jĕc'tĭ-ō cō-cą-ĭ'næ hŷ-pọ-dẹr'mĭ-cą)

Injection hypodermique de Cocaine, *Fr.;* Subcutane Cocaineinspritzung, *G.*

"Cocaine Hydrochloride, 5.00 *grammes;* Salicylic Acid, 0.15 *gramme;* Distilled Water, 100.0 *millilitres,* or *a sufficient quantity.* Boil the Distilled Water; add the Salicylic Acid; dissolve the Cocaine Hydrochloride in the solution when cool; add, if necessary, sufficient recently boiled and cooled Distilled Water to produce one hundred millilitres of the Injection. This Injection is of one-half the strength of the corresponding preparation of the British Pharmacopœia 1898. It contains 5 grammes of Cocaine Hydrochloride in 100 millilitres; 110 minims contain 5 grains." *Br.*

This injection is half the strength of Br. Pharm. (1898) preparation.

Dose, by subcutaneous injection, from two to ten minims (0.12–0.6 mil).

INJECTIO ERGOTÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF ERGOT

(ĭn-jĕc'tĭ-ō ẹr'gọ-tæ hŷ-pọ-dẹr'mĭ-cą)

Hypodermic Injection of Ergotin; Injection hypodermique d'Ergot de Seigle, *Fr.;* Subcutane Mutterkorneinspritzung, *G.*

"Extract of Ergot, 33 *grammes;* Phenol, 1 *gramme;* Distilled Water, recently boiled and cooled, sufficient to produce 100 *millilitres.* Dissolve. This Injection should be recently prepared. 100 millilitres contain 33 grammes of Extract of Ergot; 110 minims contain 33 grains." *Br.*

This preparation does not represent ergot. (See *Ergota,* page 428.)

Dose, by subcutaneous injection, from three to ten minims (0.2–0.6 mil).

INJECTIO MORPHINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF MORPHINE

(ĭn-jĕc'tĭ-ō mör-fĭn'næ hŷ-pọ-dẹr'mĭ-cą)

Injection hypodermique de Morphine, *Fr.;* Subcutane Morphinespritzung, *G.*

"Morphine Tartrate, 2.5 *grammes;* Distilled Water, recently boiled and cooled, sufficient to produce 100.0 *millilitres.* Dissolve. This Injection is of one-half the strength of the corresponding preparation of the British Pharmacopœia, 1898. It contains 2.5 grammes of Morphine Tartrate in 100 millilitres; 110 minims contain 2.5 grains." *Br.*

This solution is made from morphine tartrate in place of the morphine acetate formerly used; this is a great improvement, as the acetate is the most unstable of all morphine salts. The morphine strength of this injection is one-half that

of the Hypodermic Injection of Morphine of the British Pharmacopœia of 1898.

Dose, by subcutaneous injection, from five to ten minims (0.3–0.6 mil).

INJECTIO STRYCHNINÆ HYPODERMICA. Br.

HYPODERMIC INJECTION OF STRYCHNINE

(ĭn-jĕc'tĭ-ō strȳch-nī'næ hȳ-pō-dẹr'mĭ-cą)

"Strychnine Hydrochloride, 0.75 *gramme;* Distilled Water, recently boiled and cooled, sufficient to produce 100.0 *millilitres.* Dissolve. This Injection contains 0.75 gramme of Strychnine Hydrochloride in 100 millilitres; 110 minims contain ¾ grain." *Br.*

Dose, by subcutaneous injection, five to ten minims (0.3–0.6 mil).

INJECTIONES HYPODERMICÆ

HYPODERMIC INJECTIONS

(ĭn-jĕc-tĭ-ōnēs hȳ-pō-dẹr'mĭ-cæ)

Under this head are classed preparations which are recognized in the British Pharmacopœia for hypodermic application. These preparations are really of very little value, on account of their proneness to undergo decomposition, and the difficulty of maintaining their sterility, and are greatly inferior to the *hypodermic tablets* of various strengths which are now supplied by manufacturing pharmacists—the size of the tablets not varying with the strength, because it is always necessary to use so much diluent in order to make the tablet of sufficient size to handle conveniently. The tablets most used contain apomorphine, morphine, morphine and atropine, atropine, strychnine, pilocarpine, cocaine, hyoscyamine, physostigmine, hyoscine, nitroglycerin, or caffeine; each should be readily soluble in fifteen minims of water. These tablets should be made official, since their convenience, permanence, and accuracy in weight have caused them to come into universal use. The selection of the diluent is an important question; very finely powdered cane sugar has been employed, but is apt to produce local irritation and even abscesses. Sodium chloride has also been recommended, but the best diluent seems to be dried neutral sodium sulphate.

IODOFORMUM. U. S., Br.

IODOFORM Iodof.

(ī-ō-dọ-fôr'mŭm)

"Triiodomethane [$CHI_3 = 393.77$] usually obtained by the action of iodine upon alcohol or acetone, in the presence of an alkali or alkali carbonate. Preserve it in well-closed containers, in a cool place, protected from light." *U. S.*

"Iodoform, CHI_3, may be obtained by the action of iodine on ethylic alcohol in the presence of solution of potassium carbonate." *Br.*

Triiodomethane, Formyltriiodide; Iodoforme, *Fr. Cod.;* Iodure de formyle, *Fr.;* Iodoformium, *P. G.;* Jodoform, Carboneum jodatum, Trijodmethan, *G.;* Jodoformio, Trijodometano, *It.;* Yodoformo, *Sp.*

This compound, discovered by Sérullas about 1828, was later investigated chemically by J. B. Dumas. It was introduced as a remedy, about the year 1837, by R. M. Glover of London, and Bouchardat, of Paris, and was first adopted as official in the U. S. Pharmacopœia of 1870.

Preparation.—Cornélis and Gille published a process in *J. P. C.,* 1852, p. 196. (See *U. S. D.,* 14th ed., 511.) Other chemists have proposed processes, but they all depend upon the interaction of iodine, alcohol, or acetone in the presence of an alkali or alkaline carbonate. (See *U. S. D.,* 19th edition, p. 659.)

Iodoform is now made by electrolysis. An alkaline solution of sodium iodide is electrolyzed in the presence of alcohol, when, iodine being liberated at the anode, iodoform is obtained by the following reaction:

$$CH_3.CH_2OH + 10I + H_2O = CHI_3 + CO_2 + 7HI$$

The hydriodic acid formed combines with the sodium hydroxide present, to make sodium iodate, which, with the carbon dioxide, forms the side products. The temperature is kept at about 70° C. (158° F.) during the reaction and a diaphragm is used. The yield of iodoform is about 70 per cent. M. Otto produces iodoform industrially, direct from alkaline iodides, as follows: 100 kg. of water, 300 kg. of alcohol, 10 kg. of sodium carbonate and 55 kg. of potassium iodide are heated to 50° C. (122° F.) in a suitable vessel, and a current of ozone is passed through the mixture. Iodoform is deposited and crystallizes in a pure condition on the sides of the vessel and throughout the fluid itself. The alcohol may be replaced by acetaldehyde, acetone, etc. (*Ap. Ztg.,* 1900, 166.)

The fact, noticed by Lieben in 1870, that many other compounds besides ethyl alcohol yield iodoform when treated with iodine and alkali, led Krämer (*Ber. d. Chem. Ges.,* 1880, p. 1000) to propose the iodoform formation as an exact quantitative test for the presence of acetone in methyl alcohol. This "iodoform test" is now used in testing the purity of methyl alcohol for use in the manufacture of aniline dye colors, as well as the purity of acetone itself. It is also used as a confirmatory test for the identification of ethyl alcohol in the absence of acetone or aldehyde. (See *Acetonum.*) Heinrich Spindler proposes to make iodoform from the chlorides, bromides, or chloro-bromides of the paraffin series by reaction with an inorganic iodide; thus, if chloroform and *anhydrous* calcium iodide are heated to 120° C. (248° F.) iodoform is produced. (*Am. Drug.,* 1886, p. 67.) F. Günther recommends mixing alcohol containing 25 per cent. of aldehyde with ten times its weight of solution of sodium hydroxide, adding the iodine, and passing a current of carbon dioxide through the mixture. (*A. Pharm.,* 1887, p. 373.)

Properties.—It is in the form of "a fine, lemon-yellow powder, or in lustrous crystals of the hexagonal system, having a peculiar, very

penetrating and persistent odor, and an unpleasant, slightly sweetish taste suggestive of iodine. It is nearly insoluble in water to which it, however, imparts its odor and taste. One Gm. of Iodoform dissolves in 60 mils of alcohol, 80 mils of glycerin, 10 mils of chloroform, 7.5 mils of ether, 2.8 mils of carbon disulphide, and in 34 mils of olive oil at 25° C. (77° F.); also in about 16 mils of boiling alcohol. Its solutions are neutral to litmus.

Iodoform is slightly volatile, even at ordinary temperatures, and in boiling water distils slowly with the vapor of water. At about 115° C. (239° F.) it melts to a brown liquid, and at a higher temperature it decomposes, emitting vapors of iodine. Incinerate about 1 Gm. of Iodoform; not more than 0.2 per cent. of ash remains. Dry about 1 Gm. of Iodoform, accurately weighed, for twenty-four hours over sulphuric acid; the loss in weight does not exceed 1 per cent. Shake about 2 Gm. of Iodoform for one minute with 5 mils of distilled water and filter; the filtrate is colorless and free from bitter taste (*soluble yellow coloring matter, picric acid*), and does not affect the color of litmus (*acids or alkalies*)." *U. S.*

"Shining, lemon-yellow, small, hexagonal crystals, somewhat unctuous to the touch. Odor and taste persistent and disagreeable. Very slightly soluble in *water;* soluble in 100 parts of *alcohol* (90 per cent.), and in 8 parts of *ether,* the solutions being neutral to *litmus;* soluble also in *chloroform,* in *carbon disulphide,* in volatile oils, and in fixed oils; sparingly soluble in *benzene.* When warmed with *alcoholic solution of potassium hydroxide,* the resulting solution, acidified with *nitric acid,* becomes brown, and, when cold, changes to blue on the addition of *mucilage of starch.* 10 millilitres of *water* with which 1 gramme of Iodoform has been shaken are colorless and not bitter (absence of soluble yellow coloring matters and of picric acid), and yield no *reactions* for iodides. No appreciable ash." *Br.*

Iodoform is a volatile substance, soft to the touch, and totally devoid of corrosive properties. With potassium hydroxide in solution, it is decomposed, yielding potassium formate and iodide. Hence these two principles are incompatible in prescriptions. The specific gravity of iodoform, about which there has been a controversy, was determined by J. Percy Remington to be 4.000; the specific gravity of 2.000, as given in the U. S. P. 1890, was undoubtedly due to the operator taking the specific gravity of iodoform in water, and when this is done it is practically impossible to free the crystals from admixed air; the result was reached by using a saturated solution of iodoform in pure kerosene as the liquid, and by a simple calculation obtaining the equivalent in water. Iodoform is sometimes met with in commerce adulterated with water; Vulpius (*Ph. Cb.,* 1894) on examination detected 13 per cent. in one specimen.

Uses.—When applied locally, iodoform exercises a marked anesthetic action. Although of itself it is almost free of antibacterial properties, when brought in contact with the bodily secretions it gradually liberates some compound —perhaps free iodine—which is actively antiseptic. The experiments of Gosselin of Caen indicate that it is especially inimical to the tubercle bacillus. If taken internally it is gradually absorbed and is partially decomposed, liberating inorganic iodine; a part, however, appears to circulate unchanged. When exhibited in large doses, to the lower animals, it produces narcotic effects, and two stages in its operation have been noticed; the first is marked with more or less prostration, with symptoms of intoxication, the animal tottering, inclining to one side with the head falling, with loss of appetite, but without vomiting. The next day, unless a very large dose has been given, complete recovery takes place. A still larger dose induces the second stage, characterized by a remarkably intense excitation, with anxious breathing, strong and short pulse, a true opisthotonos, sometimes very striking, and convulsive movements of the paws, especially the hinder ones. After death fatty degeneration of the heart, liver, and kidneys may be found.

The chief value of iodoform in practical medicine is as an external application. It has long been used in cases of painful *ulcers* and as an antiseptic dressing to *wounds.* The testimony from surgeons is so strong that it is difficult to avoid believing that it is one of the most certain remedies of the class. Its beneficial effects seem to be due partly to absorption of secretions—making an unfavorable soil for bacterial growth—partly to the antiseptic effect of its decomposition products and partly to its local anesthetic effect. Some believe that it exerts some specific influence on cell growth that encourages healing. It is also of much value for its anesthetic powers in *laryngeal tuberculosis* and in *internal hemorrhoids;* in the latter condition it is best applied in the form of a suppository, which may contain from five to ten grains (0.3–0.6 Gm.).

The local application of iodoform in surgical *tuberculosis* has received the highest commendation from numerous surgeons. In the treatment of *tuberculous abscesses,* in tuberculous *empyema,* in *tubercular joints,* in non-suppurating *tuberculous glands,* and even in *tuberculous peritonitis,* numerous cures have been claimed. The manner of application varies with different surgeons. Verneuil, who has had an enormous experience, prefers in the treatment of abscesses and of tuberculous glands, and in most other cases, the injection of a 5 per cent. ether solution. Others prefer glycerin as a vehicle, especially in empyema cases, while others, especially in *peritonitis,* dust the dry powder over the surface which has been laid open.

Internally, iodoform has been used in *syphilis,*

goiter, and *phthisis,* originally with the idea that it would act as an iodide. As pointed out above, however, it is only partly broken up in the system and its action therefore is quite different from the inorganic iodides. Whether it is of any real value as internal remedy is at present open to doubt.

The very free use of iodoform in Germany as an antiseptic dressing to *wounds, ulcers,* etc., has led to many cases of poisoning. In the most characteristic and severe cases the phenomena of iodoform poisoning resemble somewhat those of meningitis; they are headache, somnolence, deepening into stupor, contracted, motionless pupils, abnormal quiet or restlessness ending in active delirium, with, however, a normal temperature and an exceedingly rapid pulse. Burlureaux affirms that if a piece of silver be placed in the mouth of a person suffering from iodoform poisoning, immediately the taste of garlic will be perceived, and if some of the saliva be mixed with calomel, a canary-yellow precipitate of mercurial iodide will be obtained. The most that such a test can accomplish is to show that the patient is under the influence of some compound of iodine. In cases of this character death almost always follows, although the symptoms may have developed abruptly and the dressing has at once been removed. In other cases the principal symptoms are general malaise and depression, faintness, headache, loss of appetite, and a persistent iodoform taste in the mouth. In some cases there is a slight temporary increase of temperature. Mental depression or excitement is especially noticed. Finally the pulse becomes accelerated, soft, and feeble; in some cases the pulse is very rapid—from 150 to 180—while the temperature remains normal or is only slightly elevated. It is asserted by Samter and Retzlaff (*T. G.,* 1889) that potassium bromide is an antidote in iodoform poisoning, its antidotal powers being due to the fact that it exceeds all other salts in its power of dissolving iodine compounds.

Langenstein has attributed a fatal result to the local application of one drachm of the powder. It is advisable that in ordinary cases not more than thirty grains (2 Gm.) be employed at once as a wound dressing, although in cases of tuberculosis the surgeon is warranted in taking the risk of larger amounts. Verneuil sometimes injects at one sitting 75 grains of the iodoform.

Iodoform gauze may be made by saturating surgical gauze with a 5 per cent. solution of iodoform in ether, and allowing it to dry at room temperature.

One of the principle obstacles to its employment is the odor, which, to some patients, is unbearable. Many methods of disguising the odor have been recommended, but in our experience the large quantity required of each deodorizing agent would preclude its employment. Tannin has been recommended, but, as this operates by decomposing the iodoform, it is not to be thought of in this connection. Probably the best class of substances to use are the volatile oils, such as anise, peppermint, fennel, bergamot, almond, etc., tonka, coffee, and balsam of Peru, although the latter acts by forming a compound, and the aim should be not to destroy the odor, but so to modify it as to remove its objectionable features. Olive oil saturated with camphor is said to dissolve 6 per cent. of iodoform, and is preferred by some surgeons.

Dose, one to five grains (0.065–0.32 Gm.).

IODUM. U. S., Br.

IODINE

(ī-ō′dŭm)

"It contains not less than 99.5 per cent. of I (126.92). Preserve it in glass-stoppered bottles, in a cool place." *U. S.* "Iodine may be obtained from the ashes of seaweeds and from native iodides and iodates. It contains not less than 99 per cent. of pure iodine, I." *Br.*

Iodinium, *U. S.* 1870; Iode sublimé, *Fr. Cod.;* Iode, *Fr.;* Jodum, *P. G.;* Jod, *G.;* Jodo, *It.;* Yodo, *Sp.*

Iodine is a non-metallic element, discovered in 1812 by Courtois, a soda manufacturer of Paris. It exists in certain marine vegetables, particularly the fuci or common sea weeds, which have long been its most abundant natural source. It has been reported in some fresh water plants, among which are the water cress, brooklime, and fine-leaved water hemlock; also in the ashes of tobacco, and of Honduras sarsaparilla. (Chatin.) It has been found in the beet-root of the grand duchy of Baden. (Lamy.) Macadam detected a trace of iodine in 100 gallons of water used for domestic purposes in Edinburgh, in several of the domestic animals, and in man. He detected it also in potatoes, beans, peas, wheat, barley and oats. (*P. J.,* Nov. 1854, p. 235.) It is doubtful whether iodine is as widely distributed in land plants as the above statements would indicate, and some allowance must be made for faulty methods used by earlier observers. Iodine has been reported to be present in the animal kingdom, as in the sponge, the oyster, various polypi, cod liver oil, and eggs, and, in the mineral kingdom, in sea water in minute quantity, in certain salt springs, as silver iodide in a rare Mexican mineral, in a zinc ore of Silesia, in native sodium nitrate, and in some kinds of rock salt. It is now obtained commercially from one of these sources—viz., from the native sodium nitrate, or Chili saltpetre, with which it occurs as sodium iodate. The production of the province of Tarapaca (Chili) has assumed large dimensions within recent years, as a result of higher prices established by a combination of Scotch, French,

and South American producers. The importations of iodine into the United States have increased greatly within the past two years, being 631,510 pounds in 1915 and 1,044,525 pounds in 1916 with a value of $2,447,764. Bussy has obtained iodine, in the proportion of one part in five thousand, from the coal gas liquor of the gas works of Paris. It was first discovered in the United States in the water of the Congress Spring, at Saratoga, by William Usher. It was detected in the Kanawha saline waters by Emmet, and it occurs in the bittern of the salt works of Western Pennsylvania, in the amount of about eight grains to the gallon. In sea weeds the iodine exists in the state probably of sodium iodide. In different countries sea weeds are burned for the sake of their ashes, the product being a dark-colored fused mass called *kelp*. This substance, besides sodium carbonate and iodide, contains more or less sodium chloride, potassium chloride, sodium sulphate, etc. The deep sea fuci contain the most iodine, and when these are burned at a low temperature for fuel, as is the case in the island of Guernsey, their ashes furnish more iodine than does ordinary kelp. (Graham.) According to Geo. Kemp, the laminarian species, especially *Laminaria digitata, L. saccharina,* and *L. bulbosa,* which are deep water sea weeds, and contain more potassium than sodium, are particularly rich in iodine.

Preparation.—Although most largely produced in South America, iodine is still obtained from kelp, and in Great Britain is manufactured chiefly at Glasgow. The kelp, which on an average contains 1-224th part of iodine, is lixiviated with water, in which about half dissolves. The solution is concentrated until a pellicle forms and allowed to cool, whereby nearly all the salts, except sodium iodide, are separated, they being less soluble than the iodide. The remaining liquor, which is dense and dark-colored, is made very sour by sulphuric acid, which causes the evolution of carbon dioxide, hydrogen sulphide and sulphurous acid, and the deposition of sulphur. The liquor is then introduced into a leaden still, and distilled with manganese dioxide into a series of glass receivers, inserted into one another, in which the iodine is condensed. In this process the sodium iodide is decomposed, and the iodine evolved according to the reaction:

$$2NaI + 2H_2SO_4 + MnO_2 = MnSO_4 + Na_2SO_4 + 2H_2O + I_2$$

which leaves as residue manganous sulphate and sodium sulphate. In this treatment much care is needed to avoid the liberation of chlorine from chlorides present, which will form volatile iodine trichloride and so occasion loss. This can be avoided by heating the acidified iodide solution with ferric chloride, when iodine is liberated according to the reaction:

$$2NaI + 2FeCl_3 = 2FeCl_2 + 2NaCl + I_2$$

The methods for the separation of the iodine from its combinations in the mother liquors as practised in South America may be divided essentially into three classes. (1) The mother liquors after the crystallization of the saltpetre without further concentration are treated with a solution of sodium sulphite of strength exactly corresponding to the amount of iodine present, for if an excess be used the iodine will be converted into hydriodic acid; the iodine is liberated according to the reaction:

$$2NaIO_3 + 4HNaSO_3 + SO_2 = Na_2SO_4 + 4HNaSO_4 + I_2$$

the iodine thus separated from the sodium iodate is filtered through linen cloth, washed, pressed, and sublimed. (2) The mother liquors are treated with sodium sulphite or bisulphite until the precipitated iodine is converted into HI, and this is precipitated as cuprous iodide by a solution of copper sulphate and sodium sulphite. (3) The amount of iodine is increased by fractional evaporation and crystallization of the mother liquors, and then, after adding the calculated amount of sodium bisulphite, the iodine is distilled off from the acidified liquor.

The methods formerly practised for obtaining iodine from sea weeds were accompanied with great loss. A notable improvement over the old kelp processes are the "char" and "wet" processes of E. C. C. Stanford (*J. Soc. Chem. Ind.*, 1885, p. 518), which show the following results when compared with the old processes. *Kelp process;* per cent. utilized, 18; kelp, 18 tons, yield salts 9 tons and iodine 270 lbs.; residues, kelp waste 18 tons, valueless. *Char process;* per cent. utilized, 36; char, 36 tons, yield salts 15 tons and iodine 600 lbs.; residues, charcoal 36 tons, tar, and ammonia. *Wet process;* per cent. utilized, 70; water extract, 33 tons, yield salts 20 tons and iodine 600 lbs.; residues, algin 20 tons, cellulose 15 tons, dextrin, etc.

Still another improvement was made in Germany (A. James, German Patent No. 95,063, of March 17, 1897), whereby over 91 per cent. of the iodine present in the sea weed has been recovered. Sea weed either wet or dry is immersed in sea water that has previously been treated with quicklime to precipitate the magnesia and give a distinctly alkaline reaction. The sea weed in the proportion of about one ton to the cubic meter of water is left immersed for twelve hours, during which time about 60 per cent. of the iodine is dissolved. It is then leached for six hours, each time in a second and third portion of prepared sea water. The combined extraction waters are then treated with ferrous sulphate, to coagulate mucilaginous matter, neutralized with sulphuric or hydrochloric acid, and the iodine then set free with an oxidizing agent like nitric acid or persulphate of ammonium, 1.5 kilos of nitric acid being required per cubic meter of solution. Iodine thus freed is extracted with petroleum naphtha, this solution being agitated with caustic alkali to form iodide and iodate, which are then treated in the usual manner.

Iodine is purified by sublimation in containers of porcelain, earthenware or glass, taking care to reject any white crystals which may appear in the first portion which comes over, which consists of cyanogen iodide. Moisture which has sometimes been reported to the extent of 15 or 20 per cent. and which may be suspected if the iodine adheres to the inside of the container in which it is kept, may be readily detected by assaying for the iodine content and also by the fact that such iodine will not make a transparent solution with chloroform.

Properties.—Iodine is described by the U. S. Pharmacopœia as "heavy, bluish-black, brittle, rhombic plates, having a metallic luster, a distinctive odor, and a sharp and acrid taste. Specific gravity: about 4.66 at 17° C. (62.6° F.). Iodine imparts a deep brown, evanescent stain to the skin, and slowly destroys vegetable colors. One Gm. of Iodine dissolves in 2950 mils of water, 12.5 mils of alcohol, 80 mils of glycerin, and in 4 mils of carbon disulphide at 25° C. (77° F.); freely soluble in chloroform, ether, or aqueous solutions of iodides; its solution in alcohol or in an aqueous solution of potassium iodide has a reddish-brown color; its diluted solution in chloroform or carbon disulphide has a violet color. Iodine volatilizes slowly at ordinary temperatures. When heated to about 114° C. (237.2° F.) it fuses and is gradually dissipated in the form of a purple vapor, leaving not more than 0.05 per cent. of residue. Add starch T.S. to a saturated aqueous solution of Iodine; a blue color is produced. On boiling the mixture the color is discharged but reappears as it cools, unless it has been subjected to long continued boiling. A solution of Iodine in chloroform is transparent (*moisture*). To determine the presence of cyanogen, chlorine or bromine, proceed as follows: Triturate 0.5 Gm. of finely powdered Iodine with 20 mils of distilled water and filter the solution. To one-half of the filtrate carefully add tenth-normal sodium thiosulphate V.S. until the solution is just decolorized. Then add a few drops of ferrous sulphate T.S., and subsequently a little sodium hydroxide T.S., and heat the mixture gently. On now adding a slight excess of hydrochloric acid, the liquid does not become blue (*cyanogen iodide*). To the other half of the aqueous filtrate, in a test tube, add a slight excess of silver nitrate T.S., shake the liquid actively, allow the precipitate to subside, and, having poured off the clear, supernatant liquid completely, shake the precipitate with a mixture of 1 mil of ammonia water and 9 mils of distilled water, and filter. On adding a slight excess of nitric acid to the filtrate, not more than a slight opalescence makes its appearance (*chlorine or bromine*).

"**Assay.**—Introduce about 0.5 Gm. of powdered Iodine into a tared weighing-bottle, stopper, weigh accurately, and add 1 Gm. of potassium iodide dissolved in 5 mils of distilled water. Dilute this solution with distilled water to about 50 mils and titrate with tenth-normal sodium thiosulphate V.S., starch T.S. being used as indicator. It shows not less than 99.5 per cent. of I.

"Each mil of tenth-normal sodium thiosulphate V.S. used corresponds to 0.012692 Gm. of I. Each gramme of Iodine corresponds to not less than 78.4 mils of tenth-normal sodium thiosulphate V.S." *U. S.*

"In rhombic prisms or octahedrons of the trimetric system, of dark color, and metallic lustre. Characteristic odor. Yields, when gently heated, a violet-colored vapor. Very slightly soluble in *water,* more soluble in *alcohol* (90 per cent.); readily soluble in *solution of potassium iodide,* in *ether,* and in *carbon disulphide. Mucilage of starch* colors the aqueous solution deep blue. Sublimes without appreciable residue, the first portion sublimed not including any slender colorless prisms emitting a pungent odor (absence of iodine cyanide). A solution of Iodine in *chloroform* is perfectly clear (absence of moisture). 0.5 gramme, dissolved in 50 millilitres of *water* containing 1 gramme of *potassium iodide,* requires for decolorisation not less than 39 millilitres of *N/10 solution of sodium thiosulphate.*" *Br.*

It is a volatile substance, and evaporates even at common temperatures. Its vapor has the sp. gr. 8.7, being the heaviest gaseous substance known. If inhaled mixed with air, it excites cough and irritates the nostrils. When it comes in contact with cool surfaces, it condenses in brilliant steel-gray crystals. Iodine is freely soluble in alcohol and ether, but requires 3000 times its weight of water to dissolve it. If water stands on iodine for some time, especially in a strong light, it apparently dissolves more iodine, but the result depends upon the formation of hydriodic acid, in a solution of which iodine is more soluble than in water. The solution of iodine in water has a slight disagreeable taste, a feeble odor, and a light-brown color; its solution in alcohol or ether is nearly black. Its solubility in water is very much increased by the addition of certain salts, as sodium chloride, ammonium nitrate, or potassium iodide, and the same effect is produced, to some extent, by tannic acid. Its solution in tannic acid is called *iodo-tannin,* of which Socquet and Guillermond made a syrup for internal and an aqueous solution for external use. It is also soluble in glycerin, as ascertained by Cap in 1854. According to I. Walz, glacial acetic acid is an excellent solvent of iodine, at least equal to alcohol. When the acid is heated to boiling with excess of iodine, and then allowed to cool slowly, it deposits iodine in beautiful large slender crystals, sometimes half an inch long, much larger and more abundant than those formed from other solutions. (*Chem. News,* 1873, p. 233.) In chemical characters iodine resembles chlorine, but its affinities are weaker. It combines with most of the non-metallic and nearly all the metallic elements, forming a class of compounds called iodides. Some of these are official, as the iron, mercury, lead, potassium, sodium, strontium, and sulphur iodides. It

forms with oxygen one oxide, *iodic oxide*, I_2O_5, and two acids, *iodic* and *periodic*, and with hydrogen an acid called *hydriodic acid* which is official as the diluted acid and in the syrup.

Tests.—Iodine, in most cases, may be recognized by its characteristic purple vapor; but, where this cannot be made evident it is detected unerringly by starch, which produces with it a deep-blue color. The test was discovered by Colin and Gaultier de Claubry, and is so delicate that it will indicate the presence of iodine in 450,000 times its weight of water. In order that the test may succeed, the iodine must be free, and the solutions cold. To render it free when in combination, as it always is in the animal fluids, a little chlorine, free from iodine, must be added to the solution suspected to contain it. Thus, in testing urine for iodine, the secretion is mixed with starch, and acidulated with hydrochloric acid and a drop or two of chlorine water added, when, if iodine be present, the color produced will vary from a light purple to a deep indigo blue, according to the amount of the element present. Sometimes in mineral waters the proportion of iodine is so minute that the starch test, in connection with chlorine, gives a doubtful coloration. In such cases a large volume of the water, sometimes as much as 10 liters, must be evaporated to dryness and the residue extracted with a minimum amount of water and the tests applied to the solution thus obtained.

Bargu and Starling (*P. J.*, 1914, xcii, 146) have called attention to the fact that other organic compounds besides starch have the property of showing a blue color with iodine, and have published a list of more than sixty such substances.

The detection and estimation of iodine in small amounts in combinations containing organic matter may be accomplished by methods analogous to the one used for the estimation of iodine in thyroid glands, which see.

One of the most delicate reactions yet devised for the qualitative detection of iodine is that recently discovered by Ciusa and Terni (*Gaz. Ch. It.*, 43, ii, 86) in which a solution composed of 10 grammes of mercuric nitrate, 50 mils of distilled water, 5 mils of nitric acid, and 60 mils of stronger ammonia water, is used. One mil of the reagent is added to 25 mils of the solution to be tested, chlorides give a white precipitate and bromides a yellow precipitate, neither of which are distinctive or interfere in any way. If iodides are present even in minute amounts a yellowish-red or brownish-red color or precipitate is produced.

It has been long known that when a mixture of iodine and starch in water is subjected to heat the blue color disappears, and that, if the heat be not too long continued, so as to volatilize the iodine or convert it into hydriodic acid, the color will return on the cooling of the liquid. Various explanations have been given of this curious fact by Personne and others, but the only one that is quite satisfactory is that by Magnes-Lahens, which he supports by experiment, that during the continuance of the heat the particles of starch and iodine separate, to unite again on refrigeration. (*J. P. C.*, 4e sér., iii, 405.)

Adulterations.—Iodine is said to be occasionally adulterated with mineral coal, charcoal, plumbago, and black manganese oxide. These are easily detected by their fixed nature, while pure iodine is wholly volatilized by heat. Herberger found native antimony sulphide in one sample, and plumbago in another, and Righini has detected as much as 25 per cent. of calcium chloride. The presence of cyanogen iodide and of water has already been referred to, and the modes of detecting and separating them pointed out. (See page 590.) Besides this test the British Pharmacopœia directs that the official iodine should be soluble in alcohol, ether, and a solution of potassium iodide, and should sublime without residue, and that the part which first comes over should contain no colorless prisms of a pungent odor.

Uses.—Iodine was first employed as a medicine in 1819, by Coindet, of Geneva. Iodine, whether taken into the stomach in the form of the element or as one of the salts of hydriodic acid, is absorbed readily and circulates in the blood chiefly in the form of an iodide, although it is probable that a small amount of the iodine is absorbed in the form of a protein compound. Although it can be found in a number of other secretions it is eliminated practically entirely through the kidneys. Elemental iodine is also capable of being absorbed through the skin; Herzfeld and Elin (*B. M. J.*, October 5, 1912) have shown that iodine can be demonstrated in the urine after painting the skin with the tincture. As iodine circulates as an iodide the effects are the same whether it be given in the elemental state or as a salt of hydriodic acid. Although Macht (*J. H. B.*, 1914, xxv) states that the iodine ion is a powerful stimulant when perfused through isolated heart or blood vessels, when introduced into the circulation of the intact mammal it has practically no influence. The common belief that the iodides dilate the arterioles is absolutely without reasonable foundation. The only important physiological effect of iodide is its influence upon metabolism. This action is not clearly understood although it is evident that the continued use of this drug increases the rapidity of nitrogenous breakdown; according to Chistoni (*A. I. P. T.*, xxi, p. 339), the elimination of uric acid and other purin bases is increased disproportionately. It appears to have some influence upon glands—beyond its action as a salt—not only increasing the quantity but changing the character of their secretions, especially diminishing excessive viscidity. In those morbid states attended with fibrinous exudation, the iodides have a similar effect on the exudate. There is a belief among many practitioners that it will even cause the absorption of organized fibroid tissue; this, however, is not well substantiated. In *syphilis* and *tuberculosis* there is often a very rapid breaking

down of the characteristic local lesions. This effect seems to be due to an increased autolysis but whether a specific reaction in certain diseases or merely the manifestations of general effect in the *locum minoris resistentiæ* is uncertain.

In *syphilis* iodine is without a direct curative property, that is, it has no effect upon the growth of the specific micro-organism. Because, however, of its power of causing the breakdown of syphilitic lesions it is a remedy of utmost importance in the tertiary stage, not merely because it lessens the extent of the sequelæ of the luetic affection, but because it drives the spirochetes from their lurking places into the general circulation where they may be reached by direct antisyphilitics. In the early stages iodine is useful because it forms a freely soluble compound with the mercury and thereby tends to prevent the deposit of the metal in internal organs.

Its effect in tuberculosis is analogous to that in *syphilis,* but whether this action in hastening the breakdown of the lesions will be beneficial or otherwise to the tuberculous patient, depends upon the location and character of the infection. Thus in *phthisis* generally the most favorable result is the walling off and ultimate calcification of the local lesion and the iodides by softening the infected area may not only delay the whole process, but may even cause a dissemination of themicro-organisms throughout the lung. On the other hand, in inoperable *lymphadenitis* it will hasten suppuration and may lead to the extrusion of the bacilli. In a somewhat similar way iodine may be useful in *bony tuberculosis.* In *leprosy* it apparently has a somewhat similar type of action, although less marked. It has also a potent effect in *actinomycosis* and even appears to have a direct curative effect. In inflammations of either the serous or mucous membranes attended with fibrinous exudates or viscid secretions, as *pleurisy, pericarditis,* or *bronchitis,* iodine is often of great value because of its liquefying action. In *bronchitic asthma,* while it has no direct influence upon the paroxysms, by its effect in increasing and liquefying the bronchial secretions it proves itself one of the most frequently serviceable drugs we possess. In chronic inflammatory conditions accompanied with a formation of fibroid connective tissue, as in *interstitial nephritis, arteriosclerosis,* and fibroid degenerations of the nervous centers, it is widely employed, not, however, because it is of proven utility but in a kind of despairing hope that it may produce some amelioration of the condition. In degenerative changes occurring as the result of *syphilis,* however, such as *locomotor ataxia,* it often appears to have some beneficial effect. It is habitually employed in *chronic rheumatism* which it probably influences through its action upon metabolism. The experiments of Reid Hunt (*J. P. Ex. T.,* 1910, ii, 15) indicate that iodine is a stimulant to the thyroid gland, which may explain its beneficial influence in simple *goiter* and its harmful effects in exophthalmic goiter. Potassium iodide forms in the body a freely soluble compound with either mercury or lead, and is therefore frequently used in the treatment of *lead poisoning* or in *mercurial* cachexia to hasten the elimination of the metal; it must be remembered, however, that by causing the solution of deposits it may cause an exacerbation of symptoms.

Elemental iodine has two important therapeutic properties which its salts do not share. These are as a local irritant and as a germicide. As a counter-irritant it is used especially in various forms of *arthritis,* notably those due to trauma, but is also of service in *bronchitis* or *glandular enlargement.* Its action in these conditions may be aided by absorption through the skin and consequent systemic effects of the drug. It is also employed for its local irritant effect as an injection for the cure of local effusions, as *ovarian dropsy, hydrocele,* and *ganglion.*

Antiseptic Uses.—Elemental iodine is a powerful germicide. Goebel (*Cb. B.,* 1906, xlii, p. 86) finds that a 1 to 1000 solution killed the *Staphylococci* after one minute's exposure and even the highly resistant anthrax spores if the exposure was prolonged to 15 minutes; Hailer found that as little as 1 part in 8000 was sufficient to destroy the staphylococci in 2 minutes. According to Peck (*P. J.,* 1911, lxxxvii, p. 450), a 1 to 1000 aqueous solution of iodine will kill the typhoid bacillus in one minute, but 1 in 10,000 will not kill it in three minutes. Of great importance in the practical use of iodine in surgery is its power of penetrating the skin. Turner and Catto (*L. L.,* 1911) found that after the external application of a 3 per cent. solution of iodine the whole thickness of the skin was sterile. Bovee (*Am. J. Obstetrics,* July, 1911) found that the application of 5 per cent. of the U. S. P. tincture of iodine completely sterilized the surface of the skin within 15 minutes but that hairy regions, as the pubes, required 50 per cent. of this tincture (representing 3 per cent. of iodine) for complete sterilization.

In 1908 Grossich (*Cb. Chir.,* 1908, p. 1285) suggested painting of the skin with a 10 per cent. tincture of iodine as a means of sterilizing the site of operation. According to his claims no previous washing was necessary because of the penetrating power of the iodine. The method has been widely followed and with more or less modification is now almost universally employed by surgeons. Probably the most commonly employed routine in this country is to cleanse the skin with liniment of soft soap, thoroughly wash away the soap with alcohol, and then paint with the official tincture of iodine. Among the various solutions which have been suggested instead of the tincture, probably the most widely employed is that in benzin originally suggested by Heussner. This author used a solution containing one part of iodine, 750 of benzin, and 250 of liquid petro-

latum. Reich-Brutzkus (*W. K. W.*, 1913) uses a solution containing 3 parts of iodine, 10 parts of alcohol, and 90 of chloroform. From its use in sterilizing the seat of operation iodine has rapidly come into popularity as a surgical disinfectant for a wide variety of purposes. Woodbury (*N. Y. M. J.*, 1912, xcvi, p. 101) recommends it to sterilize the surgeon's hands, instruments, sutures, and dressings. Painting recent wounds with tincture of iodine, it is asserted, is an efficient protection against infection by most of the common pus producing organisms. Magi (*Policlinico*, xxii, 517) highly recommends in *erysipelas* painting the affected part with tincture of iodine. In proper dilutions it is used in various infections of mucous membranes as *conjunctivitis, urethritis, diphtheria, cystitis*, etc. More recently the vapors of nascent iodine have been employed in various local infections. These may be generated by heating iodoform. It is also used locally in various skin diseases both for its antiseptic and alterative effect.

Lugol used aqueous solutions of iodine in which the element is dissolved by double its weight of potassium iodide. These solutions were of varying strength according to the purpose for which they were employed. His *iodine lotion*, used as a wash in scrofulous *ophthalmia*, in *ozena*, etc., contained two grains of iodine and four of potassium iodide in a pint of water. His *rubefacient iodine solution* is formed by dissolving half an ounce of iodine and an ounce of potassium iodide in six fluidounces of water. *Lugol's caustic iodine solution* is made of iodine and potassium iodide, each, an ounce, dissolved in two fluidounces of water. This is used to destroy soft and fungous granulations, and has been employed with decided benefit in *lupus*. Under the name of *iodine paint* an alcoholic solution similar to the official tincture, but of twice the strength, is employed.

A mode of applying iodine locally has been suggested by R. Greenhalgh, of London, which consists in thoroughly impregnating raw cotton with a solution in glycerin of potassium iodide and of iodine, in the proportion of two ounces of the former and one ounce of the latter to eight ounces of the menstruum, and then drying the "*iodized cotton.*" It is intended for application to the cervix or os uteri, which is effected through a speculum. (*L. L.*, May 26, 1866, p. 582.) Méhu's method of making iodized cotton is as follows: Finely divided iodine (5 to 10 parts) is sprinkled between layers of loose cotton (100 parts) introduced into a tall glass vessel, and the latter placed horizontally on a water or sand bath. As soon as vapors of iodine are seen to rise, and the air has been expelled from the vessel, the latter is tightly stoppered. On continuing to apply a moderate and uniform heat, the iodine vapors penetrate the cotton, and color it yellow. After about two hours, the cotton will have assumed the color of burnt coffee, and the operation is finished. Cotton iodized in other ways, as by immersion in concentrated solutions of iodine in ether or carbon disulphide, retains merely traces of iodine. (*N. R.*, April, 1867.)

Iodine, in the state of vapor, has been employed by inhalation, in the treatment of *phthisis* and *chronic bronchitis*, but has failed to fulfil expectations, and is at present very rarely practised. For details as to methods, the reader is referred to the 14th edition of the *U. S. D.*

Under the names of *iodagol* and *iodéol* suspensions asserted to contain 25 per cent. and 20 per cent., respectively, of *colloidal iodine* have been introduced for local applications.

As an internal remedy one of the salts of hydriodic acid is usually preferred as being less prone to disturb digestion although the compound solution is frequently of service. (See page 646.) For endermic absorption the ointment of iodine is the most useful of the official preparations. Although less irritant than iodine the alkaline iodides are still very prone to upset the stomach. This fact has led to the recommendation of a host of compounds and preparations, many of which are noticed in Part II of this work.

In an overdose iodine acts as an irritant poison. From four to six grains (0.26–0.4 Gm.), in man, cause a sense of constriction in the throat, sickness and pain at the stomach, and at length vomiting and colic. Even in medicinal doses it sometimes causes alarming symptoms, such as fever, restlessness, disturbed sleep, palpitations, excessive thirst, acute pain in the stomach, vomiting and purging, violent cramps, frequent pulse, and, finally, progressive emaciation if the medicine be not laid aside. Such violent symptoms are, however, very rare, but where iodine or potassium iodide is given freely a mild *iodism* is not unfrequent. It is usually characterized by pain or heaviness in the region of the frontal sinuses, with or without coryza; in some instances soreness of the mucous membrane of the mouth and throat, or a mild ptyalism, is the prominent symptom, or a papular eruption may be the first manifestation of the constitutional action of the remedy. Absorption of the mammæ and wasting of the testicles have been reported as caused by the long-continued use of the drug, but such results are extremely rare.

In cases of poisoning by iodine, the stomach must be evacuated, and drinks administered containing an amylaceous substance, such as flour, starch, or arrow-root.

Dose, of iodine, one-twelfth to one grain (0.005–0.065 Gm.) well diluted.

IPECACUANHA. U. S. (Br.)

IPECAC Ipecac. [Ipecacuanhæ radix P. I.]

(ĭp-ẹ-căc-ŭ-ăn'hạ)

"The dried root of *Cephaelis Ipecacuanha* (Brotero) A. Richard, known in commerce as Rio Ipecac, or of *Cephaelis acuminata* Karsten, known in commerce as Cartagena Ipecac (Fam. *Rubiaceæ*), without the presence or admixture of more than 5 per cent. of stems or other foreign matter and yielding not less than 1.75 per cent. of the ether-soluble alkaloids of Ipecac." *U. S.* "Ipecacuanha Root is the dried root of Psychotria Ipecacuanha, *Stokes*." *Br.*

Ipecacuanhæ Radix, *Br.*, Ipecacuanha Root; Poaya, *Braz.* Ipécacuanha annelé ou officinale, *Fr. Cod.*; Racine brésilienne, *Fr.*; Radix Ipecacuanhæ, *P. G.*; Ruhrwurzel, Brechwurzel, Ipecacuanha, *G.*; Ipecacuana, *It.*; Ipecacuana (Raiz de), *Sp.*

The term *ipecacuanha,* derived from the language of the aborigines of Brazil, has been applied to various emetic roots of South American origin. The botanical character of the ipecac plant of commerce was long unknown. At the present time the plant is well known, but there is considerable conflict regarding the proper botanical name to designate it. The several Pharmacopœias differ from each other in the generic names used, and hence there may be some confusion. The U. S. Pharmacopœia wisely retains the generic name *Cephælis,* this having been recognized for years in this country. The British Pharmacopœia uses the generic name *Psychotria,* which practice has been followed in that country for many years. The Swiss and German Pharmacopœias follow Engler and Prantl, and use the generic name *Uragoga.* The latter is probably correct, but in view of the unstability of this subject, particularly as other generic names have been proposed and may even supersede all of these it is wise to adhere to the old name *Cephælis,* thus causing no confusion.

Cephaëlis Ipecacuanha is a small shrubby plant, with a slender root from four to six inches long, marked with annular rugæ, simple or somewhat branched, descending obliquely into the ground, and here and there sending forth slender fibrils. The stem is two or three feet long, but, being partly under ground, and often procumbent at the base, usually rises less than a foot in height. It is slender; in the lower portion leafless, smooth, brown or ash-colored, and knotted, with radicles frequently proceeding from the nodes; near the summit, pubescent, green, and furnished with leaves seldom exceeding six in number. These are opposite, petiolate, oblong-obovate, acute, entire, from three to four inches long, from one to two broad, obscurely green and somewhat rough on their upper surface, pale, downy, and veined on the under. At the insertion of each pair of leaves are deciduous stipules, embracing the stem, membranous at the base, and separated above into numerous bristle-like divisions. The flowers are small, white, each accompanied with a green bract, and collected in a semi-globular head, supported upon a round, solitary, axillary footstalk, and embraced by a monophyllous involucre. The latter being deeply divided into four, sometimes five or six, obovate, pointed segments. The fruit is an ovate, obtuse berry, which is at first purple, but becomes almost black when ripe, and contains two small plano-convex seeds.

Cephaëlis tomentosa, of Trinidad, has been studied by Francis Ransom, who finds that it contains emetine, but in too small quantity for commercial purposes. For description of the root, etc., see *P. J.*, xix, p. 258.

The Rio ipecac plant of Brazil flourishes in moist, thick, and shady woods, being most abundant within the limits of the eighth and twenty-second degrees of south latitude. It flowers in January and February, and ripens its fruit in May. The root is active in all seasons, but, as it has to be dried rapidly, collection during the rainy season is relaxed. The native collector, or *poayero,* seizes all the stems of a clump, loosens them by a zigzag motion, and then, thrusting a pointed stick under the roots, tears up the whole mass. The roots, freed from dirt by shaking, are then dried. The amount gathered daily varies from 8 to 30 pounds, according to skill and locality. Extirpation does not take place, because, as shown by the Edinburgh gardeners McNab and Lindsay, a very small fragment of the root, or even a petiole of a leaf, will rapidly produce a new plant. Weddell, indeed, many years since, stated that the remains of the root, often purposely left in the ground, serve the purpose of propagation, each fragment giving rise to a new plant. Ipecac of commerce comes chiefly from the interior province of Matto-Grosso, upon the upper waters of the Paraguay (from which in some years as much as 450,000 kilos are shipped), although some is said to be gathered near Philadelphia north of Rio Janeiro. The chief places of export are Rio Janeiro, Bahia, and Pernambuco. It is brought to the United States in large bags or bales. The importation into the United States have increased from 78,654 pounds in 1914 to 203,734 pounds in 1916.

Unofficial Varieties of Ipecac.—From time to time there have been imported into Europe various drugs stated to be ipecac, but differing from the official drug. Of these the most important are White Ipecac; the Larger Striated Ipecac of Planchon (*J. P. C.*, Déc., 1872); and the Lesser Striated Ipecac of Planchon.

Larger Striated Ipecac (Planchon). *Violet Striated Ipecac. Ipecac of St. Martha. Ipecac of Carthagena. Striated Elastic Ipecac* (Attfield).—This variety of ipecac is generally acknowledged to be the product of *Psychotria emetica* L., growing in the deep forests of Colombia. The drug occurs in rather long fragments, sometimes 9 or 10 cm., with a thickness of from 5 to 9 mm. The pieces are for the most part almost straight, sometimes sinuous, more rarely tortuous. At distant intervals they are marked by contractions, or circular fur-

rows. Their whole surface is largely striated longitudinally. To their upper part are often attached one or more remaining portions of the stem, distinguished from the root by their much smoother surface. Their color is a grayish-brown, tending sometimes to reddish-brown. Like other ipecacs, they have an outer cortical and a central ligneous portion. The former is soft, so that it may even be penetrated by the nail. It has a horny aspect, and a variable color, passing from whitish, by shades of rose, violaceous, and blackish violet. Its thickness is at least two-thirds of the root, and becomes still greater when this is immersed in water. The central part is yellowish-white. The root has little odor, and a taste scarcely nauseous, sometimes flat, and often sweetish. As to the microscopic characters, the most striking are probably the total absence of the starch granules, and the relatively very small diameter of the vessels in the central part. Chemically this variety is characterized by the presence of sugar. It also contains 0.027 per cent. of emetine.

Lesser Striated Ipecac (Planchon). *Ipecac des Côtes d'Or* (Pelletier). *Black Ipecac. Black Striated Ipecac. Striated Brittle Ipecac* (Attfield). *False Ipecac* (Holmes).—It is probably obtained from a species of *Richardsonia.* It occurs in very short fragments, 2 or 3 cm. long, and 2 or 3 mm. in thickness; some nearly cylindrical, others narrowly fusiform; others again formed of roundish or pyriform segments, somewhat thicker than the preceding, placed end to end. The color is generally of a gray-brown, darker than that of the other kind. The longitudinal striæ are fine, and regular on the transverse section. The cortical portion is horny, and its consistence firmer than in the larger kind; the wood is yellowish, and porous. The presence of the starch granules is another of the distinguishing characters of this variety. It contains a larger proportion of emetine than the preceding, yielding, according to the analysis of Pelletier, 9 per cent.

White Ipecac is obtained from *Ionidium Ipecacuanha* St. Hil. (fam. *Violaceæ*). It is obtained from Brazil. The root is much branched, free from annulations and of a grayish-white or light brownish-yellow color. The bark is very thin and the wood is light-yellow and porous. It is distinguished by the presence of stone cells and freedom from starch. It contains inulin and no emetine.

According to Pelletier, 100 parts contain 5 of an emetic substance, 35 of gum, 1 of nitrogenous matter, and 37 of lignin. (*Histoire abrégée des Drogues simples,* i, 514.)

The root of a species of *Ionidium* growing in Quito has attracted some attention as a remedy in *elephantiasis,* under the South American name of *cuichunchulli.* The plant received from Bancroft the name of *I. Marcucci;* but Hooker found the specimen received from Bancroft to be the *I. parviflorum* of Ventenat. Lindley thinks a specimen he received under the same name from Quito to be the *I. microphyllum* of Humboldt. If useful in elephantiasis, it is so probably by its emeto-purgative action. (See *A. J. P.,* vii, 186.)

Under the name of *East Indian Ipecac* there has appeared in the London markets a root of a pale pinkish-brown color, tapering rapidly from the base to the apex, and having annulations much closer than in the true ipecac. It is especially distinguished from the latter root by being evidently monocotyledonous—that is, without the central woody column—the vascular bundles appearing under a pocket lens as a more or less irregular ring of brownish dots. R. A. Cripp obtained from it a minute quantity of an alkaloidal substance, certainly distinct from the alkaloids of ipecac. (*P. J.,* lv.) Ranwez and Campion have also described a false ipecac derived from a monocotyledonous plant, *Cryptocoryne spiralis.* (*Ann. Pharm.,* i.)

In 1866 the cultivation of ipecac was introduced into India by King, but it was not until twenty years later (1886), when it was found that ipecac flourished in the Straits Settlements equally as well as in the Province of Minas, Brazil, that its cultivation became successful.

Cephælis acuminata Karsten is the source of the drug of commerce known as *Cartagena, Panama,* or *Savanilla Ipecac.* The plant is indigenous to Colombia. The leaves according to Karsten are elliptical, pointed, the stipules being separated, often almost to their base in a subulate fringe. The root is much larger and the percentage of active constituents is different from that of Rio ipecac. Humboldt considered *C. acuminata* merely as a different geographical form of *C. Ipecacuanha.* Owing to the scarcity of Rio ipecac the importations of the Cartagena variety is considerable, at times being the only form obtainable. It was for this reason that it was included in the U. S. Pharmacopœia. Braun discussed the subject of the cultivation of ipecac (*Der Pflanzer,* Tanga, i, p. 50) and commented on the available varieties to be selected and the best methods for collecting and treating the drug. Derry states (*C. D.,* lxxx, p. 822) that when established it grows well on virgin soils or where there is a depth of vegetable humus and the situation is moist and shady, but the properties of the root deteriorate with continued cultivation.

Properties.—Rio ipecac is in pieces 2.4 to 4 mm. thick, variously bent and contorted, simple or branched, consisting of an interior slender, light straw-colored, ligneous cord, with a thick, brittle, brownish, finely wrinkled, cortical covering, which presents on its surface a succession of circular, unequal, prominent rings or rugæ, separated by very narrow fissures, frequently extending nearly down to the central fiber. This appearance of the surface has given rise to the term *annelé,* or *annulated,* by which the true ipecac is designated by French pharmacists. The cortex is hard, horny, and

semi-transparent, breaks with a resinous fracture, and easily separates from the tougher ligneous fiber, which possesses the medicinal virtues of the root in a much inferior degree. On microscopic examination the very thick bark is seen to be formed of uniform parenchymatous cells, without traces of the medullary rays, which are very distinct in the woody central cylinder. Attached to the root is frequently a smoother and more slender portion, which is the base of the stem, and should be separated before pulverization. Pereira has met, in the English market, with distinct bales composed of these fragments of stems, with occasionally portions of the root attached. Much stress has been laid upon the color of the external surface of the ipecac root, and diversity in this respect has even led to the formation of distinct varieties. Thus, the epidermis is sometimes deep brown or even blackish, sometimes reddish-brown or reddish-gray, and sometimes light gray or ash-colored; hence the varieties of ipecac root which were formerly recognized, the *brown, red* and *gray*. It is now known that the color of the root varies according to the circumstances of growth and soil, so that coloration as the basis of classification has been abandoned, and the ipecacs of commerce are divided according to their geographical sources, into the *Brazilian* or *Rio Ipecac,* the *Cartagena* or *Colombia Ipecac,* and the *Johore* or *Indian Ipecac;* of these, the two varieties which are recognized by the U. S. Pharmacopœia are described as follows: "*Rio Ipecac.*—In cylindrical pieces, curved, and sharply flexuous, occasionally branched, from 3 to 15 cm. in length and from 2.4 to 4 mm. in thickness; externally dark brown, closely annulated, with thickened, incomplete rings, and usually exhibiting transverse fissures with vertical sides; fracture of bark short, of wood tough, bark very thick, light brown, easily separable from the yellowish-white wood; odor very slight, distinctive, the dust sternutatory; taste bitter and nauseous, somewhat acrid. Stems cylindrical, attaining a length of 10 cm. and a thickness of 2 mm., dark brown, finely longitudinally wrinkled and with a few elliptical scars. *Cartagena Ipecac.*—Cylindrical or slenderly fusiform, more or less tortuous, from 3 to 12 cm. in length and from 4 to 6.5 mm. in thickness; externally grayish-brown, the annulations usually not so numerous as in Rio Ipecac, occasionally transversely fissured and with circular scars of roots; bark 2 mm. in thickness, dark brown, smooth, somewhat horny, and easily separable from the light brown wood. Stems attaining a length of 10 cm. and a thickness of from 2 to 3 mm., cylindrical, somewhat zigzag, due to the prominent nodes with their elliptical stem-scars, grayish or dark brown and longitudinally wrinkled; bark thin. The powder from both varieties of Ipecac is light brown; starch grains numerous, single or from 2- to 4- or more compound, the individual grains spherical or polygonal, from 0.003 to 0.017 mm. in diameter; calcium oxalate in raphides, from 0.015 to 0.04 mm. in length, few; tracheids with bordered pores and oblique slit-like pores. The stem bark shows a few, slightly elongated stone cells, from 0.03 to 0.045 mm. in length with thick lignified walls and simple branching pores. Ipecac yields not less than 1.8 per cent. nor more than 4.5 per cent. of ash." *U. S.*

"In somewhat tortuous pieces seldom more than fifteen centimeters long or six millimetres thick; from dark brick-red to very dark brown; closely annulated externally, the annulations not taking the form of narrow ridges partially encircling the root (distinction from Cartagena ipecacuanha). Fracture short, the fractured surface exhibiting a thick greyish bark and small dense wood. Bark consisting of thin-walled parenchymatous cells, some containing slender raphides, but most filled with simple or compound starch grains, the simple seldom exceeding fifteen microns in length; wood consisting chiefly of tracheids and containing no vessels or typical medullary rays. In the powdered Root, thin-walled parenchymatous tissue, abundant simple or compound starch grains, the single grains seldom exceeding 15 microns in diameter, acicular calcium oxalate crystals, fragments of brown cork, lignified tracheids and wood-parenchyma; but not more than a very occasional vessel or strongly thickened sclerenchymatous cell. Slight odor; taste bitter. Ash not more than 5 per cent. Yields not less than 2 per cent. of alkaloids when tested by the following process." *Br.*

"**Assay.**—Introduce 10 Gm. of Ipecac, in No. 80 powder, into a 250 mil flask, add 100 mils of ether and proceed as directed under *Belladonnæ Radix,* page 222, fifth line of the Assay, beginning with the word "Stopper." Modify the process there given by using 50 mils of the ether solution, representing 5 Gm. of Ipecac, to complete the assay. Use ether instead of chloroform for the final shaking out of the alkaloid, and dissolve the alkaloid from the residue in 10 mils of tenth-normal sulphuric acid V.S.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 24 milligrammes of the ether-soluble alkaloids of Ipecac." *U. S.*

"Shake 7 grammes of the Root, in No. 60 powder, frequently during 5 minutes with 70 millilitres of a mixture of 1 volume of *chloroform* and 3 volumes of *ether;* add 5 millilitres of *solution of ammonia* and shake frequently during one hour; then add 5 millilitres of *water* or sufficient to make the powder agglomerate on violently shaking. Separate 50 millilitres of the clear liquid, and shake first with 10 millilitres of *N/10 solution of hydrochloric acid,* and then with three successive portions, each of 3 millilitres, of *water.* Mix the several aqueous solutions, make alkaline with *solution of ammonia,* and shake out first with 10 millilitres and then with three successive portions, each of 5 millilitres, of a mixture of 6 volumes of *ether*

and 1 volume of *chloroform*. Mix the several ethereal solutions, evaporate, dry the residue at 80° C. (176° F.) and weigh. It weighs not less than 0.100 gramme. Powdered Ipecacuanha Root, when used for official purposes other than the production of standardised preparations, must be adjusted, if necessary, by the addition of powdered Milk Sugar to contain in 100 grammes when tested by the foregoing process 2 grammes of the alkaloids of Ipecacuanha Root. *Limit of error* 0.1 gramme in excess or defect." *Br.*

Cartagena ipecac is usually to be distinguished from the Brazilian by its lighter color and the fact that many of its roots are scarcely at all annulated, and some are even smooth. On the other hand, in most specimens of Carthagena ipecac which we have examined, some of the roots could not be distinguished from those of the Brazilian variety. The cultivation of ipecac, which was introduced into India by the British Government, has especially succeeded in the neighborhood of Johore (Straits Settlement). On account of the great local demands in India, only a small amount of this ipecac comes into general commerce, and very little of it reaches the United States. *Johore* or *Indian ipecac* is especially characterized by the excellent appearance, regularity and large size of the roots, which are deeply annulated, somewhat light in color, and having to a marked degree the general physical and microscopical characteristics of the Brazilian root. Beilee asserts that the Indian ipecac is usually inferior to the Brazilian, yielding only 0.54 per cent. of emetine (*Bull. Soc. de Pharm. de Bordeaux*, xlvi, p. 171), but according to Ransom, Paul and Cownley, and to Umney and Swinton, it is very rich in alkaloids, and, like the Brazilian root, has for its dominant alkaloid, emetine. (See *P. J.*, vol. 63, 69, 70.) Many years ago there was imported from Carácas into the United States a large gray ipecac with badly marked rings. This variety disappeared for a time but is probably the *Colombian* or *Cartagena Ipecac* of modern commerce. It is quite common to find in commerce mixtures of Rio and Cartagena ipecac. These are usually distinguished from each other by the larger size of the starch grains and crystals which occur in the Carthagena variety. (See Schneider, *Jour. of Pharmacology* (N. Y. C. P.), 1897, p. 1; and Collin, *J. P. C.*, xx, p. 293.) Hartwich (*Ap. Ztg.*, xxvi, p. 57), however, points out that the size of the starch grains is not sufficient to differentiate these varieties and states that there is a greater difference in the cells of the woody portion of the root.

Ipecac of commerce is occasionally adulterated with the roots of other plants, the following having been recently reported: Mannich and Brandt (*J. P. C.*, xx, p. 276) have found pieces of *Heteropteris pauciflora*, which do not contain either starch or raphides. Farwell (*D. C.*, li, p. 459) obtained a so-called ipecac from South America which contained no alkaloids. Schneider reports (*Pacific Pharm.*, v, p. 177) the presence of *Asclepias* and a *Spurge* or *Euphorbia*. He also states that the drug is adulterated with foreign roots and with roots of related plants, excess of stems, clay, dirt, infusional earth and cereals. Kraemer (*Proc. A. Ph. A.*, 1900, p. 214) has published a note on a so-called ipecac which proved to be derived from *Polygala angulata* D.C. The best work on the differentiation of ipecac; cephaëline hydrobromide crystallizes that of Hartwich. (*A. Pharm.*, 1904, p. 677; 1905, p. 647.) Tunmann (*Gehe and Co., Handelsbericht*, 1912, p. 165) has submitted this drug to pyroanalysis and obtained characteristic sublimate crystals. For elaborately illustrated articles upon the microscopy of ipecac and its adulterations, see Henry G. Greenish, *P. J.*, 1895, 685, and Albert Schneider, *Am. Drug.*, 1897. According to Greenish, the distinctive characteristics of the powder of either Brazilian or Cartagena ipecac are: (a) the form and size of the starch grains; (b) the absence of vessels, presence of perforated trachoides; (c) the acicular raphides; to these may be added (d) the emetine reaction with chlorine. The stem may in either case be distinguished from the root (in powder) by the presence (a) of sclerenchymatous cells; (b) of lignified cells of the pith; (c) of spiral vessels.

According to the researches of A. R. L. Dohme (*A. J. P.*, 1895), the stems adhering to the ipecac roots contain from fifteen to twenty per cent. less of the alkaloids than do the roots themselves. Moreover, it appears to be established that the portions of the stem distinct from the root contain much less of the alkaloids than does the base of the stem, so that the Pharmacopœia very properly directs that not more than 7 cm. of the stems shall be allowed. The bark of ipecac root should make eighty per cent. of the whole. When the bark in either variety of ipecac is opaque, with a dull amylaceous aspect, the root is less active. As the woody part is nearly inert, and much more difficult of pulverization than the cortical it often happens that, when the root is powdered, the portion last remaining in the mortar possesses scarcely any emetic power, and care should be taken to provide against any defect from this cause. The German Pharmacopœia provides for the rejection of the last fourth of the powder.

The alkaloid emetine found in ipecac by Pelletier, in 1817, was shown by Paul and Cownley (*A. J. P.*, 1895, p. 256, and 1901, p. 87) to consist of three alkaloids, *emetine, cephaëline,* and *psychotrine*. J. U. Lloyd reports the presence of another alkaloid which he calls *hyptonine*. More recently, Hesse (*P. J.*, 1914, xciii, p. 425) has found two new bases, *ipecamine* and *hydroipecamine*. Willigk discovered *ipecacuanhic acid*, which was shown by Reich (*A. Pharm.* (2), cxiii, p. 208) to be a glucoside and to have the formula $C_{14}H_{18}O_7$. Finnemore and Braithwaite (*Trans. Br. Ph. Con.*, 1912, p. 496) confirmed the glucosidal nature of this body and suggested the name *ipecacuanhin*.

There has been considerable dispute as to the composition of the ipecac alkaloids, especially of emetine. The United States Pharmacopœia, following Kunz-Krause, gives $C_{30}H_{44}O_4N_2$. The latter considers the structural formula to be $C_{26}H_{27}(OCH_3)_4(OH)N_2$. Carr and Pyman (*Proc. Chem. Soc.*, 1913, xxix, 226), however, believe that the proper formula for emetine is $C_{29}H_{40}O_4N_2$, and Windaus and Herman (*Ap. Ztg.*, 1914, 443) give $C_{30}H_{42}O_4N_2$. Both Hesse, who accepts the formula for emetine of Kunz-Krause, and Carr and Pyman regard emetine as the oxy-methyl ether of cephaëline. Carr and Pyman give for the formula of cephaëline, $C_{28}H_{38}O_4N_2$, but Hesse gives the structural formula of cephaëline, $C_{25}H_{28}(OCH)_3(OH)N_2$, in harmony with his formula for emetine. According to Carr and Pyman, psychotrine has the formula $C_{28}H_{36}O_4N_2$, and yields, on reduction, cephaëline and isocephaëline. According to Paul and Cownley, the melting point of emetine is 60° C. (140° F.), of cephaëline 102° C. (215.6° F.), and of psychotrine 138° C. (260.4° F.). Psychotrine and its salts are rapidly decomposed on exposure to light, in this respect differing from emetine and cephaëline, neither of which are affected by light. It crystallizes from ether, in prisms of lemon-yellow color.

The medicinal virtues of ipecac reside chiefly, if not solely, in the alkaloids emetine and cephaëline. Different samples of ipecac root vary not only in the total percentage of alkaloidal contents, but also in the proportion of the alkaloids, and the question whether Rio and Cartagena ipecac ought to be considered as interchangeable remedies has become one of importance. Paul and Cownley (*A. J. P.*, 1901, lxxiii, 57), as the result of an exhaustive study, found that the two ipecacs do not differ materially in the total amount of alkaloid contained, but that whereas in the Brazilian root emetine is the dominant alkaloid, in the Colombian root cephaëline predominates, and that therefore the two roots cannot be considered as therapeutically identical. This work of Paul and Cownley has been confirmed by Carl Lowin (*A. I. P. T.*, 1902), so that it would appear to be settled that in general terms Rio ipecac contains 1.5 per cent. of emetine and 0.5 of cephaëline; Cartagena contains 0.9 of emetine and 1.2 of cephaëline. The practical accuracy of these researches, however, has been challenged by the large dealers in the products of ipecac. In 1903, as the result of twenty assays of different lots of each drug, Caeser and Loretz, of Halle, report the results given in the following table:

Formerly Brazilian ipecac commanded in the American market a higher price than did the Carthagena variety. At times the Carthagena ipecac has been from ten to fifteen cents a pound higher than the Brazilian, indicating that in some way it especially recommends itself to the manufacturing pharmacists.

W. G. Whiffen patented in Germany in 1898 a process for making emetine, basing it on the separation of emetime hydrobromide from extract of ipecac; cephaëline hydrobromide crystallizes with great difficulty, while emetine hydrobromide is easily crystallized and separated. (*C. D.*, 1898, 694.)

According to the researches of Tokuye Kimura (*A. J. P.*, 1903, 1), ipecacuanhic acid occurs as a brown, hygroscopic, amorphous mass, freely soluble in warm water and alcohol but very slightly soluble in cold water or ether, insoluble in chloroform, having the formula $C_{17}H_{26}O_{10}$ or a multiple of the same. As a glucoside it is allied to the saponin acids but has no hæmolytic action and does not form soapy solutions. Its most characteristic reaction is that its solution strikes with ferric chloride a green alizarin tint, which, by the addition of ammonia or saturated baryta water, changes to violet or blackish, with the final separation of a blackish-brown precipitate. On the addition to the discolored solution of diluted hydrochloric acid the green color returns. According to the experiments of Kimura, ipecacuanhic acid is readily absorbed but is possessed of feeble physiological activity and is not germicidal, so that the value of ipecac in dysentery can scarcely depend upon its presence.

Flückiger (*Ph. Ztg.*, 1886, p. 30) gave a process for assaying ipecac, which consists in exhausting 10 to 15 grammes of the drug in very fine powder with boiling chloroform to which a drop of solution of ammonia has been added; the extraction is continued until the chloroform passing through shows no sign of alkaloid when treated with acidulated water. Upon distilling off the chloroform, the emetine is left in a very pure condition, and may be dried at 100° C. (212° F.) and weighed, or perhaps more conveniently titrated with Mayer's reagent. He found the average quantity of emetine in ipecac root not to exceed 1 per cent. (*P. J.*, 1886, 643.) H. W. Jones approves of this method, and modifies it by treating the residue from the chloroformic solution with water and diluted sulphuric acid, filtering, and recovering the alkaloid by means of chloroform and ammonia. (*P. J.*, 1886, p. 277.) For other methods, see a paper by A. B. Lyons, *A. J. P.*, 1885, pp. 531,

	Total Alkaloids.	Emetine.	Cephaëline.	Ash.
Rio (Mato Grosso Root)	2.73	1.98	0.50	3.34
Rio (Bahia Root)	2.19	1.36	0.63	3.21
Indian from Johore	2.45	1.46	0.62	2.93
Cartagena	2.75	1.47	1.39	6.02

542; also Lyons' *Assay of Drugs,* 1899, 181, 187.

Uses.—Ipecac was employed as an emetic by the natives of Brazil when that country was first settled by the Portuguese, but, though described in the work of Piso, it was not known in Europe until 1672, and did not come into use until some years afterwards. John Helvetius, grandfather of the famous author of that name, having been associated with a merchant who had imported a large quantity of ipecac into Paris, employed it as a secret remedy, and with so much success in dysentery and other bowel affections that general attention was drawn to it, and the fortunate physician received from Louis XIV a large sum of money and public honors on the condition that he should make it public.

Ipecac is in large doses emetic, in smaller doses, diaphoretic and expectorant, and in still smaller, stimulant to the stomach, exciting appetite and facilitating digestion. In quantities not quite sufficient to cause vomiting, it produces nausea, and frequently acts on the bowels. As an emetic it is mild, but tolerably certain, and free from corrosive or narcotic properties. The emetic effect seems to be due partly to the local irritant effect of the drug upon the mucous membrane of the stomach, although the experiments of Hatcher show that there is some direct stimulant action upon the vomiting center in the medulla. Of the two alkaloids to which the drug owes its activity it would seem from the experiments of Wild (*L. L.,* 1895, ii, p. 1274) that cephaëline is much more active as an emetic than emetine, although the latter is capable, in sufficient dose, of causing vomiting. Because of the promptness with which the emesis occurs it is scarcely possible for enough of the active principles to be absorbed from the stomach to produce direct systemic effects. When injected subcutaneously or intravenously in large dose, however, the alkaloids act as depressants to the motor side of the spinal cord and probably also to the respiratory center. It would seem that they have some special predilection for the lungs for after toxic doses alternating areas of pallor and intense hyperemia have been found in the pulmonary tissue.

Originally introduced into Europe as a remedy for *dysentery,* ipecac for centuries was alternately lauded as a specific and condemned as useless in this disease. In 1911 Vedder (*Bull. Manila Med. Soc.,* March, 1911; also *J. A. M. A.,* 1914, lxii, p. 501) showed that an infusion of ipecac representing one part of the drug in ten thousand destroyed the viability of the *Entamœbæ,* and that the alkaloid emetine in a one to one-hundred thousand solution had the same effect. He also showed that the drug was possessed of no bactericidal virtues. Since this research reasons for the diversions of opinion as to the usefulness of ipecac are apparent. There are two types of dysentery, one due to a specific amœba and the other caused by a bacillus. In the latter form of the disease the drug is useless but is probably the most efficacious remedy we possess in the amœbic type of dysentery. The great difficulty in its employment has always been to obviate the emetic effect which sometimes made it almost impossible to get enough of the drug into the intestinal tract to have an effect. In 1912 Rodgers (*B. M. J.,* 1912, i, p. 1424, and ii, p. 405) introduced the hypodermic administration of the alkaloid emetine which has since then become the standard treatment of *amœbic dysentery.* For this purpose from one to three grains of the emetine hydrochloride (0.065–0.2 Gm.) should be injected daily; preferably divided into two or three doses. The treatment is also of value in the various sequelæ of dysentery, such as *abscess of the liver,* although it does not always produce complete cures. In 1914 Smith and Barrett (*J. A. M. A.,* 1914, lxiii, p. 1746) brought forward evidence that *pyorrhea alveolaris,* or *Rigg's disease,* is due to a specific amœba, and suggested the use of emetine in its treatment. Their discovery has been confirmed by Bass and Johns (*J. A. M. A.,* 1915, lxiv, p. 553) and others. Smith and Barrett recommended the direct application of a 1 per cent. solution directly to the pus pockets but Bass and Johns prefer the hypodermic administration.

As an emetic ipecac is rarely used merely for the purpose of evacuating the stomach, but when an action upon the portal circulation is desirable, as in the so-called *biliousness* or *acute alcoholism,* it is often of service. Many clinicians believe that it has a direct influence upon hepatic secretion, but it is more probable that its effects upon the liver are due simply to its emetic action. By virtue of their nauseating effect small doses of ipecac tend to increase various secretions of the body, thus it is widely used as a diaphoretic, especially in combination with opium (see *Pulvis Ipecacuanhæ et Opii*) in the early stages of *acute coryza* and other mild infections. In the same way it acts as an expectorant, and in the early stages of *acute bronchitis* it is one of the most valuable remedies we possess. Many years ago Trousseau affirmed that ipecac possessed valuable hemostatic powers, especially useful in *hemoptysis,* but this use of it failed to receive general recognition. The treatment has been revived by Flandin (*Press. Med.,* 1913) and other French clinicians.

As an emetic ipecac may be given in substance in the dose of twenty to thirty grains (1.3–2.0 Gm.), repeated in fifteen to twenty minutes if necessary. As an expectorant the syrup is generally preferred. If ipecac itself is used in dysentery it should be given in doses of five grains every hour combined with opium to prevent vomiting. To obviate the nauseating effect of emetine when given by the mouth, Bass and Johns have used a combination with Lloyd's reagent.

Under the name of *riopan,* a preparation asserted to contain 50 per cent. of combined cephaëline and emetine has been introduced. This is marketed in the form of tablets each containing one-thirtieth of a grain (0.002 Gm.), which is

stated to be equivalent to about a grain and a half of ipecac (0.096 Gm.).

Dose, emetic, twenty to thirty grains (1.3–2.0 Gm.); nauseating, two grains (0.13 Gm.); diaphoretic, one grain (0.065 Gm.); stomachic, one-fourth to one-half grain (0.016–0.032 Gm.).

IPOMŒÆ RADIX. Br.

ORIZABA JALAP ROOT [Mexican Scammony Root]

(ī-pō-mœ'æ rā'dix)

"Orizaba Jalap Root is the dried root of Ipomœa orizabensis, *Ledanois.*" *Br.*

Orizaba Root, Male Jalap, Light, Woody, or Fusiform Jalap; Jalap stalks; Purgo Macho (*Mexican*).

The genus *Ipomœa* (Fam. *Convolvulaceæ*) comprises about 300 species of herbs and shrubs, some being erect, others prostrate, but very many climbing. They are remarkable for their showy flowers, as in *I. purpurea,* the common morning glory of the garden. Many of the species produce large tuberous roots which contain a drastic purgative resin. *Orizaba* (also known as *light* or *fusiform*) *Jalap Root* has been recently introduced into the British Pharmacopœia as a source of scammony resin. The plant yielding it (*Ipomœa orizabensis*) is indigenous to Mexico and produces a large, fusiform, more or less branching root attaining a length of 5 dm., yellow on its outer surface, milky-white within. The stem is cylindrical, slightly villous and climbing. The leaves are large, petiolate, cordate, acuminate and villous on the veins. The corolla is campanulate and reddish-purple. The capsule is 2-locular and one seeded.

The drug occurs in transverse slices of the root, or in pieces of irregular shape made by vertical section of these slices. The horizontal cut surface is dark from exposure, unequal from the greater shrinking in desiccation of some parts than others, and presents the extremities of numerous fibers, which are often concentrically arranged. Internally the color is grayish, and the texture, though much less compact than that of jalap, is sometimes almost ligneous.

It is officially described as follows: "In irregular, tough, or fibrous pieces of varying size and shape, but often in portions, three to five centimetres wide and two to four centimetres thick, of transverse slices of large roots. Externally greyish-black and wrinkled, internally greyish or brownish. From the transverse surface coarse fibres protrude in irregular concentric circles. Slight odor; taste faintly acrid. Yields to *alcohol* (90 per cent.) a resin which has the properties enumerated under 'Scammoniæ Resina.'" *Br.*

See also under *Jalap* for further facts concerning these substances.

Ipomœa root has purgative properties similar to those of true jalap, but is less powerful. It is stated (*J. P. C.,* xxiv, 166) that thirty to sixty grains (2–3.9 Gm.) are required to act effectively. It is, however, rarely employed and is official only as a source of scammony resin.

ISPAGHULA. Br.

ISPAGHULA

(is-pag'hū-la)

"Ispaghula consists of the dried seeds of Plantago ovata, *Forsk.*" *Br.*

Ispaghue, Spogel Seeds.

Plantago ovata (*P. Ispaghula* Roxb.) is a herbaceous plant (Fam. *Plantaginaceæ*) growing in India and Persia and extending westward to Spain and the Canary Islands. It is either erect or decumbent and varies in height from 2.5 cm. to 1 dm. The leaves are ovate and either glabrous or shaggy hairy. The flower spikes are either cylindrical or reduced to a globular head. The seeds closely resemble those of other species of *Plantago.*

They are described as follows: "Seeds boat-shaped, somewhat acute at one end, from two to three millimetres long and from one to one and a half millimetres wide; pale greyish-brown, with a darker elongated spot on the convex side; on the concave side the hilum covered with the remains of a thin white membrane. In *water* the testa swells, producing a viscous mucilage. No odor or taste." *Br.*

The seeds of the *Plantago amplexicaulis* Cav. are also sold in the Indian bazaars as Ispaghula. They resemble the official seeds, but are of a darker color.

They yield to water a viscid mucilage. They are used in India as a demulcent in *dysentery* and various intestinal irritations, and are also slightly laxative. On roasting they are said to become astringent, and as such are used for *diarrheas,* especially of children. By European practitioners they have been chiefly employed in *chronic diarrhea.* In India they are also used for their demulcent effect in catarrhal conditions, especially of the genito-urinary tract.

Dose, from one to two and a half drachms (3.9–9.8 Gm.).

Off. Prep.—Decoctum Ispaghulæ, *Br.*

JALAPA. U. S., Br.

JALAP Jalap.

(jạ-lā'pạ)

"The dried tuberous root of *Exogonium Purga* (Wenderoth) Bentham (Fam. *Convolvulaceæ*), yielding not less than 7 per cent. of the total resins of Jalap." *U. S.* "Jalap consists of the dried tubercules of Ipomœa Purga, *Hayne*." *Br.*

Radix Jalapæ, Radix Ipomœarum; Jalap Tubéreux ou officinal, *Fr. Cod.*; Tubera Jalapæ, *P. G.*; Jalape, Jalapenknollen, Jalapenwurzel, *G.*; Gialappa, Sciarappa, *It.*; Jalapa (Raiz de), *Sp.*

The precise botanical origin of jalap remained long unknown. It was at first ascribed by Linnæus to a *Mirabilis*, and afterwards to a new species of *Convolvulus*, to which he gave the name of *C. Jalapa*. The correctness of the latter reference was generally admitted, and, as the *Ipomœa macrorrhiza* of Michaux, growing in Florida and Georgia, was believed to be identical with the *C. Jalapa* of Linnæus, it was thought that this valuable drug, which had been obtained exclusively from Mexico, might be collected within the limits of the United States; but the error of this opinion was soon demonstrated. John R. Coxe, of Philadelphia, received living roots of jalap from Mexico in 1827, and succeeded in producing a perfect flowering plant, of which a description was published by Nuttall (*Am. J. M. S.*, Jan., 1830). The same plant has since been cultivated in various parts of Europe, and has been introduced into the Neilgherry Hills of India, where it grows vigorously. J. H. Balfour (*Curtis's Bot. Mag.*, Feb., 1847) maintains that the plant belongs to the genus Exogonium of Choisy, as defined in De Candolle's *Prodromus*, being distinguished from Ipomœa by its exserted stamens. Bentham and Hooker, however, do not acknowledge the validity of the various genera into which Ipomœa has been broken up by Choisy (*Genera Plantarum*, ii). Engler and Prantl have restored the genus *Exogonium* [*E. Purga* (Wender.) Benth.] for the plant yielding the root called jalap.

The root of *Exogonium Purga* (*Ipomœa Purga* Hayne) is a roundish, somewhat pear-shaped tuber, externally blackish, internally white, with long fibers proceeding from its lower part, as well as from the upper rootstalks. A tuber, produced by Coxe, was, in its third year, between two and three inches in diameter. The stem is round, smooth, much disposed to twist, and rises to a considerable height upon neighboring objects, about which it twines. The leaves are petiolate, heart-shaped, entire, smooth, pointed, deeply sinuated at the base and prominently veined on their under surface. The lower leaves are nearly hastate or with diverging angular points. The flowers, which are large and of a lilac-purple color, stand upon peduncles about as long as the petioles. Each peduncle supports two or, more rarely, three flowers. The calyx is without bracts, five-leaved, obtuse, with two of the divisions external. The corolla is funnel-form. The stamens are five in number, with oblong, white, somewhat exserted anthers. The stigma is simple and capitate.

The jalap plant is a native of Mexico, where it is dug during the whole year, and usually dried over the hearths of the Indian huts. It derives its name from the city of Jalapa, in the state of Vera Cruz, in the neighborhood of which it grows, at the height of about 6000 feet above the ocean. The drug is brought from the port of Vera Cruz in bags containing usually between 100 and 200 pounds. The amount of jalap annually invoiced through the Vera Cruz consulate to the United States is about 200,000 pounds. The jalap plant is now successfully cultivated in the government cinchona plantations in India. Analyses of the Indian tubers show that when grown on fresh soil they contain from 16 to 17 per cent. of resin, and that by manuring the percentage is notably increased, even to 22 per cent. It has also been cultivated in Jamaica, South America and Ceylon. The jalap grows freely in the south of England, but the season is too short for the production of seed by it, although the root has yielded 11.97 per cent. of resin. (*P. J.*, Feb., 1869.) For an account of the cultivation of jalap in Madras, see *Am. Drug.*, 1896, 127.

Properties.—Jalap is officially described as follows: "Fusiform, irregularly ovoid or pyriform, upper end more or less rounded, lower end slightly tapering, the large roots often incised or cut into pieces; from 4 to 15 cm. in length and from 12 to 60 mm. in diameter; externally dark brown, longitudinally wrinkled or furrowed and with numerous lenticels; hard, compact, not fibrous; when broken, internally dark brown, mealy or waxy, bark from 1 to 2 mm. in thickness outer bundles separated from the outer cortical layer by a distinct, brown cambium zone; odor slight but distinctive, smoky; taste somewhat sweet and acrid. The powder is light brown; starch grains numerous, single or 2- to 3-compound, and more or less swollen, ellipsoidal or ovoid with concentric or excentral lamellæ and radiating clefts or fissures, from 0.003 to 0.035 mm. in diameter; calcium oxalate in rosette aggregates from 0.01 to 0.035 mm. in diameter; tracheæ short, wide, with simple or bordered pores; lactiferous vessels with yellowish-brown, resinous masses. Jalap yields not more than 6.5 per cent. of ash." *U. S.*

"Tubercules dark brown, irregularly oblong, napiform or fusiform, three to eight centimetres or more long, the larger being often incised. Hard, compact and heavy; externally wrinkled, and marked with small transverse scars; internally yellowish-grey to dingy brown. In transverse section irregular, dark, concentric lines; examined microscopically numerous compound starch grains, many of which are gelatinised, cluster-crystals of calcium oxalate, and cells containing a resinous emulsion stained yellow by *N/10 solution of iodine;* in the wood, pitted

vessels and tracheids. Characteristic odor; taste at first sweet but afterwards acrid and disagreeable. Ash not more than 6.5 per cent. Yields not less than 9 or more than 11 per cent. of resin having the properties of Jalap Resin, when treated by the process described under 'Jalapæ Resina.'" *Br.*

Jalap is usually kept by pharmacists in the state of powder, which is of a yellowish-gray color, and when inhaled irritates the nostrils and throat, and provokes sneezing and coughing. Jalap yields its active properties partly to water, and completely to diluted alcohol.

"**Assay.**—Pack 10 Gm. of Jalap, in No. 60 powder, in a cylindrical percolator and extract it with alcohol until the percolate measures 100 mils. Transfer 20 mils of the percolate to a separator, add 20 mils of chloroform, mix the liquids, then add 20 mils of distilled water and shake the mixture thoroughly. When the liquids have completely separated, draw off the chloroform into a tared beaker, wash the contents of the separator by rotating with 5 mils of chloroform and draw it off into the beaker. Evaporate the chloroform solution on a water bath, add about 2 mils of alcohol, again evaporate, and then dry the residue to constant weight at 100° C. (212° F.). The weight will be the amount of total resins from 2 Gm. of Jalap." *U. S.*

Buchner and Herberger supposed that they had discovered a basic substance, which they called *jalapin.* G. A. Kayser found that the resin of jalap previously discovered by Cadet de Gassicourt consists of two portions, one of which, amounting to seven parts out of ten, is hard and insoluble in ether, the other is soft and soluble in that menstruum. The hard resin he named *rhodeoretin,* and found to be identical with the jalapin of Buchner and Herberger. By reaction with the alkalies it is converted into an acid, called *rhodeoretinic acid.* Rhodeoretin is slightly soluble in water, freely so in alcohol, and insoluble in ether, chloroform, or benzene, and the alcoholic solution is precipitated both by ether and water. It is dissolved by solutions of the alkalies, more quickly if heated, and is not precipitated by acids, having become soluble by conversion into the acid above referred to. It purges violently in the dose of three or four grains, and is supposed to be the active principle of jalap. Mayer confirmed and extended the observations of Kayser. He gave the name of *convolvulin* to Kayser's rhodeoretin, and stated its formula as $C_{31}H_{50}O_{16}$. This substance is colorless when pure, dissolving easily in ammonia water, and is not reprecipitated by acids, because of its conversion into *convolvulinic acid,* which is a hydroxide of the glucoside convolvulin. This, on being treated with nitric acid, yields *sebacic acid.* Convolvulin possesses in a high degree the purgative properties of jalap. A. Kromer (*Ph. Z. R.,* 1894, Nos. 1–7) also made a study of convolvulin. He finds it to be lævogyrate, and gives it the formula $C_{31}H_{108}O_{27}$, which was later changed (*Die Glykoside,* Van Rijn, 1900, p. 391) and is now given by Hoehnel as $C_{54}H_{96}O_{27}$, which is deduced from its analysis and decomposition products; alkalies decompose it into one molecule of volatile *methylethyl-acetic acid,* $C_5H_{10}O_2$, one molecule of *purginic acid,* $C_{25}H_{46}O_{12}$, and one molecule of *convolvulinic acid,* $C_{45}H_{80}O_{28}$. (See also *A. Pharm.,* 1901, 373.) This latter is amorphous, yielding a white hygroscopic powder soluble in water and alcohol, insoluble in ether; strong sulphuric acid colors it red or brown-red; by the action of acids one molecule of convolvulinic acid yields five molecules of a glucose and one molecule of *convolvulinolic acid,* $C_{15}H_{30}O_3$, which is insoluble in water, melts at 51.5° C. (124.7° F.), is not colored by sulphuric acid, and is isomeric with jalapinolic acid and scammonolic acid, both of which melt at from 63° to 64° C. (145.4°–147.2° F.). Mayer obtained from *Ipomœa orizabensis* a resin which he called *jalapin,* which was afterwards shown by Keller to be identical with the resin of scammony. Mayer's jalapin differs from convolvulin in being soluble in ether. The formula of jalapin, according to Samuelson, is $C_{34}H_{56}$

1. *Action of solvents.*

Solvent.	Jalapin.	Convolvulin.
Chloroform.	Readily soluble.	Slightly soluble.
Ether.	Very soluble.	Insoluble.
Petrol. naphtha.	Slightly soluble.	Insoluble.
Oil of turpentine.	Slightly soluble.	Insoluble.
Benzene.	Slightly soluble.	Insoluble.
Carbon disulph.	Easily soluble.	Insoluble.
Water.	Slightly soluble.	Slightly soluble.
Hydrochloric acid.	Slightly soluble.	Readily soluble.
Sulphuric acid.	Very soluble, with production of maroon color changing to black.	Readily soluble, with production of bright red coloration.
Potassium hydroxide.	Easily soluble.	Easily soluble, with production of odor of whisky when heated.
Ammonia water.	Readily soluble, more so than convolvulin.	Slightly soluble.

2. *Reactions with Oxidizing Agents on convolvulin and jalapin dissolved in concentrated sulphuric acid.*

Agent.	Jalapin.	Convolvulin.
Potassium dichromate.	Produces odor of rancid butter and reddish-brown color.	Produces odor of rancid butter and olive-green color.
Potassium permanganate.	Same reactions.	Same reactions.
Potassium nitrate.	Same reactions, but not so strong.	Same reactions.
Potassium chlorate.	Same reactions, but not so strong.	Same reactions.
Manganese dioxide.	Same odor, and color dark green.	Same odor, and color rose-pink.

O_{16}. Poleck (*A. J. P.*, 1892, p. 465) continued the investigation of the jalapin from *I. orizabensis*, and confirmed the identity of it with scammonin, giving it the formula $C_{34}H_{56}O_{16}$. He suggested that the name of jalapin, which is misleading, should be replaced by *orizabin*. A. F. Stevenson (*N. R.*, 1879, 359) has studied the two resins found in jalap, and furnishes a tabular statement of the differences between the soft resin jalapin and the hard resin convolvulin, which is given in the following table. For the method of obtaining the resin of jalap pure, see *Resina Jalapæ*.

Power and Rogerson report a chemical examination of *Ipomœa purpurea* Roth, known as the common *morning glory*. They conclude that this plant, like many other species of the same genus, contains resins which possess purgative properties, and is thus capable of being used medicinally. (*A. J. P.*, 1908, p. 255.)

Jalap is apt to be attacked by worms, which, however, are said to devour the amylaceous or softer parts, and to leave the resin, so that the worm eaten drug is more powerfully purgative than that which is sound. Thus, out of 397 parts of the former, Henry obtained 72 parts of resin, while from an equal quantity of the latter he procured only 48 parts. Hence, worm eaten jalap should be employed for obtaining the resin, but should not be pulverized, as it would afford a powder of more than the proper strength. The drug is also liable to various adulterations, or fraudulent substitutions, which, however, can usually be detected without difficulty by means of the microscope.

According to Herlant, even in powder it is easy to detect the presence of the root of *Mirabilis Jalapa*, which is sometimes used as an adulterant to jalap, by the presence of raphides of calcium oxalate.

Tampico Jalap (*Purga de Sierra Gorda*, Mexican).—This drug closely resembles in appearance, odor, and taste the true jalap, but the tubers are somewhat smaller, more elongated and shrivelled. According to Ambrose Andouard, it is the *jalap digité majeur* of Guibourt. Through the efforts of Daniel Hanbury, of London, aided by two Prussian officials in Mexico, Hugo Finck, vice-consul at Cordova, and E. Bonecke, consul-general at Mexico, the origin of the drug was traced to the state of Guanajuato, where it grows along the Sierra Gorda, near San Luis de la Paz. In this place it is purchased from the Indians, and conveyed by mules to Tampico, where it enters into commerce. Through the agency of the same gentlemen, Hanbury, after some failures, succeeded in obtaining a living tuber, from which he raised a flourishing plant that proved to be an undescribed species of the genus *Ipomœa*, differing from *I. Purga* by its bell-shaped corolla and pendulous flower-buds. To it Hanbury gave the name *I. simulans*. (*A. J. P.*, July, 1870.) H. Spirgatis, of Königsberg, obtained a resin by preparing a tincture of the Tampico jalap, evaporating, washing, boiling the residue in water, redissolving in alcohol, and decolorizing by charcoal. He gave it the name of *tampicin*. Its physical properties are similar to those of the jalap resin. It is brittle, tasteless, inodorous, insoluble in water, soluble in ether and alcohol, and in solution has a feeble acid reaction. By strong alkalies it is changed into a soluble acid which Spirgatis calls *tampicic acid*. By the action of diluted sulphuric, nitric, or hydrochloric acid, it is converted, slowly if cold, but rapidly with heat, into a peculiar acid called *tampicolic*, with sugar. For the mode of preparing these acids, and their properties, the reader is referred to an article in *N. R.*, July, 1871, p. 50. The melting point of tampicin is 130° C. (266° F.); its formula is $C_{34}H_{54}O_{14}$. The percentage of it yielded by the drug varies from a minimum of 10 per cent. (Hanbury) to a maximum of 15 per cent. (Umney). Andouard states that it is purgative.

The average percentage of resin in Jalap has of late years distinctly lessened; indeed this fact has received official recognition. The U. S. P., 1890, required 12 per cent., and the French Codex, 1884, 16 to 18 per cent. Much of the commercial jalap is far below the lowered official standard, and this appears to be due, not, as believed by Flückiger, to the extraction of the resin from the roots in Mexico, but to the fact that the wild tubers are collected indiscriminately from November to March; the cultivators of India are very careless in their methods. The lowness of the U. S. P. standard (7 per cent.) is to be regretted, especially as the Br. Ph. requires 11 per cent., but it is probably necessary, practically, to meet the commercial conditions. The German Pharmacopœia of 1900, however, requires 9 per cent. From a compilation by M. I. Wilbert (*J. A. Ph. A.*, 1914, 1286) the range of 173 reported analyses of jalap was from 3.67 per cent. to 21.76 per cent. (For various analyses of commercial Jalap, see *U. S. D.*, 18th ed., also *J. P.*, lxxii, p. 152.)

A comparison of various methods of assay was made by Dr. P. Seidler (*Ph. Ztg.*, 1912, No. 2, 15), who recommends the process of the P. G.V., which he says can be still further improved.

The question as to possible substitutes for the official species is also growing in importance. Flückiger pointed out that the seeds of the *Ipomœa hederacea* (see *Kaladana*) yield 8 per cent. of resin identical with that obtained from *Ipomœa Purga*, and the British Pharmacopœia now recognizes *Kaladana* and its resin. Shimoyama, of Tokio, has shown that jalap resin can be obtained from the *Ipomœa triloba* (*Pharbitis triloba*) of Japan. M. K. Hyrano confirms this, and states that the seeds of the plant have long been used in Japan, under the name of "*kengashi*." (For details and method of extracting the resin, see *P. J.*, Oct., 1888.)

Jalap should be rejected when it is light, of a whitish color internally, of a dull fracture, spongy, or friable. Powders of calomel and jalap, taken on long voyages to southern climates, are said, when brought back, to have be-

come consolidated, and so far chemically altered as plainly to exhibit globules of mercury. This change is ascribed by Schacht and Wackenroder to a fungous growth. (*A. Pharm.*, xxxix, 239.)

Uses.—Jalap is an active cathartic, operating briskly and sometimes painfully upon the bowels, and producing copious watery stools. The aqueous extract purges moderately, without much griping, and is said to increase the flow of urine. The portion not taken up by water gripes severely. The aqueous extract obtained from jalap, previously exhausted by rectified spirit, is said to have no cathartic effect. Jalap was introduced into Europe in the latter part of the sixteenth or the beginning of the seventeenth century, and at one time ranked among the purgative medicines most extensively employed. It is applicable to most cases in which an active cathartic is required, and from its hydragogue powers is especially adapted to the treatment of *dropsy*. It is generally given in connection with other medicines, which assist or qualify its operation. In dropsical complaints it is usually combined with potassium bitartrate.

The combination of jalap with calomel has long been popular, in the United States, in *bilious fever* and other complaints attended with *congestion of the liver* or portal circle. In overdoses jalap may produce dangerous hypercatharsis. It is said to purge when applied to a wound. Jalapin when taken internally is probably absorbed, but as yet its presence has never been detected in the urine, and it remains uncertain whether it is eliminated or destroyed. Müller (*In. Dis.*, Dorpat, 1885) found traces of it in the blood, and even in the heart, lungs, and spleen of cats poisoned with it.

The *dose* of jalap, in powder, is from ten to twenty grains (0.65–1.3 Gm.).

KALADANA. Br.

KALADANA [Semen Pharbitidis, Pharbitis Seeds]

(kă-lă-dă'nă)

"Kaladana consists of the dried seeds of Ipomœa hederacea, *Jacq.*" *Br.*

Closely allied to *Ipomœa hederacea* is *I. muricata*, the seeds of which are largely imported into Bombay, from Persia, under the name of *tukm-i-nil*. The juice of this plant is employed to destroy bedbugs, and the seeds are said to be identical in their medicinal properties with those of the official plant.

Ipomœa hederacea Jaeq. (*I. cærulea* Kon.; *Pharbites Nil*, Choissy) is a twining annual plant belonging to the *Convolvulaceæ*. It has large blue flowers whence the specific name *Nil* which signifies in Hindustani *blue*. The leaves are three-lobed and the plant, while common throughout India, is found throughout the tropical regions of both hemispheres. Flückiger found it to contain 8.2 per cent. of resin which corresponded in its various properties to the resin of jalap.

Kaladana seeds are in the form of the segment of a sphere, black, somewhat hairy, weighing from one-half drachm to nearly one drachm.

They are described by the British Pharm., 1914, as follows: "Seeds in the form of a segment of a sphere; usually about five millimetres long, but sometimes much smaller; nearly black. In transverse section, minute dark resin-cells in the plaited cotyledons. Slight odor; taste acrid." *Br.*

From them is prepared *pharbitisin, kaladana resin* (*Kaladanæ Resina,* Br.), by digesting the seed with alcohol until exhaustion, and precipitating with distilled water. (For details, see *Kaladanæ Resina.*)

Uses.—Kaladana seeds were used by the Arabian physicians, under the name of *Habbunnil*, and have been recommended as a safe and active cathartic by various English physicians resident in India. Their action is probably similar to that of jalap.

Dose, thirty to forty-five grains (2–3 Gm.).

Off. Prep.—Kaladanæ Resina, *Br.;* Pulvis Kaladanæ Compositus, *Br.;* Tinctura Kaladanæ, *Br.*

KALADANÆ RESINA. Br.

KALADANA RESIN [Pharbitisin]

(kă-lă-dă'nă rę-sī'nă)

"Kaladana Resin is a mixture of resins obtained from Kaladana." *Br.*

The resin is prepared from Kaladana by a process similar to that employed in isolating the resin from jalap. It is as follows: "Exhaust coarsely powdered Kaladana with Alcohol (90 per cent.). Recover most of the alcohol by distillation; pour the concentrated solution thus obtained into eight times its volume of Distilled Water; allow the resin that separates to subside, wash with Distilled Water, and dry at a gentle heat." *Br.*

It is officially described as "in brownish, opaque fragments, translucent at the edges; brittle, breaking with a resinous fracture; readily reduced to a grey powder. Somewhat disagreeable odor, especially when warmed; taste sweetish, acrid. Readily soluble in *alcohol* (90 per cent.); almost insoluble in *benzene, ether, chloroform,* or *carbon disulphide*. When 1 gramme of the powdered Resin is triturated with 20 millilitres of *water* and filtered, the filtrate is almost colorless. A solution of 0.1 gramme in 10 millilitres of *solution of sodium hydroxide,* boiled for a few moments and cooled, when acidified with *hydrochloric acid,* may become opalescent but not immediately turbid (absence of certain other resins)." *Br.*

This resin appears to be identical with con-

volvulin or at least very closely related to it chemically.

Dose, two to eight grains (0.12–0.5 Gm.).

KAOLINUM. Br.

KAOLIN

(kā-o-lī'nŭm)

"Kaolin is a native aluminium silicate, powdered, and freed from gritty particles by elutriation." *Br.* "A native hydrated aluminum silicate, powdered and freed from gritty particles by elutriation." *N. F.*

Terra porcellanea; Porcelain Clay, Bolus Alba; Terre à porcelaine, *Fr.*; Porcellanerde, Porcellanthon, *G.*

This substance was introduced into the U. S. P. VIII for the purpose of forming the basis of the preparation *Cataplasma Kaolini* which was dropped from the U. S. P. IX, but introduced in the N. F. IV.

Kaolin, $Al_2(SiO_3)_3 + Al_2O(OH)_4$, occurs in abundant deposits as a decomposition product of felspar; the latter is a double silicate of aluminium and alkali, and in its weathering, the alkali is gradually eliminated. A pure kaolin contains approximately 47 per cent. of silica, 40 per cent. of alumina, and 13 per cent. of water.

Pure kaolin is almost infusible, but the presence of impurities, notably undecomposed felspar, increases its fusibility greatly. On the other hand, fire clays which are infusible are kaolins containing a considerable amount of free silica.

Large deposits of kaolin have been recently opened in Florida. It is now used extensively for clarifying oils, such as lard and cotton seed oils and mineral lubricating oils.

The British Pharmacopœia describes it as "a soft whitish powder, insoluble in *water,* or in diluted acids. When the product of its fusion with alkalies is digested with *water,* the filtered solution acidified with *hydrochloric acid,* evaporated to dryness, and the residue digested with *diluted hydrochloric acid,* a deposit of silica is obtained, and the supernatant acid solution yields the *reactions* characteristic of aluminium." *Br.*

It is described in the N. F. IV as "a soft, white or yellowish-white powder, or in lumps, insoluble in water, and in cold dilute acids and solutions of the alkali hydroxides. It has an earthy or clay-like taste. When moistened with water, Kaolin assumes a darker color and develops a marked clay-like odor. Mix 1 Gm. of Kaolin with 10 mils of distilled water and 5 mils of sulphuric acid in a porcelain dish; no effervescence occurs. Evaporate the mixture until the excess of water is removed, and further heat the residue until dense white fumes of sulphuric anhydride appear, then add 20 mils of distilled water, boil for a few minutes and filter; there remains on the filter a gray residue of impure silica. To one-half of the filtrate just obtained add ammonia water; a gelatinous precipitate of aluminum hydroxide is obtained which is insoluble in an excess of the reagent. To the remaining half of the filtrate add sodium hydroxide T.S.; a gelatinous precipitate is produced which is completely or almost completely soluble in an excess of the reagent. Rub 2 Gm. of Kaolin in a mortar with 10 mils of distilled water; the mixture does not acquire more than a slight reddish tint on the addition of 0.5 Gm. of sodium salicylate (*iron*). Ignite Kaolin at a red heat; not less than 85 per cent. of a non-volatile residue remains." *N. F.*

It should not be confused with other silicious earths, such as Kieselguhr, which is now official (see *Terra Silicea Purificata*). It should never be used as a filtering medium on account of its property of removing active constituents from solution by its adsorptive properties. (See Scoville, *J. A. Ph. A.*, 1916, v, 506.)

Thomas J. Keenan, in an interesting article in the *Am. Drug.,* 1914, p. 55, gives a history of kaolin and its uses and points out the uncertainty of the product, due to the loose application of the name and proposes that the name be restricted to a compound having the composition $H_2Al_2Si_2O_8 + H_2O$.

Uses.—Various forms of clay have been used in medicine from time immemorial either as external or internal remedies. The value of these appears to reside in their absorbing properties, although there are some who attribute to them direct antiseptic action. The variety commonly known as *Fuller's earth* has a much higher absorbing power than kaolin. Because of its property of absorbing large amounts of liquid, Fuller's earth is used for many pharmaceutical purposes, especially in the preparation of pills. Not only, however, will it mechanically hold considerable liquid, but further has the property of separating many dissolved substances from solutions. To what this adsorbing power—as it is denominated—is owing is at present somewhat obscure, although it appears to be in part dependent upon the colloidal nature of the earth. It will decolorize fluids by adsorption of the coloring matter, will remove many alkaloids and apparently even certain bacterial toxines. Fantus (*J. A. M. A.*, 1915, lxiv, p. 1838) has shown that there is considerable difference in the adsorbing power of various substances sold under the name of Fuller's earth.

Although kaolin has been asserted to possess antiseptic properties there is no convincing proof of this assertion and its almost complete insolubility renders it highly improbable. It is, however, of service in various local infections, but its value in these conditions is generally explicable on mechanical grounds. It has been used with apparently good results in *suppurating wounds, tuberculous ulcers, weeping eczema, ozena, leucorrhea,* and similar conditions where its absorbent powers make it valuable. The claim is made that in many of these conditions because of its very fine pulverization it penetrates into the infected area and carries with it various antiseptics which may have been added. It has been used internally in *Asiatic cholera, gastro-enteritis,* and *dysentery.*

Its effects in the latter conditions are probably those of a protective to the mucous membrane. Its virtues in these conditions appear to be due in part to the adsorption of the irritant secretions, and in part to its protective influence upon the mucous membrane. According to Hess (*J. A. M. A.*, 1916, lxvi, p. 106), it surpasses either bismuth or chalk in lessening diarrhea. Probably by the formation of colloidal compounds it delays the absorption of toxic alkaloids from the alimentary tract, and Fantus has shown that it is an effective chemical antidote in the treatment of *strychnine poisoning*. While the absorption of some alkaloids is delayed more than others, it probably has a wide field of usefulness in poisoning. Kaolin is also widely used in the form of the cataplasm (see *Cataplasma Kaolini*) as a carrier of heat and moisture in various local inflammations instead of poultices. It is also recommended because of its mechanical properties as an aid in cleansing the hands of the surgeon.

Cimolite is a perfumed powder having similar physical properties to kaolin. Kaolin is not easily affected by most chemical reagents, and it forms a good diluent or excipient for silver nitrate, potassium permanganate, or other salts which are decomposed by organic substances.

Dose, one-half to two ounces (15.5–60 Gm.) several times a day.

Off. Prep.—Cataplasma Kaolini, *N. F.*

KAVÆ RHIZOMA. Br.

KAVA RHIZOME

(kă'væ rhī-zō'mą)

"Kava Rhizome is the peeled, dried, and divided rhizome of Piper methysticum, *Forst. fil.*" *Br.* "The dried rhizome and roots of *Piper methysticum* Forster (Fam. *Piperaceæ*)." *N. F.*

Kava, *N. F.*; Methysticum; Kava-kava.

The genus *Piper* includes a large number of sub-tropical plants, which are mostly shrubs, and rarely herbs or trees. A number of the species are of great economic importance. *Piper methysticum* is a shrub, several feet high, indigneous to many of the South Sea Islands. The plant has cordate, acuminate leaves and very short axillary spikes of flowers. The natives prepare a fermented liquor from the upper portion of the rhizome and the base of the stems.

Kava rhizome occurs "in whitish or light brownish-grey irregularly cuboid or roughly wedge-shaped fragments from which the periderm has been sliced off; from one to five centimetres thick. In transverse section, usually exhibiting a central dense pith, surrounded by a distinct ring of narrow, radiating, vascular bundles separated by relatively broad, paler, medullary rays. Fracture starchy. Slight agreeable odor; taste pungent and bitter." *Br.*

The N. F. description is as follows: "Consisting of a large, irregular knotty crown, often 12 cm. or more in diameter, from which proceed numerous, long, cylindrical, tough, nearly simple roots, which tend to fray out into bare, separated fibro-vascular bundles; the crown soft, light, spongy, and granular and very starchy; externally dark-brown or blackish, the crown frequently partly scraped and light brown to light gray; internally white. Odor faint but characteristic; taste aromatic and pungent, slightly bitter, more or less local anæsthesia resulting. The powdered drug, when examined under the microscope, exhibits numerous, simple, or two- to three-compound starch grains, the individual grains being up to 0.045 mm. in diameter, many with radial clefts or triangular fissures at the center; yellow resin and oil cells; narrow sclerenchymatous fibers with thin, strongly-lignified walls; tracheæ with scalariform or reticulate markings, up to 0.15 mm. in width; few nearly isodiametric wood parenchyma from the remains of the stem. Kava yields not more than 8 per cent. of ash." *N. F.*

The pharmacognosy of this drug has been written up by Semenow in *Ap. Ztg.*, 1890, p. 216, and True, *Ph. Rev.*, xiv, No. 2. Powdered Kava consists of numerous starch grains which are either single or 2- to 3-compound, the individual grains having central radial clefts with triangular fissures varying from 0.006 to 0.035 mm. in diameter. The sclerenchymatous fibers have thin walls which are strongly lignified. The tracheæ have scalariform or reticulate markings. The oil cells frequently contain a yellowish resin. The drug should not yield more than 8 per cent. of ash.

Gobley isolated from kava root a crystalline principle (analogous to piperin), *methysticin*, or *kavahin*, which is without odor and taste, and is probably inert. (*J. P. C.*, Jan., 1860.) It possesses the formula $C_{15}H_{14}O_5$, and is the methyl ester of p-piperonyl acetic acid, and when purified forms silky, lustrous needles melting at 138° to 139° C. (280.4°–282.2° F.). Kavahin differs from piperin and cubebin in being colored red by hydrochloric acid, the red color fading on exposure to air into a bright yellow, and in being colored by strong sulphuric acid a purplish violet, which passes into green. In 1844 Morson discovered an active principle, *kawine*. This is a greenish-yellow, strongly aromatic and acrid resin. It was again studied by Cuzaut in 1860, and by Lewin in 1886. This latter investigator separates it into two resins, of which the β-resin is greasy and of a reddish-brown color, appearing in mass almost black. This is less active than the α-resin, which is yellowish-brown, has the characteristic odor of the drug, is freely soluble in alcohol, and placed upon the tongue produces a burning sensation followed by local anesthesia. (*A. J. P.*, 1886, 450.) *Yangonin* is another glucoside which has been studied by Borsche and Gerhardt. (*Riedels Archives*, 1914, 50.) A volatile oil has also been found in the root. (*J. P. C.*, March, 1862.) Lavialle (*L'Union Pharm.*, Jan., 1889) claims to have obtained an alkaloid, *kavaine*. (See also *Proc. A. Ph. A.*, 1897, 564.)

Uses.—Under the names of *Ava* or *Kava* the natives of the Sandwich Islands have used as an intoxicant a beverage prepared from kava rhizome. The intoxication is wholly unlike that caused by alcohol, being of a silent and drowsy character, accompanied by incoherent dreams, with great loss of muscular power, which is probably due to the action of kava resin upon the spinal cord.

The physiological action of kava and its resin has been investigated by L. Lewin (*Piper Methysticum,* Berlin, 1886), and David Cerna (*T. G.,* 1891). The phenomena which follow the hypodermic injection of the fluidextract of kava or of a solution of its resin are, anesthesia at the point of injection, followed, after absorption, by general paralysis, due to a direct action on the motor side of the spinal cord; the motor nerves and the muscles remain intact. The local anesthesia is due to a paralysis of the sensory nerve filaments, and when the resin is brought in contact with the mucous membranes there is a burning pain, followed in time by a complete loss of sensibility, which is remarkably permanent, since Lewin found that from six to seven minims of a solution of kava injected beneath the skin produced a complete loss of sensibility in the surrounding area, which did not pass away for eight days. (*D. M. Ztg.,* Feb., 1886.) The action of the drug upon the circulation is subordinate to its nervous influence, but according to the experiments of Cerna it does stimulate the heart, although it decreases the number of pulsations by stimulating the inhibitory nerve centers. The same investigator found that at first it stimulates, afterwards depresses, and finally paralyzes the respiratory center. The insolubility and irritant action of kava resin has lessened its use as a practical local anesthetic.

As long ago as 1857 kava root was employed in the treatment of *gonorrhea,* and there is much testimony to its value both in the acute and the chronic form of the disease, as well as in *vaginitis, leucorrhea, nocturnal incontinence,* and similar conditions of the genito-urinary tract.

Under the name of *gonosan* a twenty per cent. solution of kava resin in oil of sandalwood is used internally in the treatment of *gonorrhea.* The advantages claimed for it are that it is much less likely to disturb the stomach than sandalwood oil, that it is locally anesthetic and hence relieves the pain and, apparently, also has some anaphrodisiac action. According to Ganz (*All. M. C. Z.,* 1906, p. 213), while not of itself gonocidal it renders the urine permanently antiseptic and so deprives the gonococci of conditions favorable for their growth. The preparation is marketed in capsules containing 0.3 Gm. of which two to four may be given several times a day. (For the methods of determining kava resins in this and similar preparations, see *Ph. Ztg.,* 1914, 284.)

Dose, of kava rhizome, from fifteen to forty-five grains (1–3 Gm.).

Off. Prep.—Extractum Kavæ Liquidum, *Br.,* (*N. F.*).

KINO. U. S., Br.

KINO

(kī'nō)

"The spontaneously dried juice of *Pterocarpus Marsupium* Roxburgh (Fam. *Leguminosæ*)." *U. S.* "Kino is the juice obtained from incisions in the trunk of Pterocarpus Marsupium, *Roxb.,* heated to boiling and evaporated to dryness. Known in commerce as East Indian, Malabar, Madras, or Cochin kino." *Br.*

Gummi (s. Resina) Kino; Indian Kino, Malabar Kino; Kino de l'Inde, *Fr. Cod.;* Kino, *G.;* Goma quino, *Sp.*

The term kino was originally applied to a vegetable extract or inspissated juice taken to London from the western coast of Africa, and introduced to the notice of the profession by Fothergill. Vegetable products obtained from various other parts of the world, resembling kino in appearance and properties, afterwards received the same name, and some confusion and uncertainty still exist, in relation to the botanical and commercial history of the drug. We shall first consider the general properties of official kino, then the several varieties.

Properties.—The official description is as follows: "In small, brittle angular fragments, usually considerably less than 15 mm. in diameter, varying in color from dark reddish-brown to reddish-black; when crushed upon a slide and examined under the microscope the angular fragments are more or less translucent with a glass-like, conchoidal surface, the thinner pieces having a yellowish-red or deep brownish-red color, the pieces often being marked by nearly parallel, curved and straight lines; inodorous; taste very astringent; when masticated it colors the saliva somewhat pink. The powder is of a dark brick-red color; upon the addition of water, the sharp angular fragments assume a deep rich-red color and become more or less rounded and separate into innumerable, small, granular particles among which are a large number of rod-shaped bacteria. On mounting powdered Kino in alcohol the fragments at first assume a deep red color, then mostly dissolve, leaving a number of small, colorless granules and indistinguishable, cellular fragments. Kino is only partly soluble in cold water, and not less than 40 per cent. is soluble in boiling water. The latter solution, when cooled and filtered, shows a faintly acid reaction, gives a dark green precipitate with ferric chloride T.S. and a reddish-violet color with alkalies. The yield of alcoholic extractive is not less than 45 per cent. Kino contains not more than 12 per cent. of moisture, and yields not more than 3 per cent. of ash." *U. S.*

"In small, angular, glistening, opaque, reddish-black, brittle fragments; transparent and ruby-red in thin laminæ. Inodorous; taste very astringent. Almost entirely soluble in *alcohol* (90 per cent.), slowly and incompletely soluble in cold *water,* not less than 75 per cent.

soluble in boiling *water*, the solutions being deep red in color. Almost entirely insoluble in *ether*. An aqueous solution (1 in 20) yields a voluminous reddish precipitate with dilute mineral acids, and, when largely diluted with *water*, a greenish-black precipitate with *T. Sol. of ferric chloride*. Ash not more than 2.5 per cent. In India and the Eastern Divisions of the Empire, Butea Gum (Buteæ Gummi) may be employed in making the official preparations for which Kino (distinguished in commerce as East Indian, Malabar, Madras, or Cochin kino) is directed to be used." *Br.*

If in large masses, it may be reduced without difficulty into minute fragments. It is without odor, and has a bitter, highly astringent taste, with a somewhat sweetish after-taste. It burns with little flame, and does not soften with heat. It imparts its virtues and a deep red color to water and alcohol, but is nearly insoluble in ether. Cold water forms with it a clear infusion. Boiling water dissolves it more largely, and the saturated decoction becomes turbid on cooling, and deposits a reddish sediment. The tincture is not disturbed by water. When long kept, it often gelatinizes, and loses its astringency. (See *Tinctura Kino.*) Kino undoubtedly consists chiefly of a modification of tannic acid or tannin, which has received the name of *kino-tannic acid*, with extractive, gum, and sometimes probably a little resin, but we need a careful analysis of the different well-ascertained varieties. The aqueous solution is precipitated by gelatin, the soluble salts of iron, silver, lead, and antimony, mercuric chloride, and sulphuric, nitric, and hydrochloric acids. The precipitate with iron is of an olive or greenish-black color. The alkalies favor the solubility of kino in water, but essentially change its nature and destroy its astringency.

1. East India Kino. *Malabar Kino.*—This is the variety at present probably most used and most highly esteemed, and the only one recognized by the British and United States Pharmacopœias. Its origin was long unknown. It is now ascertained, through the researches of Pereira, Royle, Wight, and others, to be the product of *Pterocarpus Marsupium*, a lofty tree growing upon the mountains of the Malabar coast of Hindostan. Kino is the juice of the tree extracted through longitudinal incisions in the bark and afterwards dried in the sun. Upon drying it breaks into small fragments, and is put into wooden boxes for exportation. It is collected near Tellicherry, and exported from Bombay. It is sometimes imported into this country directly from the East Indies, but more commonly from London. From a communication in the *Journal of the Asiatic Society of Bengal*, by F. Mason, it appears that kino is also collected in the Tenasserim provinces, in Farther India, and has been exported from Maulmain to Europe. It is produced by a tree called *Pa-douck*, which Christison recognized from a description furnished to him by Begbie, of Maulmain, as *Pterocarpus Marsupium*, so that this kino has the same origin as that from Malabar. *Pterocarpus indicus*, of the Mauritius Islands, where it is known as *sang-dragon*, also yields a red kino to commerce.

When kino is boiled in water, the decoction deposits, on cooling, a bright red substance, and a similar deposition takes place when a cold filtered aqueous solution is long exposed with a broad surface to the air. According to Hennig, kino consists of tannic acid about 40 per cent., with a trace of gallic acid, kinoic acid, pectin, ulmic acid, and inorganic salts, with excess of earthy bases. (See *A. J. P.*, xv, 544.) C. Etti obtained a new constituent, *kinoin*, by extracting kino with ether. He finally adopted the following method as more practicable. One part of gum kino is added to 2 parts of boiling diluted (1 to 5) hydrochloric acid. Kino-red immediately separates as a soft mass, becoming gradually solid on cooling, while the *kinoin*, mixed with a small quantity of kino-red, remains in solution. The solid residue is once more boiled with water, the liquids are united and shaken with ether. The ethereal solution, on evaporation, leaves a crystalline reddish residue, which is dissolved in hot water, on the cooling of which tolerably pure crystals of *kinoin* are obtained. By continued recrystallization they are obtained colorless. Their formula is $C_{14}H_{12}O_6$, and *kino-red* is the anhydride of this:

$$2C_{14}H_{12}O_6 - H_2O = C_{28}H_{22}O_{11}$$

This kino-red heated to 160° to 170° C. (320°–338° F.), parts with a molecule of water and yields a lower anhydride, $C_{28}H_{20}O_{10}$. Both anhydrides are precipitated by gelatin, but kinoin itself is not. When heated with hydrochloric acid to 120° to 130° C. (248°–266° F.), kinoin yields methyl chloride, gallic acid, and catechol, and hence probably has the constitution of a guaiacol or *methyl-catechol gallate*. Kino contains about 1.5 per cent. of kinoin. (*Ber. d. Chem. Ges.; N. R.*, Feb., 1897.) Kremel found Malabar kino, Butea gum, eucalyptus kino, and the kino from *Coccoloba uvifera* to be free from Etti's kinoin, but to contain a body acquiring, like kinoin, a red color with ferric chloride, which proved to be *pyrocatechuic acid;* this was present either alone or mixed with gallic acid. (*A. J. P.*, 1883, 267.) Some doubt was also thrown upon the value of Etti's conclusions by White (*P. J.*, 1903, p. 676), who failed to find several of the constituents reported by Etti. The true chemistry of kino may therefore be considered to be in a somewhat doubtful state. This is probably due to the fact that many different drugs have appeared in commerce under that name. Kino contains in its natural condition an oxidizing enzyme or oxidase which is the cause of the gelatinization which takes place in preparations of this drug. This enzyme can be destroyed by heat and advantage is taken of this fact in making *Tinctura Kino* (which see). In an examination made by David Hooper of ten varieties of East Indian kino, the proportion of

tannic acid was found, after thoroughly drying the kino, to vary from 80 to 97 per cent. of the whole mass. (*Agricultural Ledger of India*, No. 11, 1901.)

It is said that catechu, broken into small fragments, has sometimes been sold as kino. Genuine kino is sometimes substituted by the extract of krameria. The latter is more brittle and dissolves more quickly in water.

2. West India or Jamaica Kino.—This is believed to be the product of the *Coccoloba uvifera* L., or *sea-side grape*. It grows in the West Indies and neighboring parts of the continent. The kino is said to be obtained by evaporating a decoction of the wood and bark, which are very astringent.

Although it has been many years since any large quantity appeared in our markets, it may occasionally be met. It is contained in large gourds, into which it was evidently poured while in a liquid or semi-liquid state, and then allowed to harden. When taken from the gourd it breaks into fragments of various sizes, upon an average about as large as a hazelnut, and having some tendency to the rectangular form. The consistence of these fragments is uniform, their surface smooth and shining, and their color a dark reddish-brown approaching to black. They are, however, neither so glistening nor so black as the East India kino. In mass they are quite opaque, but in thin splinters are translucent and of a ruby redness. They are readily broken by the fingers into smaller fragments, are easily pulverized, and yield a dull-reddish powder, considerably lighter colored than that of the East Indian variety. The West India kino is without odor, and has a very astringent, bitterish taste, with a scarcely observable sweetish after-taste. It adheres to the teeth when chewed, although rather less than the East Indian variety, and colors the saliva red. The solubility of Jamaica kino was very carefully examined by Robert Bridges, who found that cold water dissolved 89 per cent., and alcohol 94 per cent. The portion dissolved by alcohol and not by water was probably of a resinous nature, as it appeared to be viscid, and very much impeded the filtration of the aqueous solution. Considering the nature of this substance, the form of kino in which it was found is probably, like that from the East Indies, an inspissated juice. Guibourt, who states that Jamaica kino is but slightly dissolved by cold water, must have operated on a different product.

3. South American Kino. *Caraccas Kino.*—In 1839, an astringent extract was described which had been introduced into our market, derived from Caraccas, and known by that name to the druggists. It is probably the same as that described by Guibourt, in the last edition of his *History of Drugs*, as the kino of *Colombia*. As imported, this variety of kino is in large masses, some weighing several pounds, covered with thin leaves, or exhibiting marks of leaves upon their unbroken surface, externally very dark, and internally of a deep reddish-brown or dark port-wine color. Some of the masses are very impure, containing pieces of bark, wood, leaves, etc.; others are more homogeneous, and almost free from impurities. The masses are broken up by means of a mill so as to resemble East India kino, from which, however, this variety differs in being more irregular, less sharply angular, more powdery, and less black. In appearance, taste, odor and other sensible properties this kino closely resembles the West India variety. It is not improbable that they are derived from the same plant, and there is no difficulty in supposing that this may be the *Coccoloba uvifera*, as that tree grows as well upon the continent as in the islands. South American kino was found by Bridges to yield 93.5 per cent. to cold water, and 93 per cent. to alcohol; so that, while it has almost the same solubility as Jamaica kino in alcohol, it is somewhat more soluble in cold water. The aqueous solution in this case was not embarrassed by the adhesive matter which impeded the filtration in the former variety, and the want of a minute proportion of resinous matter in the South American kino is the only apparent difference between the two drugs.

4. African Kino.—The original kino employed by Fothergill was known to be the product of a tree growing in Senegal, and upon the banks of the Gambia, on the western coast of Africa, but the precise character of the tree was not ascertained until a specimen, sent home by Mungo Park during his last journey, enabled the English botanists to decide that it was the *Pterocarpus erinaceus* of Lamarck and Poiret. A particular account of *Pterocarpus erinaceus* and its concrete juice, with a figure, by W. F. Daniell, is contained in the *P. J.* for August, 1854 (vol. xiv, p. 55). The importation of African kino has long ceased. In 1896, however, a consignment of African kino reached London. It was examined by E. M. Holmes, who stated that it was evidently yielded by *P. erinaceus*. (*C. D.*, 1896, 226.) It is said to be still used by the Portuguese of Angola, under the name of *Sangue de Drago*. As described by Fothergill, the African kino, for which he proposed the name of *gummi rubrum astringens Gambinense*, was in lumps of about the size of those of gum Senegal or dragon's blood, and so similar in appearance to the latter that a good judge might easily be deceived. These lumps were hard, brittle, opaque, and almost black, but minute fragments were reddish and transparent like garnet. The drug was inodorous, of a strongly astringent and sweetish taste, and soluble in water to the extent of about five or six parts out of seven, forming a deep red astringent infusion. There can be little doubt that this variety of kino is a concrete juice, which exudes either spontaneously or from wounds in the bark, and hardens in the air. (*Med. Obs. and Inq.*, i, 358.)

Macaranga Kino is obtained from *Macaranga Roxburghii* Wright, of the Deccan peninsula. It occurs in the form of odorless, taste-

less tears or irregular masses. The tears have fibrous fractures and when immersed in water yield unravelling fibers giving the appearance of a sea anemone. According to Hooper, this kino yields from 6 to 15 per cent. of a peculiar tannin and is closely allied to Butea kino, from which it is distinguished by fibrous tears and the fact that it contains so much gum which swells without dissolving in water. (*P. J.*, lxvi, 616.)

MYRISTICA KINO.—There has been produced in Southern India a kino consisting of smaller or larger angular pieces, of deep garnet color, in thin fragments, and having the general characteristics of Malabar kino; according to E. Schaer, it is a product of *Myristica malabarica,* of *M. fragrans,* and probably of other species of the genus. In all important respects these kinos are said to correspond with Malabar kino, but to be distinguishable by containing crystals of calcium tartrate. *Myristica Kino* is probably a distinctive product from the so-called *Syndai varnish,* a rich red fluid obtained from the *Myristica gibbosa* Hook. f., and employed in Assam as a varnish. This varnish is highly astringent and after exposure becomes perfectly impervious, the changes being due to the presence of a ferment or enzyme. As has been shown by D. Hooper (*P. J.*, June 20, 1903), Syndai varnish, if kept in corked bottles, gelatinizes in a few weeks. Edmund White made an investigation into the cause of the gelatinization of tincture of kino (*P. J.*, May, 1903), from which it appeared that this phenomenon was due to the presence in the kino of an enzyme belonging to the oxydases, and this enzyme was subsequently isolated by David Hooper from the fresh juice of *Myristica gibbosa.* (*Proc. A. Ph. A.*, 1903, 733.) It is believed by White that this enzyme may be eliminated from the official as well as other kinos by a judicious method of collection, and considers it probable that the following one, adopted by J. G. F. Marshall and described in the "*Agricultural Ledger*" (1900, No. 11, 381), will accomplish this: "A longitudinal cut is made with an axe or knife, called *acha katti,* through the bark of the trees, down to the cambium, about 1½ feet long, and side cuts are made to lead into this. A bamboo tube is then fixed at the bottom of the main incision in order to catch the juice. In the course of about twenty-four hours the flow of gum ceases and the bamboo is taken down. When several of these bamboo cups are nearly full they are taken to headquarters and emptied into a large cauldron and the juice boiled. During the boiling, the impurities, consisting of pieces of bark, wood and leaves, rise to the surface and are skimmed off. When sufficiently concentrated to the consistence of a thick extract it is exposed to the sun, in thin layers, in shallow vessels until it is dry enough to crumble to pieces. The kino is then weighed and packed away in wooden cases." (*P. J.*, 1903, 702.)

Botany or Blue Mountain kino is obtained from *Angophora lanceolata* Cav. Colombo kino is obtained from a number of species of *Angophora.* Hooper (*P. J.*, 1908, xxvii, 161) reports the occurrence of three new astringent plant juices or kinos. They are derived from *Jatropha Curcas,* from South Salem; *Xylia dolabriformis,* from Burma; and *Parkia insignis* ("*Myauk-tanyet*"), also from Burma.

Uses.—Kino is powerfully astringent, and in this country is much used for the suppression of morbid discharges. In *diarrhea,* not attended with febrile excitement or inflammation, it is often an excellent adjunct to opium and the absorbent medicines, and is a favorite addition to chalk mixture. It is also used in *chronic dysentery* when astringents are admissible; in *leucorrhea* and *diabetes;* and in *passive hemorrhages,* particularly those from the uterus and the intestines. The infusion may be made by pouring eight fluidounces of boiling water on two drachms of the extract, and straining when cool; aromatics may be added, if deemed advisable. The dose of this infusion is a fluidounce (30 mils). The proportion of alcohol in the tincture renders it frequently an unsuitable preparation.

Dose, eight to thirty grains (0.5–2.0 Gm.).

KINO EUCALYPTI. Br.

EUCALYPTUS KINO [Eucalyptus Gum Red Gum]

(kī'nō eū-cą-lўp'tī)

"Eucalyptus Kino is an exudation from the stem of various species of Eucalyptus." *Br.*

Eucalypti Gummi, *Br.* 1898; Australian Kino.

Eucalyptus kino is prepared from a number of species of Eucalyptus, but most of the commercial article is prepared from *E. rostrata,* a tree which is very abundant in Western Australia. This tree received its name from the rastrate character of the opercula. Masses of kino are sometimes found in cavities between the wood and the bark, this being due to the evaporation of the sap in these places. It is usually obtained by incising the trees and collecting the exuding liquid which is then dried in the sun. It has been stated that five hundred pounds of the kino are sometimes yielded in a single year by one tree, but this seems to be a great exaggeration. Occasionally the juice reaches England unevaporated. *Kino juice* has a fine deep red color, a slightly aromatic odor, and a decidedly astringent taste, and on evaporation yields a genuine kino in varying amount. It must not be confounded with the so-called *Liquid Kino,* or *apple tree juice,* which is obtained from incisions in the *Angophora intermedia* or *narrow-leaved apple tree* of Australia. This varies from the consistency and colorlessness of water to an orange brown or reddish-brown liquid as thick as molasses. It contains

catechin and tannic acid, and is said to be especially employed for the purposes of tanning nets.

Properties.—Australian kino usually occurs in dark, reddish-brown (not reddish-black) masses or grains, which when sufficiently thin may be translucent and garnet-like. This form of kino is at the present time very largely used and while similar to the official or East Indian Kino in physical and therapeutical properties has not in solution the tendency to gelatinize. For further information concerning it the reader is referred to an elaborate paper on it by J. H. Maiden, in *P. J.*, Oct., 1889; also *A. J. P.*, 1897, 1.

"In very dark reddish-brown grains or small masses. Thin fragments transparent and ruby-red, or garnet-red. Inodorous; taste astringent. Tough and adhering to the teeth when chewed. Not less than 80 per cent. soluble in *water*. Almost entirely soluble in *alcohol* (90 per cent.)." *Br.*

Eucalyptus kino contains catechin, pyrocatechin and kinoin, and in some specimens a volatile oil, giving a slightly aromatic odor to the drug, which is especially developed by hydrochloric acid. J. H. Maiden (*A. J. P.*, 1895, 575) states that Australian kino contains *eudesmin* and *aromadendrin*. The former of these when purified exists as a pure white mass with a luster resembling spermaceti. It is soluble in hot water, but crystallizes out again on cooling. It is soluble in alcohol, ether, acetic ether, and chloroform, but not in benzene, petroleum spirit, or carbon disulphide. It is dissolved by sulphuric acid with a dark color changing to purple, by nitric acid with a beautiful yellow color. Its formula is given as $C_{36}H_{30}O_8$, and its melting point as 99° C. (210.2° F.). The second substance was also obtained crystallized from boiling water, and melted at 162° C. (323.6° F.). No analysis has been made of it.

Uses.—It does not equal kino in astringency. It is used for *diarrheas of relaxation*, and other affections for which kino has been employed, and is also largely employed as the basis of lozenges and gargles for the relief of relaxed conditions of the pharynx.

Dose, from five to twenty grains (0.3–1.3 Gm.).

Off. Prep.—Trochiscus Kino Eucalypti, *Br.*

KRAMERIÆ RADIX. Br.

KRAMERIA ROOT [Rhatany Root]

(krą-mē'rī-æ rā'dīx)

"Krameria Root is the dried root of Krameria triandra, *Ruiz and Pav.* (Peruvian Rhatany), and also of another species of Krameria, probably Krameria argentea, *Mart.* (Pará Rhatany)." *Br.* "The dried root of *Krameria triandra* Ruiz et Pavon, known in commerce as Peruvian Rhatany, or of *Krameria Ixina* Linné, known in commerce as Savanilla Rhatany, or *Krameria argentea* Martius, known in commerce as Para or Brazilian Rhatany (Fam. *Leguminosæ*), without the presence of more than 5 per cent. of stems or other foreign matter." *N. F.*

Krameria, *N. F.*; Rhatany Radix Ratanhæ; Ratanhia, *Fr. Cod.*; Radix Ratanhiæ, *P. G.*; Ratanhiawurzel, *G.*; Ratania, *It.*; Ratania (Raiz de), *Sp.*

The genus *Krameria* was named in honor of J. G. H. Kramer, a physician and botanist of Temesvar, Hungary.

Krameria was dropped from the U. S. P. IX but retained in the British Pharm., 1914, and in the N. F.

Krameria triandra is a shrub, having a long, much-branched, spreading root, of a blackish-red color; with a round, procumbent, very dark colored stem, divided into numerous branches of which the younger are leafy and thickly covered with soft hairs, giving them a white, silky appearance. The leaves are few, sessile, oblong-ovate, pointed, entire, presenting on both surfaces the same silky whiteness of the young branches. The flowers are lake-colored, and stand singly on short peduncles at the axils of the upper leaves. The stamens are three. The nectary is of four leaflets, the two upper spatulate, the lower roundish and shorter. The fruit is globular, of the size of a pea, surrounded by stiff reddish-brown prickles, and having one or two seeds. It is a native of the Peruvian Andes, growing in dry argillaceous and sandy places. It flowers at all seasons, but is at the height of its bloom in October and November. The root is dug up after the rains, and, according to Tschudi, it is especially obtained in the southern provinces of Peru. Closely allied to it is *K. Ixina* L., which yields *Savánilla Rhatany*. It is, however, distinguished by having four stamens, and occurs in Guiana and Northern Brazil. The name *rhatany* is said to express in the tongue of the Peruvian Indians the creeping character of the plant yielding the root.

Para or *Brazilian Rhatany* was described by Berg in 1865, and is believed to be the root of the *K. Argentea*. It closely resembles the Savanilla variety. Two forms of rhatany which Cotton has described as *Black* and *Brown Antilles rhatany* because produced in these islands have been pronounced by Flückiger (*P. J.*, July, 1870, p. 84) to be identical with the Para Rhatany. According to the studies of Dunwoody (*A. J. P.*, 1890) this rhatany contains the same active principles as the root of *K. Triandra*, but in slightly less quantity.

The British Pharmacopœia recognizes two varieties of rhatany, which are described as follows: "Peruvian Rhatany is nearly cylindrical, slightly flexuous, reddish-brown; length variable; thickness not exceeding fifteen millimetres. Cork scaly; fracture splintery; wood yellow. In transverse section, bark bright reddish-brown and occupying about one-third of the radius of the section. Pará Rhatany is cylindrical, nearly straight, dark purplish-brown or almost black, and marked with deep transverse cracks. Fracture short; wood pale reddish-brown. In transverse section, bark dark reddish-brown and occupying about one-half of the radius of the

section. Both varieties inodorous; taste of the bark astringent, of the wood scarcely perceptible. Ash not more than 4 per cent." *Br.*

The N. F. description is as follows:

"**Peruvian Rhatany.**—It consists of a knotty, several to many-headed crown with numerous branching roots, the latter rarely attaining a length of 50 cm. and usually less than 1 cm. in thickness, cylindrical, somewhat tapering, and flexuous or wavy; externally light reddish-brown or brownish-red, more or less marked with dark scaly cork, especially in the upper portion, otherwise nearly smooth, somewhat longitudinally wrinkled and devoid of transverse fissures, fracture of bark slightly fibrous, of wood tough and splintery, the pinkish-brown bark less than one-third of the radius, the wood yellowish or pinkish-white and finely radiate. Inodorous, wood nearly tasteless, bark astringent.

"**Savanilla Rhatany and Para Rhatany.**—Roots usually separate, less flexuous and tapering than those of Peruvian Rhatany, and usually not exceeding 12 mm. in thickness; externally purplish-brown or chocolate-brown and marked with numerous transverse fissures; fracture less tough than that of Peruvian Rhatany; internally the bark and wood darker, the bark about two-fifths or more of the radius and more astringent than that of Peruvian Rhatany. Inodorous, wood nearly tasteless, bark astringent. Powdered Krameria is reddish-brown; starch grains simple or two- to four-compound, the individual grains spherical, ellipsoidal, or plano-convex, and sometimes with a central, radial or star-like cleft, from 0.003 to 0.035 mm. in diameter; bast fibers more or less wavy in outline with very much attenuated ends and with non-lignified walls; tracheæ with simple or bordered pores associated with numerous wood fibers which are narrow-spindle shaped and with thick, porous, slightly lignified walls; numerous cellular fragments with yellowish or reddish-brown walls; calcium oxalate in monoclinic prisms, from 0.01 to 0.1 mm. in length, few or frequently absent. Macerate 2 Gm. of powdered Krameria with 10 mils of alcohol, with occasional stirring for one hour, and filter. The deep reddish colored filtrate obtained yields a dark brownish-red precipitate and a deep orange-red filtrate upon the addition of an excess of alcoholic lead acetate T.S.; this latter filtrate yields no precipitate upon the further addition of a drop or two of alcoholic lead acetate T.S., and yields an olive-brown solution having a purplish fluorescence upon the addition of a drop or two of ferric chloride T.S. Krameria yields not less than 9 per cent. of aqueous extractive and not more than 5 per cent. of ash." *N. F.*

A rhatany appeared not long since in the London market from Guayaquil. It is described as a large woody root from 1 to 5 cm. in diameter. The bark is of a reddish-brown color with blackish streaks, is thin in comparison to the pith, is of a fibrous texture, and is somewhat striated on the surface and dotted over with small warts. It has a very astringent taste, but no marked odor. E. M. Holmes thinks that it is not the product of the genus *Krameria*. According to the analysis of Passmore, *Guayaquil rhatany* contains a larger quantity of tannin than the Peruvian drug, but less than the Para or the Savanilla rhatany. (*P. J.*, 1903, lxxvi, 878.) A spurious rhatany of unknown botanical origin has appeared in the English market coming from Peru. The root is tapering and varies from two to three and a half inches in length, and a quarter to five-eighths of an inch in diameter. The bark is reddish-brown, rough, scaly and longitudinally grooved. The root has a short fracture and a meditullium of about 24 wedge shaped bundles, is odorless and of an astringent taste. For detailed macro- and microscopical descriptions, see P. H. Marsden, *P. J.*, 1901, 618.

According to an analysis made in the University of Wisconsin, the *Krameria lanceolata* Torrey, of North America, yields 34.5 per cent. of extract and 17 per cent. of tannin, and is therefore richer than the official drug. When treated with iron it strikes a deep-purple color, and is thus easily distinguished from Para rhatany, which gives a dirty brown color, and from Savanilla rhatany, which gives a violet color.

As the astringency is much stronger in the cortical than in the ligneous portions, the smallest pieces are preferable, as they contain the largest proportion of the bark. The powder is of a reddish-brown color. The starch grains occur single or two- to four-compound, the individual grains being spherical, ellipsoidal, or plano-convex, and sometimes with a central, radial, or star-like cleft, from 0.003 to 0.035 mm. in diameter. The bast fibers are more or less wavy in outline with very much attenuated ends and with non-lignified walls. The tracheæ possess simple or bordered pores associated with numerous wood fibers which are narrow-spindle shaped and with thick, porous, slightly lignified walls. There are also numerous cellular fragments with yellowish or reddish-brown walls. Calcium oxalate may occur in monoclinic prisms, from 0.01 to 0.1 mm. in length. Macerate 2 Gm. of powdered Krameria with 10 mils of alcohol, with occasional stirring for one hour, and filter. The deep reddish colored filtrate obtained yields a dark brownish-red precipitate and a deep orange-red filtrate upon the addition of an excess of alcoholic lead acetate T.S.; this latter filtrate yields no precipitate upon the further addition of a drop or two of alcoholic lead acetate T.S., and yields an olive-brown solution having a purplish fluorescence upon the addition of a drop or two of ferric chloride T.S. Krameria should yield not less than 9 per cent. of aqueous extract and not more than 5 per cent. of ash.

The virtues of the root are extracted by water and alcohol, to which it imparts a deep reddish-brown color. From the researches of Vogel, Gmelin, Peschier, and Trommsdorff, it appears to contain tannic acid, lignin, and

minute quantities of gum, starch, saccharine matter, and an acid which Peschier considered as peculiar and named *krameric acid.* The tannic acid of rhatany (*krameria-tannic* or *ratanhia-tannic acid*) is separated by treating the ethereal extract of the bark with alcohol, and evaporating the alcoholic solution. It gives a dark-green precipitate with ferric chloride, a flesh-colored one with gelatin, and none with tartar emetic. (Gmelin.) The tannin of rhatany, in the presence of melted potassium hydroxide, is transformed into protocatechuic acid and phloroglucin, and with diluted acids gives glucose and a peculiar red coloring principle called *ratanhia red,* $C_{26}H_{22}O_{11}$. (*J. P. C.,* Jan., 1868, p. 73.) The proportion of red astringent matter obtained by Vogel was 40 per cent. The mineral acids and most of the metallic salts throw down precipitates with the infusion, decoction, and tincture of rhatany, and are incompatible in prescription.

In examining a specimen of extract of rhatany from America, Wittstein discovered an alkaloid, which he thought to be identical with tyrosine. A somewhat different result was obtained by Ruge, who, after an examination, showed that the new alkaloid is not identical with tyrosine, for it has the formula $C_{10}H_{13}NO_3$, while that of tyrosine is $C_9H_{11}NO_3$, but is rather homologous with it. Like tyrosine, it is an amido-acid, and forms salts equally with mineral acids and with strong bases. It was called *ratanhine* by Ruge. Goldschmidt has since shown (*D. C.,* 1914, 17) that the formula of *rhatanin* is $C_{20}H_{43}NO_3$, and that it is a homologue of tyrosine. It is identical with *angelin, geoffrayin,* and *andirin,* which have been described in various plants. He obtained it in crystalline needles, melting at 280° C. (536° F.). (See *A. J. P.,* 1875, p. 266.)

Cold water extracts all the astringency of rhatany, forming a clear deep-red infusion, which upon careful evaporation yields an almost perfectly soluble extract. The root yields its virtues also to boiling water by maceration, but the resulting infusion becomes turbid upon cooling, in consequence of the deposition of apotheme taken up by the water when heated. By boiling with water a still larger proportion of the apotheme is dissolved, and a considerable quantity of the pure tannin becomes insoluble in cold water, and medicinally inert, either by combining with the starch which is also dissolved, or by conversion into apotheme through the agency of the atmosphere. The decoction is, therefore, an ineligible preparation, and the extract resulting from its evaporation, though greater in weight than that from the cold infusion, contains much less soluble and active matter. Alcohol dissolves a larger proportion of the root than water, but this is owing to the solution of apotheme, and the alcoholic extract contains little if any more of the astringent principle than that prepared by cold water, while it is encumbered with much inert matter. (See *Extractum Krameriæ.*)

A very delicate test for the presence of rhatany is given by Glücksmann (*Ph. Post,* 1912, 65), who states that if an extract containing it be diluted with water until almost colorless, the addition of 0.5 Gm. of sodium bicarbonate to 10 mils of the liquid will produce a rose red color.
